Powders; Smokeless ——. A. T. Cocking and Kynoch, Ltd., Birmingham. Eng. Pat. 21,779, Oct 26, 1905.

THE invention consists in the production of a "bulk" powder by forming the nitrocellulose into grains, and causing the grains to revolve over each other, at the same time thoroughly wetting them with a liquid which will act as a solvent for a portion only of the nitrocellulose. About 120 lb. of a mixture of benzene and alcohol are added to 100 lb. of dry nitrocellulose grains, and the digesting of the revolving grains is continued for a length of time depending on the degree of density required. The grains are then poured into 250 lb. of water at a temperature of about 85° C., and the mass quickly agitated to replace the solvent and stop gelatinisation. An increase in the temperature of the water produces a decrease in the density of the grain.—G. W. McD.

Explosives. G. Reschke, Hamburg, Germany. Eng. Pat. 25,781, Dec. 11, 1905.

SEE Fr. Pat. 360,349 of 1905; this J., 1906, 498.—T. F. B.

Explosives; Manufacture of safety ——. B. G. Reschke, Hamburg. Eng. Pat. 12,716, May 31, 1906.

THE invention consists in the addition of fennel, with or without wood pulp, to explosives of the ammonium nitrate class. The following are examples:—(*a*), Ammonium nitrate (69·6 per cent.), potassium nitrate (10), fennel (14·4), dinitrobenzene (1), and copper oxalate (5 per cent.). (*b*), Ammonium nitrate (94·3 per cent.), fennel (3), and wood pulp (2·7 per cent.).—G. W. McD.

UNITED STATES PATENT.

Glycerin nitrates; Manufacture of ——. A. Mikolajczak, Kastrop, Germany. U.S. Pat. 830,909, Sept. 11, 1906.

SEE Fr. Pat. 349,078 of 1904; this J., 1905, 636.—T.F.B.

FRENCH PATENTS.

Explosive. R. Imperiali. Fr. Pat. 364,948, Feb. 22, 1906.

SEE Eng. Pat. 14,545 of 1905; this J., 1905, 1084.—T.F.B.

Nitroglycerin explosives of low freezing point; Method of manufacture of ——. C. Classen. Fr. Pat. 364,803, March 31, 1906.

GLYCEROL is converted by heating at ordinary pressure into diglycerol. This body is then nitrated and used as an explosive either alone or admixed with trinitroglycerol. It is said that the presence of 25 per cent. of this body reduces the freezing point of nitroglycerin explosives to – 18° C.—G. W. McD.

Powder; Manufacture of a smokeless cannon ——. G. Robrecht. Fr. Pat. 364,973, April 6, 1906.

VEGETABLE fibre is immersed for a period of twelve hours in a mixture of three volumes of sulphuric acid and one volume of nitric acid, at a temperature of 25° C. It is then removed, and allowed to stand for a further period of two hours. The nitrocellulose is then, after washing in water, dissolved in acetone or sulphuric acid, re-precipitated by the addition of water, and formed into powder in the ordinary manner.—G. W. McD.

Nitrocellulose; Apparatus and method for the manufacture of ——. J. M. and W. T. Thomson, England. Fr. Pat. 364,981, April 6, 1906.

THE apparatus consists of two vessels placed side by side, furnished with false bottoms, and joined together at their lowest points by a pipe provided with a stop-cock. Each vessel has also a tap for the purpose of emptying. They are used alternately for the nitrating process as follows: One of the vessels is partly filled with nitrating acid, and the cellulose immersed in the usual manner. A thin layer of dilute sulphuric acid is run over the surface of the nitrating acid to prevent fuming. When nitration is complete, water is slowly and carefully run into the nitrating vessel, so as to flow over the surface without mixing. The stop-cock between the two vessels is then opened sufficiently to allow the nitrating acid to pass into the empty vessel at the same rate as the water flows into the other. The whole of the acid contained in the vessel first used is thus displaced by water into the adjoining one, where it is revivified and used for a further process of nitration, after which it is returned by water displacement to the vessel first used, which has then been emptied of its charge of nitrocellulose. (See also Eng. Pat. 8278 of 1903; this J., 1904, 560.)—G. W. McD.

Explosives in mines; Process for destroying the noxious gases resulting from the use of ——. H. Walker. Fr. Pat. 364,999, April 6, 1906. Under Int. Conv., Nov. 21, 1905.

SEE Eng. Pat. 24,002 of 1905; this J., 1906, 609.—T.F.B.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 913.)

APPARATUS, &c.

ENGLISH PATENTS.

Gas calorimeter. J. W. B. Stokes, Shettleton, Lanark., N.B., and D. Stewart and Co. (1902), Ltd., Glasgow. Eng. Pat. 21,872, Oct. 27, 1905.

THE instrument consists of a cylindrical cast-iron vessel, which may be filled to any desired depth with mercury by raising or lowering a mercury reservoir communicating with the vessel by means of flexible tubing, the level being

shown on a gauge glass which may be closed by cocks. Two stop-cocks at the top of the vessel serve for supplying gas and air respectively, and a third one communicates with a pressure gauge. At the upper end of the vessel there is provided a device for electrically igniting the charges, which may consist of a sparking plug of the kind usually fitted to small internal combustion motors, and may be operated by a high tension coil. A water jacket may be provided in order to maintain the vessel at a given temperature. In operation, the vessel is filled with mercury, the gas cock which is connected with the source of gas is opened, and a certain volume of gas drawn in by lowering the mercury reservoir; the gas cock is then closed, the air cock opened, and the requisite quantity of air drawn in. The air cock is then closed, the stop-cock controlling ingress to the pressure gauge is opened, and if any initial pressure of the explosive mixture be desired, the mercury reservoir is raised to a corresponding height. Subsequently the cocks on pressure gauge and level gauge are closed, and the charge is electrically fired. From the pressure then recorded with the proportions, volume, temperature, and initial pressure as factors (which may be made constants), the calorific value of the gas can be easily calculated.—R. L.

Fire damp (methane) or other light gas or gases in mines or other places; Apparatus for detecting the presence and volume of ——. J. McCutcheon, Edinburgh. Eng. Pat. 24,900, Dec. 1, 1905.

The apparatus comprises a U-shaped tube, the right limb of which is connected at the bottom with a third vertical tube, the connecting tube being provided with a stop-cock. The latter tube has an enlargement above the level of the U-tube, and, above this, is connected to an india-rubber ball provided with a tap or valve. In the left limb of the U-tube is a float connected above with a rod of aluminium, the rod terminating in a metal disc coated with platinum foil. This disc is directly opposite the spring terminal of a wire which is connected to one pole of an electric battery, and also to a scale on which the percentage of fire damp is indicated; the rod of the float carries a small platinum wire dipping into a cup of mercury connected with the other pole of the battery. An electric bell or other alarm signal is included in the electric circuit. A mobile liquid, preferably "azine" (paraffin or other mineral oil treated with a vegetable colouring matter), is introduced into the U-tube and the other vertical tube, then the stop-cock between the latter and the U-tube is closed, and the india-rubber ball is compressed to expel air through the valve provided, which valve is then closed. On now opening the tap between the U-tube and the other tube, the liquid in the U-tube is drawn partly into the latter by the vacuum in the india-rubber ball, the float in the U-tube descends, and the electric circuit is broken. The right limb of the U-tube carries at the top a vessel of unglazed earthenware, provided with a tap. If fire damp or other light gas be present, then, owing to endosmose action, the liquid in the U-tube is forced down in the right limb, and up in the left limb, the float rises, the electrical circuit is closed, and the bell rings.—A. S.

Gas analysis; Apparatus for ——. W. H. Sodeau, and Brady and Martin, Ltd., Newcastle-on-Tyne. Eng. Pat. 12,225, May 25, 1906.

The apparatus comprises a water-jacketed measuring vessel, an absorption-pipette, a combustion-pipette, and an aspirator, with the requisite connections. A three-way cock with the handle distinctly marked at one end so as to indicate which way communication has been made is specially claimed. The gas to be examined is measured, the carbon dioxide absorbed in the absorption-pipette, the residue measured, then transferred to the combustion-pipette, wherein any carbon monoxide and hydrogen present are burnt by means of an electric current passed through a platinum spiral. The residue is again measured in order to ascertain the contraction due to combustion, and the carbon dioxide formed is estimated by absorption. Claim is also made for the application of the apparatus, in conjunction with suitable pyrometric or thermometric appliances, for the purpose of determining the efficiency of a boiler or furnace.—A. S.

United States Patent.

Gaseous mixtures; Testing ——. F. Haber, Karlsruhe, Assignor to Carl Zeiss, Jena, Germany. U.S. Pat. 830,225, Sept. 4, 1906.

See Fr. Pat. 356,388 of 1905; this J., 1905, 326.—T. F. B.

INORGANIC—QUALITATIVE.

Nitric acid; Two new colour reactions of ——. C. Reichard. Chem.-Zeit., 1906, **30**, 790—791.

A small volume of the solution containing a nitrate is evaporated to dryness, and a small quantity of arbutin and a drop of concentrated sulphuric acid added, when an intense yellow coloration is produced.

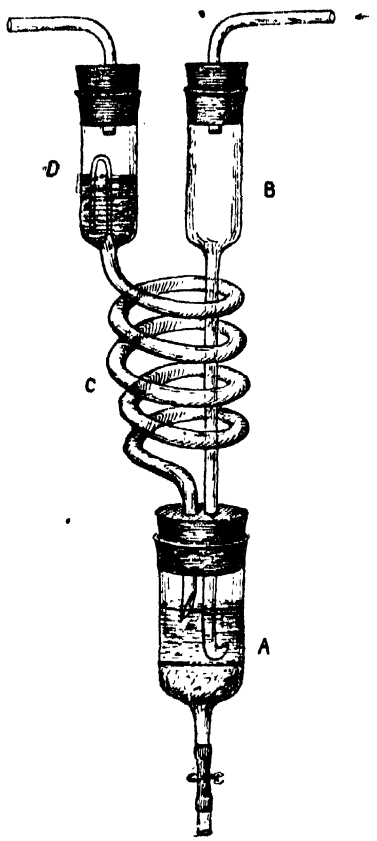
A more delicate reaction consists in moistening a small quantity of berberine hydrochloride with the solution containing nitrate, and adding one drop of concentrated sulphuric acid; a deep reddish-brown coloration is produced. If hydrochloric acid be used in place of sulphuric acid, the coloration appears only on warming. —A. S.

INORGANIC—QUANTITATIVE.

Iron and manganese; Separation of —— from nickel and cobalt by treatment of their sulphides with dilute acids. W. Funk. Z. anal. Chem., 1906, **45**, 562—570.

The author finds that treatment of their sulphides with dilute acids does not afford a quantitative method for the separation of iron from nickel and cobalt, even when formic acid is used instead of hydrochloric acid. It may be used, however, to separate manganese from nickel and cobalt. For this purpose the sulphides of the three metals are treated in the cold with $N/1$ formic acid in such excess that the solution finally contains from 0·5 to 1·5 per cent. of free formic acid. After saturating the liquid with hydrogen sulphide, the manganese solution is filtered from the insoluble sulphides of cobalt and nickel, which are washed with a solution of hydrogen sulphide. In the filtrate all the sulphides are again precipitated and treated as above in order to recover the small quantity of nickel and cobalt dissolved by the formic acid.—A. G. L.

Cement; Influence of the sulphur dioxide contained in illuminating gas on the determination of the loss on ignition of ——. L. von Szathmáry. Z. anal. Chem., 1906, **45**, 600—604.



The author determines the loss on ignition of cement by heating in a platinum crucible over the blow-pipe, and finds it impossible to obtain constant results in this way unless the products of combustion of the gas are prevented from entering the crucible (by means of an asbestos shield), as the cement takes up sulphuric anhydride from the gases. Direct experiments have shown that it is really sulphuric anhydride, and not carbon dioxide, which is absorbed, and also that, of the constituents of the cement, neither alumina nor magnesia, but only lime, takes any part in the reaction.—A. G. L.

Carbon dioxide and carbon [in steel]; Determination of ——. J. Macfarlane and A. W. Gregory. Chem. News, 1906, **94**, 133—134.

For the determination of small quantities of carbon dioxide evolved by the combustion of steel, &c., the authors have devised the combined absorption and filtering apparatus shown (see figure). The base of the funnel, A, is plugged with a filtering layer of glass-wool covered with asbestos or paper pulp. When the apparatus has been freed from carbon dioxide, a measured volume of standard baryta solution is introduced at B, and is caused to rise into the spiral, C, and cup, D, by the passage of a current of air. The gases of combustion, entering at B, are then passed through, and the carbon dioxide is absorbed in the vessel, A, and in the spiral, C; the liquid in the cup, D, should

remain clear. Lastly, the stem of the funnel, A, is opened and the apparatus is washed with boiling water until free from barium hydroxide. The carbon dioxide can be determined either directly by titration of the barium carbonate, or indirectly by precipitating the barium as sulphate.

Larger quantities of carbon dioxide can be absorbed by an ammoniacal solution of barium chloride contained in ordinary flasks. The barium carbonate is precipitated only on boiling. When cold, the precipitate can be

filtered and washed in the open air, without fear of further precipitation of barium carbonate by the carbon dioxide of the air.—J. F. B.

Phosphorus in presence of large quantities of phosphorus sesquisulphide; Detection of small quantities of white ——. L. Aronstein. Chem. Weekblad, 1906, 3, 283—287. Chem. Centr., 1906, 1, 1906.

By means of a T-tube dry hydrogen which has been previously washed with potassium permanganate solution and sulphuric acid, or dry carbon dioxide washed with water and sulphuric acid, is mixed with a small proportion of air, and led over the phosphorus sesquisulphide. If white phosphorus be present, phosphorescence is produced. The phosphorescence disappears if the proportion of air be increased, and reappears if the supply of air be again diminished. Pure phosphorus sesquisulphide, under these conditions, produces phosphorescence only at temperatures above 80° C. It is stated that 0·2 per cent. of white phosphorus can be detected in this manner, provided the absolute weight is not less than 0·04 mgrm. If the material under examination contain oil of turpentine, alcohol, or other volatile substance, phosphorescence appears only after the current of gas has been passing for several minutes.—A. S.

Phosphorus in presence of large quantities of phosphorus sesquisulphide; Detection of small quantities of white ——. L. Aronstein. Chem. Weekblad, 1906, 3, 493—499.

The author states that the lead acetate method recommended by Van Eijk (this J., 1906, 869) is not suitable for the detection of white phosphorus in presence of phosphorus sesquisulphide. Phosphorus is attacked by boiling lead acetate solution, a black precipitate being produced even if air be carefully excluded. Moreover, when phosphorus sesquisulphide is boiled with excess of lead acetate solution, phosphorescence is produced if air be allowed to enter the condenser. The method, also recommended by Van Eijk, in which the residue left after extracting with carbon bisulphide is rubbed in the dark, was only capable of detecting the presence of 1·4 per cent. of phosphorus in phosphorus sesquisulphide in the author's hands. Reference is made to the method previously described by the author (see preceding abstract). —A. S.

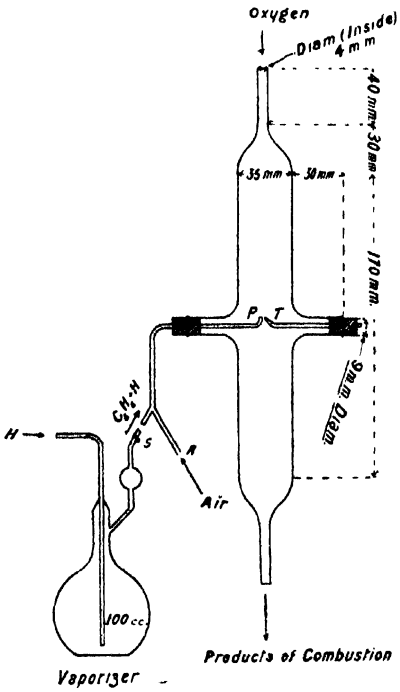
ORGANIC—QUALITATIVE.

Mineral acids in presence of organic acids [in wine and vinegar]; New method for the detection of free ——. O. Carletti. Boll. Chim. Farm., 1906, 45, 449—451. Chem. Centr., 1906, 2, 825.

The Jorissen-Lindet reaction for the detection of furfura in alcohol is based on the formation of basic colouring matters from furfural and aromatic amines. The author finds that if aniline be used as the amine, the reaction takes place only in presence of organic acids, but not with aniline salts of mineral acids, or after addition of mineral acid to aniline salts of organic acids. This fact may be utilised for the detection of small quantities of free mineral acids in wine and vinegar. Two solutions are employed: (*a*) 5 grms. of pure aniline and 20 grms. of concentrated acetic acid diluted to 100 c.c. with water; (*b*) 1 grm. of freshly-prepared furfural diluted to 100 c.c. with 95 per cent. alcohol. Fifty c.c. of the wine (or vinegar), previously decolorised by means of animal charcoal, are treated with 25 c.c. of 95 per cent. alcohol, and 10 c.c. of the mixture are treated with five drops of solution, (*a*), shaken, and mixed with five drops of the furfural solution. If free mineral acid be present (even to the extent of 1 per 1000) in the wine, the liquid retains unaltered its faint greenish tint, but if mineral acids be absent, there is produced almost immediately a distinct pink coloration, which attains its greatest intensity in half an hour.—A. S.

Methyl alcohol; Detection of ——. H. Scudder and R. B. Riggs. J. Amer. Chem. Soc., 1906, 28, 1202—1204.

Leach and Lythgoe (this J., 1905, 943) recommend, as a confirmatory test for methyl alcohol, oxidation through the medium of a hot copper spiral, and testing for formaldehyde by means of milk and hydrochloric acid containing ferric chloride. The authors show that a great number of organic compounds yield, by this treatment, sufficient formaldehyde to give the reaction, and that therefore the test cannot be depended upon to detect methyl alcohol. —J. T. D.



ORGANIC—QUANTITATIVE.

Benzene; Determination of carbon bisulphide and total sulphur in commercial ——. E. S. Johnson. J. Amer. Chem. Soc., 1906, 28, 1209—1220.

Carbon bisulphide.—To 75 c.c. of the benzene contained in a 250 c.c. stoppered flask, alcoholic solution of potassium hydroxide is added (about 1 c.c. of the saturated solution for each 0·1 grm. of bisulphide expected) and agitated for 15—20 minutes. Water is added to dissolve the xanthate formed, and after shaking, the mixture is transferred to a separating funnel, and the xanthate drawn off. The extraction with potassium hydroxide is repeated, using about three-quarters of the original amount, and, if necessary, gone through a third time. The extracts and washings are made up to 500 c.c. An aliquot portion of the solution is acidified with "wall-diluted" acetic acid in not too great excess, and precipitated cold with 20 per

cent. copper sulphate solution, adding the solution in slight excess, and stirring frequently during 1½ hours. The precipitate is filtered off, washed, dried, and ignited in a porcelain crucible. Numerous experiments with varying amounts of carbon bisulphide, varying excess of copper sulphate, and varying intervals of time between filtration and precipitation, showed that the ratio of cupric oxide obtained, to carbon bisulphide present, varied from 1·593 to 1·825; for general practice the working factor of 1·75 is adopted by the author.

Total sulphur.—The principle of the method is the combustion of the benzene (5 grms.) in a stream of oxygen. The apparatus used is shown in the figure.

The sample is contained in the flask. Pure dry oxygen is passed through the combustion chamber from top to bottom, and passes out through two wash-bottles containing jointly 25 grms. of crystallised sodium carbonate dissolved in 110 c.c. of water, to which has been added more than enough bromine water (say 10 c.c.) to oxidise any possible amount of sulphurous acid. The little pilot flame, T, of pure hydrogen is lighted and adjusted in position; the flask is filled with pure hydrogen from another supply, then connected to the A-tube, and the stream of hydrogen continued. The benzene vapour and hydrogen ignite at P, and pure dry air is then sent by A through the A-tube till the flame is but slightly luminous. The flame is kept about an inch in length, and the flask warmed, if necessary, till the whole of the benzene is burnt. This should take about three hours, and the end of the operation is readily seen by the vanishing of the luminosity of the flame. The stop-cock, S, is then closed, the pilot-flame extinguished, the oxygen shut off, and air sent through, first by A, and then from the top, till all traces of the products of combustion have been washed through the absorbing liquid. The sulphur in this liquid is then determined gravimetrically.—J. T. D.

Tannin; Determination of —— in tanning materials Boudet. Bull. Soc. Chim., 1906, **35**, 760—762.

In the estimation of tannin by means of standard iodine and thiosulphate (Jean's method) it is necessary to allow two hours for the reaction between the iodine and tannin before titrating the excess of iodine. One grm. of iodine has been found to react with 1·137 grms. of pure dry tannic acid. Gallic acid behaves similarly, 1 grm. of iodine reacting with 0·467 grm. of this substance. Both tannin and gallic acid may be determined in the same material by treating the extract with standard iodine solution before and after getting rid of the tannin with hide-powder, the difference between the two titration results being calculated as tannin and the second as gallic acid. The end of the titration, using starch indicator, may be seen quite easily even with the highly coloured tanning liquor obtained from cutch.—F. Sodn.

Sugar cane and bagasse; Direct determination of sugar in ——. H. Pellet. Sixth Int. Congr. Appl. Chem., Rome, 1906; Z. Ver. deut. Zuckerind., 1906, 838—840.

The author considers that the method of alcoholic digestion for the estimation of sugar in sugar cane and bagasse should be abandoned, and that the aqueous digestion method should be used instead. He also considers that the single digestion of 20—30 grms. of the ground material with 300—500 c.c. of water does not give a trustworthy result. Owing to the non-homogeneity of the material, 50 grms. should always be taken for analysis, and the sample should be subjected to several successive extractions with boiling water, since one extraction does not suffice to remove all the sugar from the material. The author recommends Zamaron's apparatus for extraction. For practical purposes a modification of the single extraction process may suffice: 50 grms. of the material are extracted with boiling water, the solution is decanted off, and the residual bagasse expressed in an ordinary screw-press, the expressed juice being added to the decanted solution. The author also recommends the estimation of the sugar in the expressed juice alone for the purpose of getting an idea of the amount of sugar lost in the working operations.—L. E.

Polarimetric sugar analysis; Clarification with dry basic lead acetate in ——. W. Horne. Sixth Int. Congr. Appl. Chem., Rome, 1906; Z. Ver. deut. Zuckerind., 1906, 825—827.

According to results published by Watts and Tempany, the ordinary polarisation method in the case of Muscovado and partly refined products gave results which on the average were 0·3 per cent. too high, the error being due to the volume occupied by the lead precipitate. On the contrary, by the use of dry basic lead acetate (according to Horne's clarification method), the results obtained were only 0·04 per cent. too high. H. and L. Pellet have objected to the latter method on the ground that the lead precipitate absorbs sugar, and thereby compensates the error introduced in the ordinary clarification method. (See this J., 1906, 823.) The author has examined this statement, and concludes that the lead precipitate does not absorb sugar. 52·096 grms. of dry granulated sugar were dissolved, and the solution made up to 200 c.c. Of this solution 50 c.c. were made up to 100 c.c., and polarised, the reading being 49·725. Another 50 c.c. of the solution were placed in a 100 c.c. flask, treated with 10 c.c. of an optically inactive organic solution of an earlier lead precipitate, and then with 2 c.c. of basic lead acetate solution, and finally made up to volume with water. The filtrate polarised 49·80. The calculated value (allowing for the volume of the lead precipitate) was 49·755. Hence the value obtained was higher than the calculated one, instead of lower as it should have been if the precipitate had absorbed sugar. In a second experiment four times the amount of organic solution, *i.e.*, 40 c.c., was used, together with 8 c.c. of lead solution. The original solution polarised 49·783, whilst after treatment it polarised 49·916, the calculated value being 49·903, thus showing that no sugar had been absorbed by the precipitate. In another experiment 1 grm. of dry powdered lead precipitate was shaken for 15 minutes with 50 c.c. of a normal pure sugar solution; the polarisation reading was practically unaltered by this treatment. In conclusion the author shows that the very slightly high results obtained by his

method of clarification with dry basic lead acetate are due in part to the presence of insoluble matter in the raw sugar.—L. E.

Sucrose; Polarimetric determination of —— II. F. Watts and H. A. Tempany. West. Ind. Bull., 1906, 7, 132—140.

In continuation of previous work (see this J., 1905, 817) on the changes of the specific rotatory power of cane sugar solutions with changes of temperature, the authors have made further determinations in the following manner: A standard solution of pure cane sugar was made, and its rotation was observed at two extreme temperatures (about 16° and 33° C.), care being taken that the temperature of the instrument and of the whole room in which the observations were made should follow closely the same variations as the temperature of the sugar solution. Having thus determined the total difference of rotation of the same sugar solution at two different temperatures, the following corrections were subtracted from it: (*a*) the expansion of the sugar solution; (*b*) the variation due to the change of the specific rotation of the quartz wedge of the instrument between the same limits of temperature; (*c*) the expansion of the polarimeter tube. The residual difference between the sum of these corrections and the total variation in the rotation of the sugar solution is expressed as the influence of the change of temperature on the specific rotatory power of the sugar. In this manner of working, any errors due to the making up of the solution and to the presence of impurities are eliminated. From their results, which agree well with observations made by Wiley and by Schonrock, the authors deduce the following rule:—"Polarise at the temperature at which the solution is prepared, and correct for temperature by the formula: polarisation + (0·00031 *t*) N, where *t* is the difference between the temperature of observation and that at which the instrument was standardised, and N is the Ventzke scale reading."—J. F. B.

Maple syrup and maple sugar; Determination of "lead number" in ——. A. L. Winton and J. L. Kreider. J. Amer. Chem. Soc., 1906, 28, 1204—1209.

Instead of measuring the volume of the precipitate produced by adding basic lead acetate to maple products (see Hortvet, this J., 1904, 1241), the authors determine the amount of lead in the precipitate. Twenty-five grms. of the material (26·048 grms. if sugars are to be determined polariscopically in the same portion) are weighed into a 100 c.c. flask, 25 c.c. of standard solution of basic lead acetate added, the liquid made up to the mark, shaken, allowed to stand for an hour, and filtered through a dry filter. Ten c c. of the filtrate are taken, diluted to 50 c.c., and precipitated with sulphuric acid and 100 c.c. of 95 per cent. alcohol. The precipitate is allowed to stand over night, filtered in a Gooch crucible, washed with 95 per cent. alcohol, dried, ignited at a low red heat for three minutes, and weighed. The lead in this precipitate, subtracted from the amount in 2·5 c.c. of the standard solution and divided by 2·5, gives the "lead number." The standard lead solution is made by boiling for half an hour 430 grms. of lead acetate and 130 grms. of litharge with a litre of water, allowing to cool and settle, decanting the clear liquid, and diluting to sp. gr. 1·25.

The method gave, on 15 samples of authentic maple syrup (total solids 64 to 68·5 per cent.) and maple sugar (94·6 to 99·2 per cent.) of various qualities, lead numbers of 1·19 to 1·77 for the syrups, and 1·83 to 2·48 for the sugars, whilst 12 adulterated syrups on the market gave lead numbers of 0·02 to 0·92.—J. T. D.

Colchicine; Determination of ——. A. Panchaud. Schweiz. Woch. Chem. Pharm., 1906, 44, 563—564.

1·5 grms. of coarsely powdered seeds are macerated for 30 minutes with 150 grms. of chloroform, with agitation. Six c.c. of a 10 per cent. solution of ammonia are then added, with further thorough agitation for another 30 minutes. 100 grms. of the chloroform extract are then filtered into a tared Erlenmeyer flask, and distilled to perfect dryness. The residue is taken up in 1 grm. of dry chloroform, to which 2 grms. of dry ether are added, followed by 30 grms. of dry light petroleum spirit. The precipitate is collected on a small filter, washed with light petroleum spirit, well drained, and dissolved, and washed back into the empty flask by means of warm chloroform, the filter being thoroughly extracted with the same solvent. The chloroform is again distilled off, and the dry residue, dissolved in 15 drops of chloroform, is again precipitated, as before, with the same quantity of absolute ether and dry light petroleum spirit. The precipitated colchicine is collected on a small tared filter. Any alkaloid adhering to the flask is dissolved in five drops of chloroform, and precipitated with 1 grm. of absolute ether and 10 grms. of dry light petroleum spirit, and transferred to the rest on the filter. The flask and filter contents are then washed with a little petroleum spirit, the filter is drained, dried until constant in weight, and weighed. The weight obtained + 0·0022 grm. × 10 gives the percentage of colchicine in the seeds.—J. O. B.

Methyl alcohol; Detection and determination of —— [in presence of ethyl alcohol]. E. Voisenet. Bull. Soc. Chim., 1906, 35, 748—760.

This is an application of a colour reaction of formaldehyde already described (this J., 1905, 1326) to the detection and estimation of small quantities of methyl alcohol, more particularly in samples of ethyl alcohol. Such a volume of the alcohol is taken as corresponds to 10 c.c. of absolute alcohol. It is diluted to 50 c.c., and 5 grms. of powdered potassium bichromate and 30 c.c. of sulphuric acid (one to five by weight) are added. The mixture is shaken until the bichromate is dissolved, and left for one hour at the ordinary temperature. In this process methylal is produced which readily decomposes to give formaldehyde. The mixture is then distilled very slowly so as to obtain about 30 c.c. of distillate in the first hour. This contains the whole of the acetaldehyde produced, and is rejected. The next 20 c.c. contains all the methylal, and is used for the colour test. To 4 c.c. of this distillate are added 1 c.c. of a solution of albumin and 15 c.c. of hydrochloric acid containing nitrous acid. The albumin solution is prepared by vigorously beating the white of an egg with one-fifth of its volume of distilled water, and straining, the clear liquid thus obtained containing about 10 per cent. of albumin. The nitrous acid solution is made by adding 0·1 c.c. of a 3·6 per cent. solution of potassium nitrite to 200 c.c. of pure concentrated hydrochloric acid. After shaking to dissolve the coagulated albumin, the tube is placed in a water-bath at 50° C. If methylal is present, *i.e.*, if the alcohol contained wood spirit, a violet coloration results immediately or in a few minutes, the maximum colour being developed in 15 minutes. A blank experiment should be carried out under precisely similar conditions, using pure alcohol, and if standard tints are prepared by adding known quantities of methyl alcohol, the reaction may be made quantitative. The standards remain unaltered for some weeks. One part of methyl alcohol in 20,000 parts of ethyl alcohol may be detected, the above directions being most suitable where the proportions lie between one in 10 and one in 1000. If the proportion is found to be greater than one in 50, it is advisable to dilute the distillate for quantitative purposes.

As before described (*loc. cit.*), some other aldehydes and aldehydic phenols give a similar colour by the above treatment, but whereas that with formaldehyde is at once discharged by such reducing agents as sulphuretted hydrogen or sulphur dioxide, a large excess of these reagents and heating is required to destroy the colour produced by other aldehydes. The reaction is therefore characteristic of methyl alcohol and formaldehyde.

—F. Sodn.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Presentations to Sir W. Perkin in America. *Times Oct.* 8, 1906.

Sir William Perkin was the guest of honour at Delmonico's on October 6, at a dinner given by 400 American

iemists and manufacturers of chemical products. Prof. handler presided, and many well-known Americans ere among the guests. Dr. Nichols presented to Sir 'illiam Perkin the first cast of a gold medal to be known i the Perkin medal and to be awarded each year to some merican chemist who has distinguished himself in the eld of research. Another gift to Sir W. Perkin was a lver service as a personal tribute from the chemists and anufacturers who were present.

New Books.

EPORT OF THE INTERNATIONAL COMMITTEE ON ANALYSES TO THE 6TH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY AT ROME, 1906. By Prof. Dr. G. LUNGE. Verlag von Zürcher und Furrer. Zürich. 1906. Price M. 10 or 12.50 frcs.

vo volume, containing 421 pages of subject matter, evoted to the following subjects:—I. By-Laws of the nternational Sub-Committee on Analyses. II. Introuction and Report by the President (G. Lunge). Reports f the 11 Sub-Committees upon the various questions resented.

'OXINES AND ANTITOXINES. By CARL OPPENHEIMER, M.D., Ph.D. Translated from the German by C. A. Mitchell, B.A. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London. 1906. Price 7s. 6d. net.

vo volume, containing 245 pages of subject matter, ollowed by alphabetical indexes of authors and subjects. The text is subdivided as follows:—GENERAL PART.—. Introduction, with definition of a "Toxine," &c. II. Behaviour of Toxines towards Antitoxines. III. Endoxines and Bacterial Proteins. SPECIAL PART.—I. The rue Toxines. II. Endotoxines and other Bacterial Poisons. III. The Vegetable Toxines (*Phytotoxines.*) IV. The Animal Toxines. (*Zootoxines.*)

THE LABORATORY BOOK OF MINERAL OIL TESTING. By JAS. A. HICKS. With introduction by Sir Boverton Redwood. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London. 1906. Price 2s. 6d. net.

SMALL 8vo volume, containing frontispiece (Abel Petroleum Testing Apparatus), preface, 68 pages of subject matter, with 31 illustrations. Appendix, with thermometric tables, and the alphabetical index. The text is classified as follows: I. Specific Gravity. II. Flashing Point. III. Viscosity. IV. Colour. V. Sundry Apparatus.

PRACTICAL METHODS OF INORGANIC CHEMISTRY. By F. MOLLWO PERKIN, Ph.D., head of the Chemistry Department, Borough Polytechnic Institute, London. Archibald Constable and Co., Ltd., London. 1906. Price 2s. 6d. net.

SMALL 8vo volume, containing 152 pages of subject matter, with 27 illustrations, and the alphabetical index. This is essentially a treatise on "Inorganic Methods of Preparation for Students," as defined by the author himself. The text is subdivided and classified as follows:—I. General Methods and Preparations. II. Salts. III. Halogens and Halogen Compounds. IV. Metallic Oxides. V. Acids. VI. Preparations of Metals and Metalloids. VII. Special Preparations. VIII. Tables, Melting Points, and Specific Gravities, Approximate Temperatures, &c. IX. Preparation of some Reagents.

THE EXTRA PHARMACOPŒIA OF MARTINDALE AND WESTCOTT. Revised by W. HARRISON MARTINDALE, Ph.D., and W. WYNN WESTCOTT, M.B.Lond., D.Ph. Twelfth Edition. H. K. Lewis, 136, Gower Street, London, W.C. 1906. Price 10s.

MED. 24mo volume, containing 1075 pages of subject matter, and including an alphabetical index and posological table. The text is classified as follows:—I. New Chemicals, Drugs, and Modes of Treatment. II. Abbreviations, Weights, and Measures, &c. III. Materia Medica, Official and Non-official, alphabetically arranged, also Secondary List of Drugs. IV. Physiological Standardisation, Note. V. Antitoxins, Vaccines, Antitoxic Serums. VI. Animal Organotherapy. VII. Mineral Waters: Nature, Chemical Constituents, Medicinal Uses, and Season VIII. British Health Resorts. IX. Analytical Memoranda. X. Neutralisation Table. XI. B.P. and International (1906) Atomic Weights. XII. Freezing Mixtures. XIII. Percentage and Grains per ounce Equivalents. XIV. Approximate Melting Points of some Fats and Waxes, and Mixtures. XV. Thermometric Equivalents. XVI. Poisons Schedule. XVII. Drop Measure based on the Table in Farmacopea Española. XVIII. General Index and Posological Table. XIX. Therapeutic Index of Diseases and Symptoms.

A HISTORY OF CHEMISTRY. By F. P. ARMITAGE, M.A. Longmans, Green and Co., 39, Paternoster Row, London. Also New York and Bombay. 1906. Price 6s.

8vo volume, containing 254 pages of subject matter, and indexes of names. The text is classified into the following sections:—I. From Earliest Times to the Downfall of "Iatro-Chemistry." II. From Boyle to Lavoisier, and the Establishment of the Quantitative Method. III. From Lavoisier to the Enunciation of the Atomic Theory by Dalton. IV. Dalton's Atomic Theory, and the Work of Davy. V. Berzelius, and the Development of the Atomic System. VI. The Fortunes of the Atomic Theory between the Years 1819 and 1844. VII. Development of Organic Chemistry. VIII. The Radical Theory and Discovery of Substitution. IX. Constitution of Acids and the Differentiation of the Terms Atom, Molecule, and Equivalent. X. Gerhardt's Unitary System. XI. Valency, Chemical Nature of Carbon, and the Constitution of Organic Compounds. XII. Development of Stereo-Chemistry. XIII. Inter-Relationship of Atomic Weights, Cannizzaro's Reform, and the Periodic Law.

JOURNAL OF THE

Society of Chemical Industry.

No. 20.—Vol. XXV. SUPPLEMENT. OCTOBER 31, 1906.

HON. TREASURER:—
Samuel Hall, East London Soap Works, Bow, E.

PRESIDENT:—
Eustace Carey.

GENERAL SECRETARY:—
Charles G. Cresswell.

EDITOR:—
Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

OFFICES:—
59, Palace Chambers, Westminster, S.W.

Telegraphic Address: "Soy Palatable, London." *Telephone No.:* "715, Victoria."

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1s. each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e.).

List of Members Elected.

Oct. 23, 1906.

Barnes, A. G., c/o Grassmoor Co., Chesterfield, Colliery Proprietor.

Barrs, Chas. E., 20, Carlingford Road, Hampstead, N.W., Analyst.

Belden, A. W., Fuel Testing Plant, St. Louis, Mo., U.S.A., Coke Expert.

Bernett, S., 19, St. Dunstan's Hill, London, E.C., Technical Chemist.

Caddick, Arthur, 32, Manor Road, Rugby, Works Chemist.

Carpenter, P. H., 46, Streathbourne Road, Upper Tooting, S.W., Analyst.

Carr, John Trevor, c/o Messrs. C. A. Parsons & Co., Heaton Works, Newcastle-on-Tyne, Chemist.

Chadsey, S. B., c/o International Harvester Co., Hamilton, Ontario, Canada, Chemist.

Clifford, Joseph, 24, Davyhulme Road, Urmston, near Manchester, Chemist.

Cornwall, R. de Vere, Salisbury, Rhodesia, Chemist.

Cunnington, Alfred V., c/o Messrs. Brunner, Mond & Co., Northwich, Cheshire, Manager of Chemical Works.

Dodsworth, Walter A., c/o Journal of Commerce, 32, Broadway, New York City, U.S.A., Newspaper Editor.

Donald, Richard A., 80, King Street East, Toronto, Canada, Wood Distiller.

Elliott, Edward, c/o Reckitt & Sons, Ltd., Bourke Street, Redfern, Sydney, N.S.W., Chemical Engineer.

Epheraim, Dr. Julius, 11 Kantstrasse[illegible], 99, Berlin, S.W., Consulting Chemist and Patent Agent.

Foster, Robert K., [illegible] Victoria Road, Kirkwood, Maidstone, Victoria, Australia, Pharmaceutical Chemist.

Foucar, J. Louis, 20, St. John's Park, Blackheath, S.E., Chemist.

Garroway, Major John, Netherfield Chemical Works, 694, Duke Street, Glasgow, Chemist.

Goldschmidt, Dr. Karl, Chemical Works, Essen-Ruhr, Germany, Manufacturing Chemist.

Hattrick, J. M., 7, Bridge Street, Sydney, N.S.W., Australia, Agronom.

Heys, Chas. H., 124, Yonge Street, Toronto, Canada, Consulting Chemist.

Hickman, T. Moore, Holmdale, Penn Road, Wolverhampton, Analyst.

Hogarth, Julius Wm., 37, Annandale Street, Sydney, New South Wales, Australia, Demonstrator of Chemistry.

John, David, Haileybury, Ontario, Canada, Chemist.

Joshua, Dr. Walter Philip, c/o The Mond Nickel Co., Clydach, R.S.O., South Wales, Chemist.

Lautz, Alfred, Société des Mat. Colorantes et Prod. Chimiques de St. Denis, St. Denis sur Seine, France, Works Manager.

Leigh, Edw. Collier, Caixa 147, Pernambuco, Brazil, Manager of Gas Works.

Marshall, Dexter, c/o McClure Co., Fourth Avenue, New York City, U.S.A.

Mitchell, Oswald H., c/o Basil Turner, Woolwich, Sydney, N.S.W., Australia, Assayer.

Moore, F. H., 39, Lime Street, London, E.C., Analytical Chemist.

Morgan, Thomas, "Meirion," Dovedale Road, Wavertree, Liverpool, Manufacturing Chemist.

Moss, William, Moss Chemical Manufacturing Co., [illegible] Carlaw Avenue, Toronto, Canada, [illegible] Manufacturer.

Muir, William, [illegible] Bridge, [illegible] Scotland.

Oxley, Horace F., c/o British Algin Co; Holywell, North Wales, Chemist.
Phipps, Chas. B., East Rockaway, Long Island, N.Y., U.S.A., Chemist.
Pont, A. Felix du, Box 91, Wilmington, Del., U.S.A., Explosives Manufacturer.
Priestman, E., 17, Falkner Square, Liverpool, Drysalter.
Raymond, R. S., Marshall's Co-operative Breweries Co., Ltd., Paddington, Sydney, N.S.W., Australia, Brewer.
Russell, David, Cadham, Markinch, Fife, N.B., Papermaker.
Seabury, Richard W., c/o Loando Hard Rubber Co., Boonton, N.J., U.S.A., Factory Superintendent.
Sherwin, R. S., c/o Pittsburg Reduction Co., East Street, Louis, Ill., U.S.A., Chemist.
Simons, F. D., Continental Mexican Rubber Co., Epartado 176, Torreon, Mexico, Chemist.
Smith, Charles, Knowsley Road, Smithills, Bolton, Lancs., Science Master.
Stark, Ad. Otto, Saccharin-Fabrik Aktienges. vorm. Fahlberg, List & Co., Salbke Westerhüsen A/E., Germany.
Webb, E. A., 51, Pearson Avenue, Toronto, Canada, Manufacturing Chemist.
Weddell, George, The North Cottage, St. George's, Newcastle-on-Tyne, Manufacturing Chemist.
Wuth, Dr. Berthold, Oaklands, Bramhall, Cheshire, Chemist.

Changes of Address.

Adams, Thos. H., l/o Derby; Endon Villa, Victoria Avenue, Borrowash, near Derby.
Allen, Charles D., jun., l/o Fourth Street; 541, Sixth Street, Brooklyn, N.Y., U.S.A.
Bourne, L. M., l/o Strong Place; 119, Montague Street, Brooklyn, N.Y., U.S.A.
Bradburn, J. A., l/o Willis Avenue; 311, Montgomery Street, Syracuse, N.Y., U.S.A.
Bryant, Arthur P., l/o Winthrop Avenue; 1514, Kenmore Avenue, Chicago, Ill., U.S.A., Consulting Chemist.
Buchanan, E. F., l/o Frankfort; retain Journals.
Dillon, W., l/o Leeds; Highfield, Wetherby, Yorks.
Fillis, Frank, l/o Barry; Brookland, London Road, Neath, South Wales, Cement Works Manager.
Fox, T., jun; all communications to c/o Fox Brothers & Co., Ltd., Wellington, Somerset.
Jackson, Arthur A., l/o Toledo; 672, East 43rd Street, Chicago, Ill., U.S.A.
King, Lieut. A. E., l/o Woolwich; Headquarters, Egyptian Army, War Office, Cairo, Egypt.
Koch, Geo. W.; all communications to Lock Box 12, Woodhaven, N.Y., U.S.A.
Langmuir, F. Leighton, l/o London; 350, Bloor Street West, Toronto, Canada.
Laycock, T. P., l/o London Road; Fletton Spring, Peterborough. Managing Director, Platico Mantle Co.
McIntosh, Jno. C., l/o Michipicoten; Bruce Mines, Ont., Canada.
Matson, F. de, l/o Gainsborough; Fairfield, Chestnut Avenue, Boston Spa, Yorks.
Muschel, H. AH., l/o Saxony; Paper Mill, Altdamm, near Stettin, Germany.
Pennington, Thos. J., l/o Platteville; c/o Mogul Mining Co., Plums, S. Dakota, U.S.A.
Robertson, Jas., l/o Whiffet Street; 6, Windsor Terrace, Lefroy Street, Coatbridge, N.B.
Rosenblatt, A. H., l/o East 92nd Street; Hecksoher Hall, Madison Avenue and 96th Street, New York City, U.S.A., Chemist.
Taylor, G. Sidgley, l/o Great George Street; Caxton House, Westminster, S.W.
Tobin, Stanley, l/o [illegible]; 248, Kingsbury Road, Erdington, Birmingham.
Tonkin, Dr. Wm., l/o [illegible]; Hawthorne Lodge, Leicksford, near Wakefield.
Watson, Herbert W., l/o [illegible] Road; c/o H. Hogarth, Denton Avenue, Chapeltown, Leeds.

Patent List.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 21,716. Robertson. Furnaces. Oct. 2.
„ 21,752. Wilson. Furnaces. Oct. 2.
„ 21,947. Elmore. Apparatus for separating subdivided solid matter from a liquid, particularly applicable for thickening ore pulp. Oct. 4.
„ 22,167. Dopp. Pressure filters.* Oct. 8.
„ 22,187. Burt. Filters.* Oct. 8.
„ 22,446. Taylor. Acid-proof bags and bagging. Oct. 11.
„ 22,512. Carpenter. Distilling apparatus.* Oct. 11.
[C.S.] 20,470 (1905). Sandbach. Cooling or heating apparatus. Oct. 17.
„ 20,646 (1905). Sutcliffe and Speakman. Tunnel kilns for burning bricks, briquettes, and the like. Oct. 10.
„ 14,061 (1906). Rayner. Condensing, cooling, or heating apparatus. Oct. 10.

II.—FUEL, GAS, AND LIGHT.

[A.] 21,654. Johnson (Dr. Hollefreund und Co.). Manufacture of filaments for incandescence electric lamps. Oct. 1.
„ 21,847. Akt.-Ges. f. Selasbeleuchtung. Process for producing a constant mixture of gas and air and apparatus therefor. [Ger. Appl., Oct. 7, 1905.]* Oct. 3.
„ 22,028. Harris. Compositions for use in the production of gas from garbage or similar gas-producing material.* Oct. 5.
„ 32,049. Weigel and Wolf. Steam and gas generators. [U.S. Appl., Oct. 5, 1905.]* Oct. 5.
„ 22,260. Lynde. Apparatus for producing gas from petrol, &c. Oct. 9.
„ 22,571. Atkinson. Incandescent gas mantles.* Oct. 12.
„ 22,677. Exbrayat and Gayda. Manufacture of briquettes from coal dust.* Oct. 13.
„ 20,705. Wilton. Purification of gas and recovery of by-products. Oct. 13.
[C.S.] 14,226 (1905). Glascoe. Carburetted air apparatus. Oct. 17.
„ 19,716 (1905). Doherty. Regulating the temperature of combustion in a gas-producer furnace for heating retort ovens, &c. Oct. 10.
„ 21,405 (1905). Bowmer. Gas producers. Oct. 10.
„ 23,650 (1905). Young and Glover. Process of carbonising coals for the production of illuminating and heating gases and apparatus therefor. Oct. 10.
„ 25,665 (1905). Elsenhans. Purifying gases and otherwise treating gases with liquids. Oct. 10.
„ 667 (1906). Hurlebusch. Movable gas plants. Oct. 17.
„ 5129 (1906). Kuzel. Manufacture of light-emitting bodies for electric glow lamps. Oct. 10.
„ 5222 (1906). Green and Horn. Apparatus for producing gas from petroleum spirit or other volatile oil or spirit. Oct. 10.
„ 11,133 (1906). Burschell. Removing hydrogen sulphide from gases. Oct. 17.
„ 14,901 (1906). Deuts. Gasglühlicht A.-G. Production of metallic electrical incandescence bodies. Oct. 17.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 22,395. Noad and Townsend. Refining mineral oil.* Oct. 10.
„ 22,430. Harris. *See* under XII.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 21,926. Junius. Manufacture of [illegible]. [Ger. Appl., Nov. 7, 1905.]* Oct. 4.
„ 21,949. Elberfeld Farbenf. Bayer & Co. Manufacture of greenish blue [illegible] and derivatives thereof.* Oct. 4.

[A.] 22,021. Rensford (Chemische Fabrik und Co.). Manufacture of sulphones [illegible]. Oct. 5.
" 22,096. Newton (Bayer und Co.). Manufacture of new tetrazo dyestuffs. Oct. 6.
" 22,202. Imray (Meister, Lucius, und Brüning). Manufacture of a new product from anthrathrysone and of nitrogenous derivatives of the anthraquinone series therefrom. Oct. 8.
" 22,236. Johnson (Kalle und Co.). Manufacture of mercurial compounds of *o*-nitrotoluene, and the manufacture of *o*-nitrobenzaldehyde therefrom. Oct. 9.
[C.S.] 5890 (1906). Newton (Bayer und Co.). Manufacture of a new dyestuff of the anthracene series. Oct. 17.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 21,769. Schoop. *See under* XI.
" 21,811. Bradley. *See under* X.
" 22,025 and 22,026. Sharp, and Sharp and Sons, Ltd. Apparatus for producing watered effects on textile fabrics. Oct. 5.
" 22,370. Pickles and Pickles. Bowls or rollers used in schreinering, calendering, embossing, &c. Oct. 10.
" 22,422. Crumière. Manufacture of artificial silk, horsehair, and the like. [Fr. Appl., Nov. 27, 1905.]* Oct. 10.
[C.S.] 393 (1906). Dyson. Production of designs on pile fabrics. Oct. 17.
" 3549 (1906). Lake (Linkmeyer). Manufacture of artificial silk. Oct. 17.
" 6072 (1906). Friedrich. Manufacture of silk-like threads and of cellulose solutions therefor. Oct. 10.
" 7617 (1906). Johnson (Badische Anilin und Soda Fabrik). Manufacture of discharging pastes for dyed textile fibre. Oct. 10.
" 12,080 (1906). Weiss. Process and composition for dry cleaning fabrics with volatile fat-solvents. Oct. 10.
" 13,788 (1906). Ellis (Chem. Fabr. von Heyden). Manufacture of formaldehyde hydrosulphites and sulphoxylates. Oct. 17.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 21,760. Mewes. Process of liquefying air and winning oxygen. [Fr. Appl., Oct. 3, 1905.]* Oct. 2.
" 21,767. Simm and Simm. Production of zinc oxide. Oct. 3.
" 21,960. Bambridge. Production of sodium sulphide. Oct. 5.
" 22,031. Boult (Urbasch). *See under* XI.
" 22,036. Johnson (Badische Anilin und Soda Fabrik). Manufacture of ammonia and formic acid from cyanides. Oct. 5.
" 22,039. Johnson (Badische Anilin und Soda Fabrik). Manufacture of barium cyanide. Oct. 5.
" 22,327. McTear. Manufacture of salt. Oct. 9.
" 22,525. Johnson (Badische Anilin und Soda Fabrik). Manufacture of stable hydrosulphite.* Oct. 11.
" 22,907. Tobernicz. Manufacture of alkali cyanides. Oct. 12.
" 22,955. City of Bradford, Wyld, and Shepherd. Apparatus for the manufacture of sulphuric and other acids. Oct. 13.
[C.S.] 5437 (1906). Hay. Manufacture of common salt by evaporating brine. Oct. 10.
" 12,208 (1906). Joubert. Manufacture of oxygen [illegible]. Oct. 17.
" 12,807 (1906). Rossler. Production of oxide of [illegible] by means of magnesia. Oct. 17.
" 13,035 (1906). [illegible] Oxygen generators. Oct. 17.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 21,721. Gyperyuk. Manufacture of [illegible] glass. Oct. 2.
[C.S.] 26,595 (1905). Thompson. Utilisation of [illegible] sand or "burgy" from glass works. Oct. 17.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 21,667. British Thomson-Houston Co. (General Electric Co.). Treatment of refractory materials and apparatus therefor. Oct. 1.
" 22,390. Gramiccia. Artificial conglomerates for building purposes.* Oct. 10.
" 22,425. Cowper-Coles. Manufacture of cement. Oct. 10.
" 22,426. Cowper-Coles. Manufacture of cement. Oct. 10.
" 22,487. Watson. Insulating material [illegible] resistance of damp. Oct. 11.
[C.S.] 20,070 (1905). Thom. Artificial stone [illegible]
" 20,153 (1905). Parkes. Burning bricks [illegible] therefor. Oct. 10.
" 20,646 (1905). Sutcliffe and Speakman. *See under* I.
" 6681 (1906). McWhirter. Apparatus for heating, steaming, and chemically treating wood, &c., and for drying such goods. Oct. 10.

X.—METALLURGY.

[A.] 7277A. Betts. Making aluminium. [U.S. Appl., April 1, 1906.]* Oct. 3.
" 21,672. Sulman. Separation of zinc from ores or compounds. Oct. 1.
" 21,770. Simpson and Bourcoud. Production of iron. Oct. 2.
" 21,811. Bradley. Depositing metals or alloys on other metal alloys or fabrics without the aid of a bath. Oct. 3.
" 21,864. Carson. *See under* XIIIA.
" 21,876. Ruthenburg. Methods and apparatus for reducing ores. Oct. 3.
" 21,947. Elmore. *See under* I.
" 22,065. Crowe. Open-hearth steel plant. Oct. 5.
" 22,032. Brandenburg. Extraction of tin from tin ores, ashes, waste, residues, &c.* Oct. 5.
" 22,033. Brandenburg. Extraction of iron from iron-containing tin products such as residues, slags, ashes, scrap, &c.* Oct. 5.
" 22,162. McIvor and Fradd. Extraction of tin from ore or oxide. Oct. 8.
" 22,166. Carrick and Pattinson. Smelting sulphide ores.* Oct. 8.
" 22,174. Hyatt and Bamber. Manufacture of iron and steel. Oct. 8.
" 22,264. James (Hobson). Gold alloy.* Oct. 9.
" 22,491. Bloxam (Siemens und Halske A.-G.). Production of homogeneous masses of tantalum or other difficultly fusible metal.* Oct. 11.
" 22,534. Sulman. Separation of zinc from its ores or compounds. Oct. 11.
" 22,663. Nicklin. Process for recovering iron from the slag of puddling furnaces. Oct. 13.
[C.S.] 17,561 (1905). Boult (Sutton and Steele). Dry concentration of ores. Oct. 10.
" 17,653 (1905). Boult (Sutton and Steele). Dry electric separators. Oct. 10.
" 20,004 (1905). Goldschmidt and Weil. Manufacture of metals according to the aluminio-thermic process. Oct. 10.
" 20,390 (1905). Bousfield (Mackay and Bousfield). Treatment of sulphide ores. Oct. 17.
" 24,672 (1905). Tucker. Extraction of metals from their ores. Oct. 17.
" 24,714 (1905). Sulman, Picard, and Ballot. Ore concentration. Oct. 10.
" 6666 (1906). Goldschmidt. Aluminium process. Oct. 10.

[C.S.] 3089 (1906). Jensen (Maemeche). Mixtures for heating by reduction of metallic compounds. Oct. 17.
„ 6569 (1906). Townsend. Reduction of sulphide ores or compounds. Oct. 17.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 21,769. Schoop. Graphite carbon electrodes for electrical bleaching apparatus. Oct. 2.
„ 22,000. Sokal, Bloomfield, Wolf and Wolff. Storage batteries.* Oct. 5.
„ 22,002. Wheatley and Lark. Deposition of metallic alloys by electrolysis. Oct. 5.
„ 22,031. Boult (Urbasch). Electrolytic manufacture of peroxide of hydrogen. Oct. 5.

Meeting held at University on Wednesday, October 10, 1906.

DR. JAMES T. CONROY IN THE CHAIR.

THE GRADUAL DETERIORATION OF NITRO-CELLULOSE ON STORAGE.

BY OSWALD SILBERRAD, PH.D., AND ROBERT CROSBIE FARMER, D.SC., PH.D.

Among the characteristics which distinguish the nitric ester explosives from the true nitro-compounds, one of the most important, from a practical point of view, is the tendency to decompose gradually but continuously, even at ordinary temperatures. Although numerous qualitative observations have been made as to the characteristics which accompany the deterioration of nitrocellulose, very few quantitative data have hitherto been published. Indications of the gradual deterioration are given by Abel (Phil. Trans., 1867, 157, 181); Thomas (Zeits. angew. Chem., 1898, 1027); Spica (Atti. del Reale 1st Veneto, 1899, 58, 289), and others; but no systematic examination of the progress of the decomposition has hitherto been published. In the present work, the explosives have been systematically examined and analysed at intervals during storage. The influence of temperature has been examined by a series of trials in which the powders were stored at different temperatures in large thermostats; the effect of moisture has also received full consideration. In order to approximate as closely as possible to the conditions of storage in powder magazines, large quantities of the explosives have been taken (in many instances several hundred kilogrammes). From the results of the trials, the following conclusions have been drawn:—

(1) *Physical alterations on storage.*—In general, an external examination of the powder gives very little information as to the degree of deterioration which it has undergone; it is only when the decomposition has proceeded to an extreme pitch, that any marked alterations in the physical properties are observable, although, in Russia, the usual stability tests are supplemented by an external examination of the powders (course of Naval Artillery, 1901–02).

The most marked characteristics of deterioration in nitrocellulose powders are the following:—

(a) *Odour.*—Nitric peroxide is liberated during the decomposition, and permeates the nitrocellulose; thus highly deteriorated powders smell strongly of this product. In cases where ether-alcohol has been used as the gelatinising solvent, an odour of ethyl nitrite is frequently also noticeable.

(b) *Action on packing materials.*—The nitric peroxide and free acids formed on storage also attack the silk cloth wrappers of the cartridges very considerably, weakening the fibres of the cloth and bleaching any colouring matter. Similarly, oiled paper is considerably attacked, whilst if india-rubber sheeting be used as a packing material, the sulphur present becomes oxidised to sulphuric acid, and thus accelerates the decomposition.

For this reason, the use of rubber sheeting should be avoided. The shellac of the primers attached to the cartridges was gradually bleached and ultimately disintegrated.

(c) *Appearance.*—When stored, according as the powder has been heated to a more or less considerable degree, the only alterations that appear are a slight change in colour, usually towards brown, and the powder loses its comparatively glossy and pitted, and shows a striated appearance. In cases of extreme deterioration, the colour darkens greatly, and sometimes becomes almost black. Where the decomposition takes place in a moist atmosphere, the hygroscopic gives rise to deliquescent acid products. Hence, the surface tends to become sticky, and water is taken up with considerable avidity. If the decomposition proceeds far enough, the interior of the sticks becomes filled with a soft, semi-crystalline core, consisting chiefly of oxalic acid. The surface of the nitrocellulose loses its explosive properties to some extent, and in extreme cases the sticks burn with great difficulty, and leave an inner and outer annulus of unburnt substance. This occurs also, to some extent, in a dry atmosphere, but is chiefly noticeable in the presence of moisture. The black powder in the primers of the cartridges gradually disintegrates with production of a fine brown powder, which partially cakes together.

2. *Effect of storage upon chemical analysis.*—A review of the analytical data shows that the deterioration is accompanied by the following alterations:—

(a) *Loss of weight.*—A gradual but continuous loss of weight occurs on storage; this has generally been assumed to be mainly due to the gradual volatilisation of the gelatinising solvents. The results show, however, that the percentage of volatile matter does not in any case decrease materially, and thus the loss of weight must be due to the decomposition of the nitric esters. This is fully confirmed by measurements of the velocity of gas evolution, to be published shortly by the authors.

(b) *Loss of nitrogen.*—A decrease in the percentage of nitrogen always occurs on long storage. This indicates the breaking down of the nitric groups, with formation of oxides of nitrogen, which partially escape, and partially act catalytically upon the remaining nitrocellulose.

(c) "*Soluble*" *and* "*insoluble*" *nitrocelluloses.*—The percentage of matter soluble in ether-alcohol tends to increase, and the insoluble nitrocellulose to decrease. This has erroneously been taken as implying that the insoluble cellulose nitrates break down first, leaving the soluble cellulose nitrates intact. In reality, the two decompose simultaneously, but the tendency is to form compounds which are soluble in ether-alcohol, possibly nitric esters of polyhydroxy acids. These will appear in the analytical results as "soluble in ether-alcohol." The increase in the percentage of soluble nitrocellulose on heating has been confirmed by Bergmann and Junk (Zeits. angew. Chem., 1904, 1075).

(d) *Substances insoluble in acetone.*—The acetone residue shows a slight tendency to increase. This does not indicate a reconversion of nitrocellulose to cellulose, but is to be traced to the formation of insoluble decomposition products. The increase in the acetone residue when nitrocellulose is heated, has been shown by Sy (J. Amer. Chem. Soc., 1903, 25, 568).

(e) *Aqueous extract.*—This forms a valuable guide to the degree of deterioration of nitrocelluloses. The majority of the decomposition products are readily soluble in water (Silberrad and Farmer, Chem. Soc. Trans., 1906, 89, 1168), and thus the water-soluble matter increases on storage. Attempts to estimate the extracted products volumetrically proved unsatisfactory. Potassium permanganate, chromic acid, cuprammonium tartrate, and iodine were reduced by the solution, but gave no satisfactory end points. Titrations with baryta water, using phenolphthalein as indicator, were somewhat more satisfactory.

The residues obtained on evaporating the aqueous extract were, for the most part, insoluble in acetone and in ether.

(f) *Heat test.*—As is well known, the heat test falls as the decomposition proceeds, and in extreme cases the colouration of the test paper appears almost on mixing even in the cold. This is the earliest to appear of all the products than to any decomposition which [illegible]

3. *Examination of the decomposition products.*—Since the oxides and [illegible]

react detrimentally upon the remaining nitrocellulose, the deterioration is auto-catalytically accelerated. This is best illustrated by a comparison of the percentages of nitrogen found at intervals during storage. The following table is extracted from the large scale trials recorded in Table I.

Decrease in percentage of nitrogen in nitrocellulose on storage.

Nitrocellulose powder, diam. 8·75 mm., stored in a dry atmosphere.

Temp. of magazine.	Percentage of nitrogen (calculated on dried substance).				
	unheated.	4½ mths.	9 mths.	10½ mths.	18 mths.
35° C.	13·22	12·88	12·18	12·10	11·77
54·4° C.	13·32	12·17	—	11·78	10·66
60° C.	13·32	12·24	11·81	10·32	—

The oven trials (Tables VIII. to XXV.) show a similar acceleration, though in a number of instances the total decomposition is too slight to give any distinct indication of this. The following list shows the loss of nitrogen during the first and second periods of three months respectively for the powders which underwent sufficient deterioration to affect the analytical results to a marked extent.

Decrease in percentage of nitrogen in nitrocellulose.

Propellant.	Alteration in percentage of nitrogen.			
	Trial at 60° C. in a dry atmosphere.		Trial at 49° C. in a wet atmosphere.	
	First 3 mths.	Second 3 mths.	First 3 mths.	Second 3 mths.

4. *Influence of moisture.*—The trials have shown very conclusively that the humidity of the atmosphere largely determines both the velocity and the nature of the decomposition. At any given temperature, the velocity of deterioration is much greater in a moist atmosphere than in absence of water, the reason being, obviously, that the hydrolytic decomposition of the nitric esters requires the presence of water.

As mentioned above, the physical characteristics of the powder differ very strongly, according as the deterioration has taken place in a wet or a dry atmosphere. The hydrolytic form of decomposition is characterised by the formation of deliquescent hydroxy acids, which render the nitrocellulose more difficult to ignite, and, for this reason, hydrolysis does not readily lead to spontaneous ignition. The nitrous acid formed causes the heat test to fall considerably when a slight hydrolysis occurs, and in such cases the heat test may cause a powder to be condemned, whilst it is still in a perfectly stable condition. Results of firing trials are given in the practical part, to show that the heat test may fall to a very low point, whilst the ballistics are still unaffected. Even when the ballistics commence to suffer, there is little or no liability to spontaneous ignition, and it is thought that in a saturated atmosphere a powder would ultimately lose its explosive properties, without ever having passed through a dangerously unstable condition. Nevertheless, all possible steps should be taken to minimise the amount of hydrolysis which occurs, for this form of decomposition is so rapid that it tends greatly to reduce the serviceable life of the powder.

5. *Influence of temperature.*—The climatic trials at different temperatures show that the decomposition takes place very much more rapidly when the temperature is raised, even by a few degrees. Experiments at higher temperatures indicate that the velocity is approximately doubled by a rise of temperature of 5° C. This points to the necessity of carrying out stability tests very much more frequently in a hot than in a temperate climate. Thus, a powder stored at 40° C. (104° F.) should be tested 16 times as frequently as one stored at 20° C. (68° F.), to ensure an equal degree of safety. Powders manufactured with modern precautions may be regarded as almost indefinitely stable at temperatures below 15° C.

Experimental.

Method of storage.—In order to store such quantities of nitrocellulose powder as would adequately represent the conditions which occur in a magazine, it was necessary to provide chambers of considerable size, whose temperature could be maintained for long periods at a given point. The magazines were situated in an isolated position, and were surrounded by earth mounds, which screened them from each other and from the steam-generating station. Each magazine consisted of a zinc-lined inner chamber, surrounded with a suitable thickness of non-conducting material. This chamber was enclosed in a corrugated iron building, large enough to allow of a passage round the inner chamber. The inside clear dimensions of the inner chamber were as follows: Length, 2·4 m.; breadth, 1·4 m.; height, 1·8 m. One of these magazines, which was required to hold exceptionally large quantities of powder, was 2 m. instead of 1·4 m. in breadth. The chambers had small double plate-glass windows in line with the windows through the outer building, for the purpose of making thermometric observations with the help of a telescope. The refrigerating chamber (temperature, —18° C.) was of the same internal dimensions as the heating chambers, but had thicker non-conducting walls (12 in. thick of flake charcoal). The heating was carried out by means of steam, circulating through coils of pipe. In most cases, the trials were carried out in a dry atmosphere, but in some of the trials, the atmosphere was kept saturated with moisture, by placing the heating coils in a tank of water, and also by blowing part of the steam direct into the magazine.

Regulation of temperature.—The accurate regulation of the temperature in chambers of such a size as the above presented considerable difficulties. After a number of modifications, the method eventually adopted was to control the flow of steam by means of a valve and electro-magnet. The valve, which was placed on a by-pass, was normally open to such an extent as to admit rather more steam than was necessary to retain the temperature at the required point. When the current was allowed to pass through the electro-magnet, the lever which actuated the valve was raised, and the flow of steam was interrupted in the by-pass, and only that passing through the main pipe admitted; this was adjusted so that it was not quite sufficient to maintain the desired temperature alone. The current was regulated by means of a contact thermometer with a spiral built placed inside the climatic magazine. The mercury thread of the thermometer did not, however, form a part of the main circuit which controlled the electro-magnet, as it was considered undesirable to allow a current of such strength to flow through a fine column of mercury. For this reason, a current of [illegible] was passed through the thermometer and [illegible] which, in its turn, controlled the circuit of the [illegible]

In this way the passage of the steam was at once interrupted when the temperature rose above the desired limit. By means of the two clamping screws at the ends of the boiler, the valve could be regulated, so that, when open, the amount of steam allowed to pass was just greatly in excess of the required quantity, and, when closed, the apparatus did not come in absolute contact with the electric magnet.

The temperatures were recorded at intervals of half an hour throughout the trials, and varied only about ±1° C. from the mean temperature.

Fluctuations in composition of nitrocellulose.—Nitrocellulose, being a colloidal mixture of various nitric esters of cellulose, is liable to fluctuations of composition, and these are not wholly removed by the prolonged incorporation of the gelatinised mass. Since this has an important bearing upon the analytical results of climatic trials, experiments were first carried out to ascertain to what extent the different sticks varied in composition, and whether differences could be detected in different parts of the same stick.

A tubular nitrocellulose of diameter 8·75 mm. was chosen for these experiments. Sticks differing as widely as possible in appearance were chosen for analysis, and duplicate analyses were carried out with samples taken from different ends of the same stick (under the headings (1) and (2) in the following table).

Method of sampling.—A bundle of the powder sticks, as taken from the store of the consignment, [illegible] the latter was made by tying together a number of sticks. For the analysis of the collected powder, the bundle was sawn across, near the end, so as to give enough powder for the complete analysis, and the remainder was returned in the magazine, together with the bulk of the powder. At the expiration of stated periods, the bundle was removed and sawn across as before, so that the samples taken before and after storage were made up of discs of equal lengths of a considerable number of different sticks, and were strictly comparable with one another.

Analytical Results.

(*A*) *Large scale experiments.*—The analytical data given in Tables I. to VII. were obtained by stoving large quantities of nitrocellulose powders in climatic magazines as described above. The results have all been calculated to show the composition of the ashless powder, since, as is well known, traces of metal are unavoidably introduced into the powder during grinding.

The volatile matter was estimated after grinding and allowing the sample to reach an approximately constant weight under atmospheric conditions, and is used to correct the analytical results. The nitrogen determinations were carried out as usual by Lunge's method. The volatile matter was estimated by heating to 99° C. for 24 hours. The aqueous extract was determined by treating the ground powder with boiling water, in a Soxhlet extractor, for 1 hour, evaporating the aqueous solution, and drying the residue to constant weight at 80° C. Each figure given is the mean of two closely agreeing results.

Variability in composition of gelatinised nitrocellulose.

——	Per cent. in sample.						Calculated on dried substance.					
	Light stick.		Medium stick.		Dark stick.		Light stick.		Medium stick.		Dark stick.	
	(1)	(2)	(1)	(2)	(1)	(2)	(1)	(2)	(1)	(2)	(1)	(2)
Insoluble in ether-alcohol	7·82	7·72	8·64	8·30	12·80	13·10	8·05	7·93	8·91	8·44	12·89	13·21
Soluble in ether-alcohol	89·00	89·25	89·29	89·71	83·89	83·86	91·58	91·68	92·09	91·25	86·13	86·32
Insoluble in acetone	0·36	0·38	0·22	0·29	0·56	0·52	0·37	0·39	0·23	0·31	0·58	0·54
Volatile matter	2·82	2·65	2·85	2·80	2·75	2·70	—	—	—	—	—	—
	100·00	100·00	100·00	100·00	100·00	100·00	100·00	100·00	100·00	100·00	100·00	100·00
Nitrogen	11·98	12·05	11·92	11·86	11·79	11·80	12·34	12·33	12·40	12·46	12·23	12·28
Ash	1·02	0·87	0·60	0·72	0·78	0·78	1·05	0·89	0·62	0·75	0·79	0·81

From these analytical data it is seen that although the opposite ends of each stick are almost identical in composition, the different sticks show considerable variations. This will give rise to fluctuations in the analytical results, unless the sampling of the powder is systematically carried out. The following procedure was eventually found to be the most satisfactory, and appears to exclude practically all possibility of error.

(*B*) *Climatic trials in air ovens.*—On carefully comparing the foregoing results with those obtained with smaller quantities of powder, it is seen that the conditions of storage can, in most cases, be sufficiently well represented by trials carried out with quantities of about 100 grms. in boxes, designed to correspond with the mode of packing used for large quantities. The boxes are stored in air ovens, maintained at accurately regulated temperatures.

In the present trials, the conditions chosen were :—

(1) 60° C. (140° F.) in a dry atmosphere.

(2) 49° C. (120° F.) in a moist atmosphere.

The temperatures were retained at the required points by Scheibler's regulators, and were read at frequent intervals to ensure constancy. The fluctuations seldom exceeded ± 1° C.

The sampling was carried out exactly as described above, the powders being tied into bundles, which were sawn across to obtain representative samples. The bundles were weighed before and after the heating. In order to eliminate errors in weight due to the mechanical deposition of moisture in the wet trials, the bundles of powder from these trials were untied and the sticks dried for 24 hours at 38° C. (100° F.) in a dry atmosphere before weighing.

Strips of litmus paper were enclosed with the powders in the boxes, and were examined and replaced after each three months.

TABLE VIII.—*Nitrocellulose powder. No. 53.*

Tubular sticks, gelatinised, external diameter, 7·06 mm.; internal diameter, 2·98 mm. Colour, light chocolate brown, fairly homogeneous.

	Unheated.	3 months at 60° C. (140° F.) dry.	6 months at 60° C. (140° F.) dry.	3 months at 49° C. (120° F.) wet.	6 months at 49° C. (120° F.) wet.

ENGLISH PATENTS.

Atomising liquids; Centrifugal fans or machines for ——. P. Kestner, Lille, France. Eng. Pat. 20,698, Oct. 12, 1905.

THE improvement claimed consists in constructing the casing, in which the atomising fan works, of such large dimensions internally, that the mist produced by the fan is not thrown violently against the walls of the casing and condensed to liquid, but has room to fall slowly to the bottom of the casing. By this arrangement the atomised liquid remains for a comparatively long period in intimate contact with the air or gas, so that very complete humidification or washing is attained.—W.H.C.

Kilns; Vertical ——. E. Schmatolla, Berlin. Eng. Pat. 21,116, Oct. 18, 1905.

SEE Addition of Sept. 26, 1905, to Fr. Pat. 352,549 of 1905; this J., 1906, 267.—T. F. B.

FRENCH PATENTS.

Vapours [Water, alcohol, ether, &c.]; Separation of ——, *soluble in sulphuric acid and mixed with air.* H. de Chardonnet. Fr. Pat. 361,648, July 26, 1905.

THE mixture of air and vapour is driven by fans, capable of producing a pressure equal to from 80 to 120 mm. of water, through a series of leaden chambers or towers in which a mist of sulphuric acid is produced by suitable atomisers. The towers are provided with coils through which water or steam is circulated to produce any desired temperature. The towers are arranged in series, in the first of which water only is absorbed by the mist of sulphuric acid, and in the last only the alcohol or ether. From the liquid condensing in the last chamber, the alcohol or ether is recovered by distillation.—W. H. C.

Multiple effect evaporator; Process for causing the liquid to trickle down the tubes in a ——. F. J. L. E. Lancelle. Fr. Pat. 365,945, May 5, 1906.

IN ordinary evaporators the liquid is introduced below the lower tube-plate, and rises up the wide central tube to a level slightly above the upper tube-plate; the tubes are consequently always full of liquid, and the bubbles of vapour are generated against the pressure of this liquid. According to the specification, the liquid is introduced through an injector placed at the lower end of the central tube. The liquid is projected vertically upwards, and falls as a spray upon the upper ends of the evaporator tubes, down which it trickles. The level of the liquid is not allowed to rise above the lower tube-plate, and the vapour is generated much more easily, as the tubes contain no column of liquid the pressure of which has to be overcome.—W. H. C.

Heating and evaporating liquids by means of steam Apparatus for ——. D. B. Morison. Fr. Pat. 366,413 May 19, 1906. Under Int. Conv., May 24, 1905.

SEE Eng. Pat. 10,817 of 1905; this J., 1906, 462.—T.F.B

Kinetic energy of a moving fluid; Process for transforming the chemical energy of a combustible into the ——, *and apparatus therefor.* A. Vogt. Fr. Pat. 366,301 May 15, 1906.

SEE Eng. Pat. 3607 of 1905; this J., 1906, 746.—T. F. B

Drying or converting liquids into the solid state; Process and apparatus for ——. J. Kunick. Fr. Pat. 366,286 May 16, 1906. Under Int. Conv., March 3, 1906.

THE cylinder, on the surface of which the material is to be dried, is encased in a shell, and a current of air is forced through the annular space between the two. The rapid current of air enables the evaporation to be conducted at a low temperature, so that the solids are not overheated and injured. Several cylinders may be employed. If the drying is conducted at temperatures in the neighbourhood of 40° C., the current of air must be previously heated, but at higher temperatures this is not necessary.—W. H. C.

Dryer. Aktiebolaget-Separator. Fr. Pat. 366,546, May 23, 1906.

THE claim is for a centrifugal drying machine in which the perforations of the drum are made conical, and are provided with brushes or scrapers to remove any solid which may accumulate in and stop up the orifices.—W.H.C.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 921.)

Oxygen, carbon dioxide, and steam; Rates of action of —— *on carbon.* P. Farup. VII., page 983.

ENGLISH PATENTS.

Agglomerates, paint material, fuel briquettes, and the like; Manufacture of ——. R. A. Le Maitre, Ixelles-Brussels, Belgium. Eng. Pat. 15,818, Aug. 2, 1905.

SEE Fr. Pat. 350,951 of 1905; this J., 1906, 10.—T. F. B.

Briquettes; Manufacture of weather-proof —— *by means of binding materials soluble in water.* R. Bock, Smichow, Austria. Eng. Pat. 23,902, Nov. 20, 1905.

SEE Addition of Nov. 18, 1905, to Fr. Pat. 325,708 of 1902; this J., 1906, 466.—T. F. B.

Petroleum; Manufacture of solidified —— *for use as fuel.* J. M. A. Stillesen, Brooklyn, U.S.A. Eng. Pat. 38, Jan. 1, 1906.

SEE U.S. Pat. 809,998 of 1906; this J., 1906, 140.—T. F. B.

[*Suction*] *Gas-producing plants.* H. J. Grice, Acocks Green, Worcester. Eng. Pat. 19,410, Sept. 26, 1905.

Two suction gas producers, each of which can supply all the gas required by the engine, are connected through suitable valves to a common washing and cleaning plant. Whilst one producer is in use, the other is held in reserve. When it is necessary to shut off the first, to clean out the clinker, the valve controlling the reserve producer is opened slightly, and the generation of gas is allowed to proceed in it until it is in full working condition, whereupon the valve is opened fully, and the first producer is shut off. —H. B.

Gas manufacture. R. G. Shadbolt, Grantham, Lincs., and C. B. Tully, London. Eng. Pat. 21,124, Oct. 18, 1905.

The process of blending producer gas and coal gas, described in Eng. Pat. 16,955 of 1905 (this J., 1906, 917), is modified by causing the producer gas, before it mixes with the coal gas, to pass through a mass of incandescent coke or the like, whereby the carbon dioxide in the producer gas is to a large extent reduced to the monoxide. In carrying out the process in a bench of horizontal retorts, one of the retorts may be employed as a reducing retort, being connected at the rear end, by a vertical channel, with the top of the gas generator, and at the front with an ascension pipe leading to the hydraulic main. By this arrangement the producer gas is led through incandescent coke, contained in the retort, on its way to the hydraulic main.—H. B.

[*Suction*] *Producer gas generators.* T. W. S. Hutchins, Manchester, and J. B. Wilkie, Liverpool. Eng. Pat. 22,974, Nov. 9, 1905.

The vertical pipe conveying the hot gas from the top of the producer to the foot of the scrubber is wound externally with a helix of fibrous material, on to which water is fed; and the pipe is surrounded by a wider pipe, open at the top, and communicating at the bottom with the space beneath the fire in the producer. When the producer is in action, the air supply is drawn down the latter pipe, and carries with it the steam given off by the wet fibrous material. The producer is closed below the fire grate, by a horizontal plate on to which water is fed, and the steam generated from it likewise mingles with the air supply.—H. B.

Gas retort; Introduction of steam or gas into a ——. G. A. Heckert, Munich, Germany. Eng. Pat. 25,045, Dec. 2, 1905.

See Fr. Pat. 360,032 of 1905; this J., 1906, 406.—H. B.

Producer gas plants. Tangyes, Ltd., and J. H. Pitt, Smethwick, Staffs. Eng. Pat. 26,763, Dec. 22, 1905.

The improvements claimed consist essentially in the combination, with the gas plant, of a heated chamber, on to the walls of which the gas-charged water from the drain-box of the scrubber of the gas plant is delivered, in order to expel evil-smelling gases from the water, and render it fit for re-use. In applying the method to a suction gas plant in connection with a gas engine, the water from the scrubber is delivered into a tank, pumped thence through the water jacket of the engine cylinder, delivered hot in the form of a spray on to the outside of the exhaust-gas box, and, thus purified, is led into a tank and again delivered into the scrubber. The carbon monoxide, &c., expelled from the water, may either be allowed to escape along with the exhaust gases, or may be kept apart from the latter for use. This system enables the usual circulating tanks for the engine to be dispensed with. —H. B.

Gasifying raw combustible materials; Method of and apparatus for ——. P. Hoering and W. Wieland, Berlin. Eng. Pat. 2245, Jan. 29, 1906.

Gas is generated from combustible materials, such as peat and the like, containing large quantities of water, by first carbonising them in a vertical still or retort, and then producing gas from the coked substance in a generator situated beneath the retort, and separated from the latter by a valve, the generator being fed periodically from the retort. The retort is heated externally either by the hot producer gases, or by the combustion of the distillation gases. To prevent damage to the separating valve by the heat of the coke in the retort, the latter is provided centrally with a vertical pipe, open at both ends, and extending from near the top to near the separating valve; the steam generated in the upper parts of the fuel is thus led down, and discharged into the coke near the valve, cooling the coke, and then mingling with the distillation gases. Alternatively, the valve, or the portion of the retort casing near it, may be water-cooled, the steam generated being passed into the apparatus. The gases and steam liberated in the retort may be led down into the generator either directly, or after having been burned in fire-tubes surrounding the retort.—H. B.

Suction gas producers. F. Bauke, Berlin. Eng. Pat. 8276, April 5, 1906.

See Fr. Pat. 363,348 of 1906; this J., 1906, 842.—T. F. B.

Gas retorts. T. Jerratsch, Schwerin, Germany. Eng. Pat. 8433, April 7, 1906.

Gas generators; Suction ——. F. Bauke, Berlin. Eng. Pat. 8778, April 11, 1906.

See Fr. Pat. 365,364 of 1906; this J., 1906, 920.—T. F. B.

Protective gas; Production of non-oxidising ——, *for use in conjunction with petroleum and other combustible liquids.* C. Martini and H. Hüneke, Hanover. Eng. Pat. 10,948, May 10, 1906. Under Int. Conv., May 15, 1905.

See Addition of Oct. 31, 1905, to Fr. Pat. 337,733 of 1903; this J., 1906, 363.—T. F. B.

[*Air-*] *Carburetting process, and apparatus therefor.* F. Grünewald, Schöneberg, Germany. Eng. Pat. 12,127, May 24, 1906.

Air is carburetted at ordinary atmospheric temperatures by passing it through a rotating drum containing a network of intersecting bars, which are kept constantly wetted with a thin film of "viscous liquid fuel" (*i.e.*, liquid hydrocarbon having a sp. gr. exceeding 0·7).—H. B.

Carburetting apparatus. F. Grünewald, Schöneberg, Germany. Eng. Pat. 12,128, May 24, 1906.

"Non-absorbent balls, preferably spherical and of such a size that the interstices between them are not filled by the liquid," are used as filling material for the carburetting chamber of an apparatus for carburetting air by means of liquid hydrocarbon.—H. B.

Incandescing bodies for electric incandescent lamps; Manufacture of ——. A. Just and F. Hanaman, Budapest, H. Landesberger and I. Salzmann, Vienna, and Verein. Electricitats A.-G., Budapest, Hungary. Eng. Pats. 20,175 and 20,175A, Oct. 5, 1905.

See Fr. Pat. 358,272 of 1905; this J., 1906, 213.—T. F. B.

French Patents.

Washer for coal and other materials. Heyl and Patterson, Incorporated. Fr. Pat. 364,640, Jan. 23, 1906.

The washer consists essentially of an oscillating table, the foundation of which consists of a series of transverse laths, alternately fixed and movable. The laths placed at one end of the table are close together, and have only one side inclined, whilst those at the other end are further apart, with the intervals gradually diminishing between them, and have both their faces inclined. The finest impurities are removed at the former end of the table. —A. G. L.

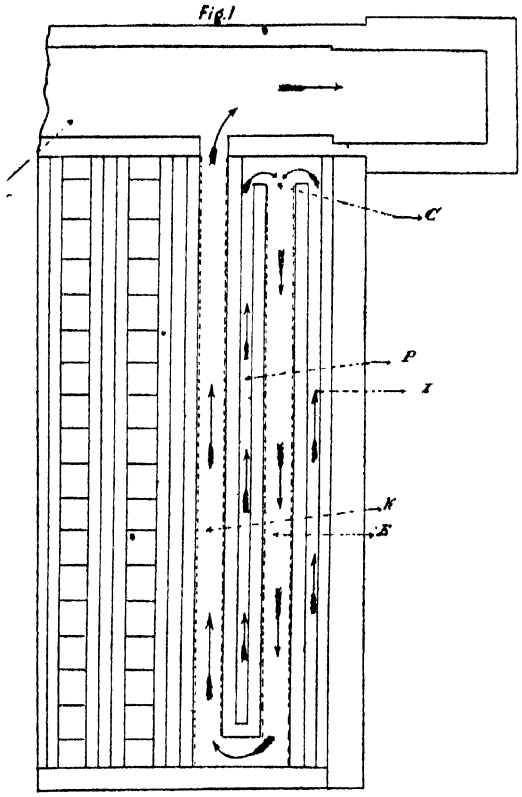
Fuel; Method of preparing solid ——. S. Börlin. Fr. Pat. 365,762, April 30, 1906.

Lumps of calcined magnesium carbonate are mixed in

petroleum until they have absorbed as much as they will take up (about three times their own weight), and, after draining, they are ready for use as fire-lighters, &c.—C. S.

Coke ovens; System of high-temperature ——. E. Ippolito. Fr. Pat. 365,868, March 7, 1906. Under Int. Conv., March 9, 1905.

Fig. 1



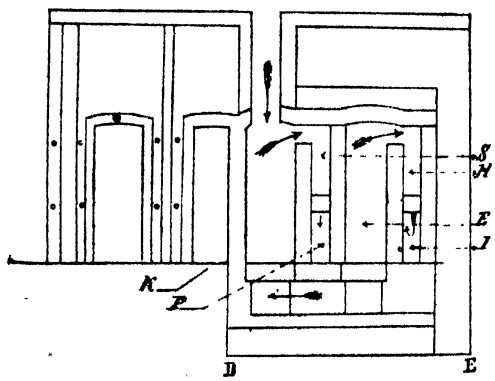


Fig. 2

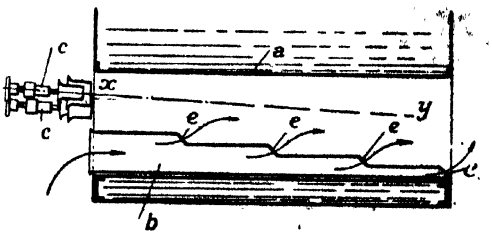


THE system is shown in the accompanying illustrations, of which Fig. 1 is a plan and Fig. 2 is an end view, partly in section. All the gases issuing from the oven, E, heat the horizontal channels, H and I, and then heat the sole of the oven on issuing from the horizontal channel at C. In a similar manner the gases from the oven, K, traverse the horizontal channels, S and P, and unite with the gases from E at C, whence they pass under the sole of both E and K, to escape into the collector, W, leading to the chimney stack; that is to say, the gases from the two ovens are concentrated in order to heat the soles of both. The horizontal channels may be replaced by vertical ones.—C. S.

Coke oven. O. A. Gobbe. Fr. Pat. 366,002, May 8, 1906. Under Int. Conv., May 15, 1905.

THE principle involved is the utilisation of the gases distilled from the coal for transmitting the calories liberated by the red hot coke to the coal under distillation, the requisite heat for keeping the apparatus at work being furnished by burning a little coke, coke-oven gas, or other gas. The oven consists of a number of ovens joined in pairs, and communicating by means of conduits fitted with regulating bells and an aspirator. Each oven is provided with a bell for admitting air to the upper part of the oven, two charging orifices, and a conduit leading to a tank for the surplus gas. Conduits with regulator bells are provided under the sole of the ovens, for the admission of air under the sole.—C. S.

Boiler fire-box for liquid or gaseous fuels. A. and S. Seigle. Fr. Pat. 361,597, July 1, 1905.

THE ordinary fittings being removed from the flue, *a*, the liquid or gaseous fuel is injected by two or more injectors, *c*, *c*, in the direction indicated by the line, *x*, *y*. At the bottom of the flue, *a*, is placed an air chamber or casing, *b*, the upper surface of which is stepped as shown, and provided with rows of openings, *e*, in each of the steps. The air necessary for combustion is drawn through these openings by the natural draught in the direction indicated by the arrows, so that the gaseous fuel burns progressively along the whole length of the flue.—W. H. C.

Heat energy; Apparatus for the production of —— *in a closed receiver.* M. Castelnau. Fr. Pat. 365,509, April 23, 1906.

THE apparatus consists of a strong closed receiver, into which a combustible gas or liquid (*e.g.*, petrol) and a gaseous or liquid supporter of combustion (*e.g.*, compressed or liquefied air or oxygen) are forced simultaneously by means of a system of three pumps. A certain proportion of water is also injected into the receiver. The combustible mixture is ignited electrically or otherwise, thereby producing a mixture, at high pressure, of steam and the products of combustion, which is led off from the receiver to drive a motor.—H. B.

Smoke: Process of washing and laying ——. J. F. P. Kestner. Fr. Pat. 365,453, April 21, 1906. Under Int. Conv., May 5, 1905.

SEE Eng. Pat. 9549 of 1905; this J., 1906, 555.—T. F. B.

Gas containing suspended dust or smoke; Process for the rapid washing of ——. J. F. P. Kestner. Fr. Pat. 365,452, April 21, 1906. Under Int. Conv., May 5, 1905.

SEE Eng. Pat. 9548 of 1905; this J., 1906, 464.—T. F. B.

Gaseous mixture containing hydrogen and methane; Manufacture of a ——. P. Sabatier. Fr. Pat. 361,616, July 7, 1905.

IN the patentee's earlier French patents (this J., 1905, 1164), are described processes for producing a mixture

of hydrogen and methane by (1) decomposing water-gas in presence of reduced nickel, iron, or cobalt, at 300°—500° C., and (2) causing steam to react upon the carbonised metals at 400°—500° C. According to the present invention the two operations are conducted simultaneously; a mixture of steam and water-gas is led over the reduced metals at 400°—500°, and from the product any useless constituents, such as carbon dioxide, may be removed if desired. Instead of water-gas, any gas containing carbon monoxide, with or without hydrogen, may be employed; *e.g.*, producer gas, blast-furnace gas.—H. B.

Gas producer. G. Viarmé. Sixth Addition, dated March 31, 1906, to Fr. Pat. 309,432, March 27, 1901.

An annular steam generator, situated at the base of a suction gas producer, is provided with lateral holes for escape of the steam, and with a hole in the bottom through which the excess of water may drop into the enclosing ash-box. An outlet pipe at the base of the ash-box allows the water to flow out into a receiver, whereby the workman is enabled to judge of the sufficiency or otherwise of the water supply. In order that the suction of the producer may not disturb the free flow of the water from the ash-box, the wall of the latter is perforated at a point above the water outlet; the water thus flows out at a pressure equal to, or but little inferior to, that of the atmosphere. —H. B

Gaseous mixtures; Centrifugal separator for ——. E. Mazza. Fr. Pat. 365,534, April 24, 1906. Under Int. Conv., April 29, 1905.

See Eng. Pat. 7421 of 1906, this J., 1906, 841.—T.F.B.

Sulphuretted hydrogen; Process for removing —— from gas. E. Burschell. Fr. Pat. 366,047, May 9, 1906.

To remove sulphuretted hydrogen from gas in the wet way, the gas is washed with an alkaline solution of ferric salt, obtained, for example, by dissolving 3 parts of potassium tartrate in 100 parts of water, and adding an excess of ferric hydroxide containing caustic potash or potassium carbonate. The ferric hydroxide is at first dissolved partly by the tartrate; as the dissolved portion is precipitated in the form of sulphide by the sulphuretted hydrogen in the gas, fresh quantities pass into solution, the dissolving and precipitation proceeding as long as any ferric hydroxide remains. The sulphide of iron produced is then oxidised in the air, with liberation of sulphur and formation of ferric hydroxide, soluble in the liquid as at the start.—H. B.

Sulphur and cyanides from spent oxide, &c.; Process and apparatus for the extraction of ——. J. J. M. Bécigneul. Third Addition, dated April 7, 1906, to Fr. Pat. 345,071, July 23, 1904. VII., page 985.

Calcium carbide; Method of making ——. H. L. Hartenstein. Fr. Pat. 365,800, May 1, 1906.

See U.S. Pat. 819,219 of 1906; this J., 1906, 544.—T.F.B.

Calcium carbide and method for its manufacture. H. L. Hartenstein. Fr. Pat. 365,801, May 1, 1906.

See U.S. Pat. 819,220 of 1906; this J., 1906, 544.—T.F.B.

Calcium carbide; Method of protecting ——. H. L. Hartenstein. Fr. Pat. 365,802, May 1, 1906.

See U.S. Pat. 819,221 of 1906; this J., 1906, 544.—T.F.B.

Calcium carbide; Process and apparatus for making ——. H. L. Hartenstein. Fr. Pat. 365,803, May 1, 1906.

See U.S. Pat. 819,222 of 1906; this J., 1906, 544.—T.F.B.

Filaments for incandescence lamps; Manufacture of ——. J. Canello. Fr. Pat. 361,602, July 3, 1905.

See U.S. Pat. 829,568 of 1906; this J., 1906, 919.—T.F.B.

Luminous bodies for electric incandescence lamps; Process for making ——. H. Kuzel. First Addition, dated July 26, 1905, to Fr. Pat. 359,025, Jan. 9, 1905.

See Eng. Pat. 15,462 of 1905; this J., 1906, 307.—T.F.B.

Filaments for incandescence lamps. A. Just and F. Hanaman. Third Addition, dated Feb. 14, 1906, to Fr. Pat. 347,661, Nov. 4, 1904 (this J., 1905, 431 and 1220, and 1906, 843).

Tungsten filaments obtained as in the original patent are amorphous, and therefore break readily. By incorporating with the tungsten a small proportion of certain more readily fusible metals, such as chromium, vanadium, tantalum, thorium, &c., the filament during the final heating fuses so far as to assume a crystalline character, with interlacing needles, whereby its fragility is overcome. The process consists in forming into filaments a mixture of finely pulverised tungsten, a small proportion of one of the metals mentioned, and an organic binder; carbonising the mixture; eliminating the carbon by heating the filament in a mixture of steam and hydrogen; and finally heating the filament electrically to a high temperature. —H. B.

Filaments for incandescence lamps. A. Just and F. Hanaman. Fourth Addition, dated Feb. 19, 1906, to Fr. Pat. 347,661, Nov. 4, 1904 (see preceding abstract).

A filament of carbon, or of metal, or of a mixture of carbon and metal, is coated with tungsten or molybdenum by heating it electrically in a low-pressure atmosphere of hydrogen containing a gaseous compound of the metal. A pressure of 200 mm. of mercury is suitable. It is stated that at a low pressure the deposition of the metal occur more uniformly, and the deposit has a crystalline form. Several filaments may be mounted in series, and submitted simultaneously to the process.—H. B.

Conductor; Electric ——, especially suitable for incandescence lamps. Parker Clark Electric Co. Fr. Pat. 366,236, May 14, 1906.

See U.S. Pat. 821,017 of 1906; this J., 1906, 594.—T.F.B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 921.)

Carbonisation of wood by superheated steam. F. Elfström. Teknisk Tidskrift, 1905, General Section, 289—291. Proc. Inst. Civil Eng., 1906, **164**, 60—61.

Superheated steam is introduced directly into the first member of a row of retorts; the steam, together with the gases evolved from the wood, then passes to the next retort, and so on. The greater part of the heat is required for evaporating the moisture contained in the wood, but the steam need not be so highly superheated for this purpose as for the subsequent charring of the wood. The hottest steam is therefore introduced into the retort in which the carbonisation is nearest completion, whilst the fresh wood is charged into the last retort of the series, wherein it is subjected to the action of the steam and gases coming from the other retorts. With ten large retorts connected in series, each of 20—30 cb. m. (about 700—1000 cb. ft.) capacity, carbonisation is completed in 12—20 hours, whilst drawing and charging take 4—5 hours, so that each retort can be worked off once in 24 hours. When carbonisation is complete in a retort, saturated steam is passed in for one hour; this becomes superheated to some extent, and after passing through the superheater, is used for completing the charring in the next retort. Water is next introduced, in small quantities, into the cooling retort, and afterwards, for one hour, a fine spray of water is showered upon the charcoal, which is then ready to be drawn. The mixed steam and gases from the finished retort, on their way to the superheater, are led through boiling water in a covered tank, in which the heavy oils (b. pt. 200°—250° C.) are condensed. It is stated that by working with superheated steam, the yield of oil is increased by about 17 per cent., and the oil is of much better quality, whilst the consumption of fuel does not exceed 15 per cent. of the weight of charcoal obtained; woodman's chips and saw-mill refuse can be used for fuel. —A. S.

"Cracking gas" from Baku crude oil; Examination of ——. C. Engler and L. Rosner. Oesterr. Chem. u. Techn. Zeit., 1906 [9]. Chem. Rev. Fett- u. Harz-Ind., 1906, 13, 144—145.

THE crude oil used for the distillation was brownish-black, very viscous, and had an unpleasant odour. It had a sp. gr. of 0·912 at 15° C., and on distillation in an Engler's flask gave the following results:—Benzine (at 95° to 140° C.), sp. gr. 0·775, 4 per cent.; petroleum (140° to 280° C.), sp. gr. 0·847, 31 per cent.; cracking distillate (at 280° C.), sp. gr. 0·902, 59 per cent.; and loss (gases), 6 per cent. by volume. The cracking process, carried out as far as possible under the same conditions as in practice, gave the following yield:—Cracking distillate, 78; coke, 12; and gas, 10 per cent. On the assumption that the only paraffin hydrocarbons present in the gas were methane and ethane, it was found to have the following composition by volume:—Carbon dioxide, 0·6; unsaturated hydrocarbons, 12·0; oxygen, 1·0; carbon monoxide, 2·2; hydrogen, 8·8; methane, 43·0; ethane, 31·9; and hydrogen sulphide, 0·6 per cent. A comparison of these figures with those of various naturally occurring mineral gases shows a striking agreement, and hence the author infers that the formation of natural gas and of cracking gas is due to analogous processes. The heat of combustion of the gas analysed calculated from its chemical composition is 8400 calories. The author points out that on an average about 10 per cent. by volume of the petroleum residue submitted to the cracking process escapes in the form of gas, and suggests that factories should take steps to utilise this gas.—C. A. M.

Mineral lubricating oils; Chemical constants in the analysis of ——. R. Kissling. Chem.-Zeit., 1906, 30, 932—933.

IN addition to the iodine value and Maumené figure, the author has determined the amount of asphaltum-pitch formed on heating the oils, and terms the result the "resinification number" (*Verharzungszahl*). In making a determination, 50 grms. of the oil are heated in a thermostat for 60 hours in five periods of 12 hours each, at a temperature of 125° to 135° C., the heating being discontinued for 12 hours each night. The oil and the pitch-like residue are then washed with petroleum spirit into a 500 c.c. flask, which is filled to the mark with the same solvent, and allowed to stand for 12 hours. The deposit is then collected on a weighed filter, washed with petroleum spirit, dried, and weighed. The amounts of asphaltum-pitch thus obtained with 21 representative oils ranged from 0·044 per cent. to 3·114 per cent. The iodine values were determined by Wijs' method upon 2 grms. of the oil dissolved in 25 c.c. of carbon tetrachloride, and the Maumené figures by treating 50 c.c. of the oil with 25 c.c. of sulphuric acid (100 per cent. monohydrate) in a well-isolated apparatus devised by the author. The following are typical of the comparative results:—

Oil.	Sp. gr. at 15° C.	Viscosity in Engler's apparatus at 25° C.	Solidification point.	Flashing point.	Ignition point.	Asphaltum pitch.	Iodine value.	Maumené figure.
			° C.	° C.	° C.	per cent.		° C.
American spindle ...	0·870	5·20	0	200	225	0·696	11·05	11·5
Do. refined ...	0·875	5·00	0	200	228	0·144	10·20	10·7
Russian machine ...	0·907	27·0	fluid at—15	215	255	0·250	7·20	8·1
American turbine ..	0·922	16·50	—2	220	267	1·730	10·88	15·1
Machine (? Texas) ..	0·948	13·00	—9	214	260	1·612	9·46	16·4

There was but little parallelism between the numbers in the last three columns, but the agreement between the amounts of asphaltum-pitch and the Maumené figures was closer than between the Maumené figures and iodine values. In the author's opinion but little reliance can be placed upon the iodine number as a constant, and little more upon the Maumené figure. But he considers the resinification number as a useful criterion of an oil. The amount of asphaltum-pitch formed on heating was materially reduced by refining the oil. The nature of the crude oil from which the lubricant was prepared had a considerable influence on this constant, and it would seem that in this respect Pennsylvanian and Russian oils are the best. Four turbine oils examined differed greatly as regards the formation of pitch (0·081 to 2·12 per cent.), whereas there was but little difference in their iodine values and Maumené figures. In practice the four oils behaved approximately in accordance with the indications shown by the resinification number, and the oil yielding 2·12 per cent. also dirtied the machinery through separation of the pitch after the usual lubrication whilst the turbine was not being used.—C. A. M.

Petroleum production of Roumania. Bd. of Trade J., Oct. 4, 1906. [T.R.]

THE production of Roumanian petroleum during the first half of 1906, as compared with the first half of 1905, was as follows:—

	First half, 1905. Metric tons.		First half, 1906. Metric tons.
Production of crude petroleum	272,167	..	404,358
Production of petroleum refineries.....	223,761	..	352,287
Export—			
Crude distilled petroleum	19,904	..	18,387
Lamp oil.....	39,887	..	98,913
Benzine	26,045	..	34,016

FRENCH PATENTS.

Hydrocarbons; Process for the partial dehydrogenation of ——. Soc. Anon. des Combustibles Industriels. Fr. Pat. 365,428, April 19, 1906.

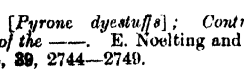
IT is stated that hydrocarbons (tars, tar oils, &c.) can be polymerised or condensed to form other hydrocarbons by passing air, alone or mixed with oxygen, ozone, or some inert gas, through the heated hydrocarbon; the heat produced by the partial oxidation and condensation is said to be sufficient to complete the distillation. The products are similar to those produced by ordinary distillation at a higher temperature. The following is an example of the process: A coal tar of sp. gr. 1·1705, and elementary composition, carbon, 91·07 per cent., hydrogen, 5·36 per cent., is first heated to 105° C., and air is blown in at the rate of about 2 litres per minute per kilo. of tar; the distillation is continued until the temperature has reached 180° C., when a pitch, of the composition, carbon, 91 per cent., hydrogen, 9 per cent., and of sp. gr. 1·22, is obtained. By similarly distilling a mineral oil tar (sp. gr. 0·937), previously heated to 300° C., until the temperature is 375° C., it is stated that the products consist of a series of hydrocarbons of value as lubricants, and a pitch which is well suited to briquetting purposes. —T. F. B.

Ammonia; Extracting —— from gas-liquor. A. Fillunger. Fr. Pat. 365,769, April 30, 1906.

THE gas liquor is heated, preferably in a column apparatus, without addition of lime. The ammonia is collected, and the liquid, freed from all but a minute proportion of combined ammonia (0·05 per cent.), is pumped into a cooling tower, whence it is taken to the scrubber, to be again used in absorbing ammonia from gas. The process is repeated indefinitely, so that one and the same quantity

of gas water circulates continually, and further additions of washing water are unnecessary. Two kinds of distilling columns are shown: one adapted for use when superheated or dry steam is directly employed to drive off the ammonia; and the other, in which indirect heating by ordinary vapour is used, with or without the aid of dry steam.—E. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

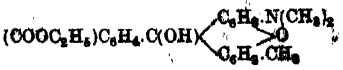


(*Continued from page* 924.)

Azo dyestuffs derived from the pyridine series. R. Baumert. Ber., 1906, **39**, 2971—2976.

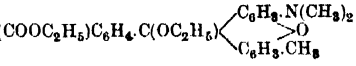
The author has prepared azo dyestuffs containing the pyridine ring by combining the diazo-derivatives of *p*-amino-γ-stilbazol and *p*-amino-α-stilbazol with phenols and amines. *α-Stilbazol-p-azo-β-naphthol hydrochloride*, prepared by combining the diazo-derivative of *p*-amino-α-stilbazol with β-naphthol in alkaline solution, and subsequently acidifying with hydrochloric acid, crystallises from hot alcohol in red-brown leaflets, m.pt. 252—253° C. The dyestuff is slightly soluble in hot water, and its solution dyes silk, wool, cotton, and mordanted cotton red. *γ-Stilbazol-p-azo-β-naphthol hydrochloride* was prepared in a similar manner from *p*-amino-γ-stilbazol. It dyes rather darker shades than the foregoing compound, and melts at 257°—258° C. *α-Stilbazol-p-azoresorcinol* is only slightly soluble in water, and dyes silk and cotton yellowish-brown, wool, and mordanted cotton coffee-brown. *γ-Stilbazol-p-azoresorcinol* gives redder shades than the corresponding α-compound. *Sodium-α-stilbazol-p-azo-β-naphthol sulphonate*, obtained from Schäffer's salt dyes silk, wool, cotton, and mordanted cotton bright red. *Sodium-γ-stilbazol-p-azo-β-naphthol sulphonate* possesses similar properties to the foregoing. *Disodium-α-stilbazol-p-azo-β-naphthol disulphonate*, obtained from R salt, dyes silk, wool, and cotton bluish-red, and mordanted cotton violet. *Disodium-γ-stilbazol-p-azo-β-naphthol disulphonate* has similar dyeing properties, but produces redder shades on mordanted cotton.—J. C. C.

Isorosindone and analogous compounds [*Azine dyestuffs*]; *Constitution of* ——. H. Decker and A. Würsch. Ber., 1906, **39**, 2653—2656.



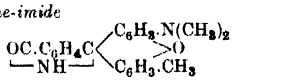
In order to decide between the para- and ortho-quinonoid formulæ for dyestuffs of the azonium class, the authors have studied the action of phenyl-magnesium bromide on isorosindone. If it possessed the para-quinonoid ketonic formula it should, like cyclaminone, yield a tertiary carbinol passing into a phenylated naphthazonium salt on treatment with acids. No such reaction, however, took place, and the conclusion is drawn that isorosindone possesses the ortho-quinonoid formula,

The molecular weight was confirmed by a cryoscopic determination in benzene solution.—J. C. C.



Rhodamines [*Pyrone dyestuffs*]; *Contribution to the knowledge of the* ——. E. Noelting and K. Dziewonski. Ber., 1906, **39**, 2744—2749.

Aporhodamine ethyl ester hydrochloride was obtained by passing dry hydrogen chloride through a boiling solution of the base in absolute ethyl alcohol for 8 hours. It crystallises from boiling water containing a little hydrochloric acid in bright red needles possessing a gold reflex. It is very easily soluble in cold alcohol, and fairly so in cold water. It melts at 95° C., and contains 5 mols. of water of crystallisation, of which four are lost by drying in a vacuum over sulphuric acid, and the remainder by heating to 120° C. By treatment with aqueous alkalis or moist silver oxide, a coloured base appears to be first formed, which gives a yellow solution on extraction with ether. This substance, possibly the *pseudo-carbinol base* of the aporhodamine ester



however, rapidly passes into the hydrolysed aporhodamine base, and appears not to be capable of isolation, owing to its readiness to form the lactone. When, however, the ester hydrochloride is treated with alkalis in cold alcoholic solution, the ester base is formed, the carbinol hydroxyl group becoming at the same time etherified. With ammonia in alcoholic solution, an acid carbinolimide is produced. The aporhodamine ester salt dyes tannin-mordanted cotton yellowish-red. The dyeings are stronger and a little bluer than those of aporhodamine; they are also faster to washing.

Aporhodamine ethyl ester-carbinol ethyl ether

is formed by treating the cold alcoholic solution of the ester hydrochloride with the calculated amount of potassium hydroxide. It separates as a viscid mass, which becomes crystalline after some time. It crystallises from hot alcohol in small, colourless prisms of m.pt. 105° C. It is easily soluble in cold alcohol, ether, benzene, or xylene. The substance dissolves in hot acids, with elimination of alcohol and formation of a coloured salt, identical with the original ester salt.

Aporhodamine-imide

is obtained by treating the aporhodamine ester hydrochloride with ammonia in boiling alcoholic solution. Glistening white prisms of m.pt. 227° C. separate, containing half a mol. of alcohol, which is expelled by heat. The substance dissolves in boiling dilute acids, yielding colourless salts. Saponification experiments with alcoholic potash or concentrated mineral acids were without result. Tetra-ethylrhodamine-silver nitrate and aporhodamine-silver nitrate are also described. (See also this J., 1905, 1296.)—J. C. C.

Indigo; Analysis of ——. C. Rawson. XXIII., page 1009.

Dyestuffs; Recognition and discrimination of artificial organic ——. G. Gulinow. XXIII., page 1007.

English Patents.

Dyestuffs: Manufacture of new azo ——. G. B. Ellis, London. From Chem. Fabr. vorm. Sandoz, Basle, Switzerland. Eng. Pat. 22,738, Nov. 6, 1905.

See Fr. Pat. 359,222 of 1905; this J., 1906, 424.—T. F. B.

Dyestuff; Production of a sulphuretted [*sulphide*] *black* —— E. Vidal, Paris. Eng. Pat. 23,733, Nov. 17, 1905.

A new dyestuff, which is applicable directly to cotton dyeing, is obtained by heating sodium sulphide and sulphur with amino-*o*-cresol or the corresponding nitro or nitroso compound for about 36 hours at a moderate temperature and in presence of water. *Example.*—Boil in an iron vessel with reflux condenser, 100 kilos. of amino-*o*-cresol, 80 kilos. of sodium sulphide, 50 to 80 kilos. of sulphur, and 800 litres of water.—D. B.

Dyestuffs; Manufacture of ortho-oxymonoazo ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Hoechst a/Main, Germany. Eng. Pat. 26,383, Dec. 18, 1905.

See U.S. Pat. 827,468 of 1906; this J., 1906, 922.—T.F.B.

Dyestuffs; Manufacture of new azo ——. Société pour l'Ind. Chim. a Bâle, Basle, Switzerland. Eng. Pat. 12,421, May 28, 1906. Under Int. Conv., May 29, 1905.

See Addition of May 29, 1905, to Fr. Pat. 321,040 of 1902; this J., 1906, 14.—T. F. B.

United States Patent.

Anthracene derivative [dyestuff], and process of making same. M. H. Isler, Mannheim, Germany, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 831,002, Sept. 11, 1906.

New anthracene derivatives are obtained by treating a 4-halogen-1-aminoanthraquinone, substituted in the ortho position to the amino group, *e.g.*, 4-chloro-1-amino-2-methylanthraquinone, with a mixture of nitric and sulphuric acids, and then with phenol. They are obtained in the form of crystals, insoluble in alkalis. After being sulphonated, the products dye wool in blue shades from an acid bath.—A. S.

French Patents.

Indigo; Production of finely divided ——. Badische Anilin und Soda Fabrik. Fr. Pat. 361,589, June 28, 1905.

See Eng. Pat. 12,854 of 1905; this J., 1905, 885.—T.F.B.

1.4-Dihydroxynaphthalene; Production of monoalkylethers of ——, *and mono- and disazo dyestuffs derived therefrom.* Badische Anilin und Soda Fabrik. Fr. Pat. 364,585, March 26, 1906. Under Int. Conv., Sept. 8 and 13, 1905.

See Eng. Pats. 7287 and 7287A of 1906; this J., 1906, 922.—T.F.B.

1.2-Diazonaphtholsulphonic acids and their salts; Production of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 365,919, May 4, 1906. Under Int. Conv., April 14, 1906.

See Eng. Pat. 10,323 of 1906; this J., 1906, 751.—T.F.B.

Dyestuffs; Manufacture of red vat [anthracene] ——. Badische Anilin und Soda Fabr. Fr. Pat. 365,920, May 4, 1906. Under Int. Conv., April 18, 1906.

By condensing a diaminoanthraquinone, especially 1.5-diaminoanthraquinone or α- or β-diaminoanthraquinone, with 2-chloroanthraquinone, new vat dyestuffs are obtained. For example, 20 kilos. of 2-chloroanthraquinone, 10 kilos. of 1.5-diaminoanthraquinone, 15 kilos. of anhydrous sodium acetate, 3 kilos. of cuprous chloride, and 600 kilos. of naphthalene or nitrobenzene are boiled for 15 to 20 hours under a reflux condenser. The new compound has probably the constitution—

$$C_{14}H_7O_2(2)NH(5)C_{14}H_6O_2(1)NH(6)C_{14}H_7O_2,$$

three anthraquinone residues being united by means of two imino groups. It is filtered off, washed with toluene, then with hydrochloric or glacial acetic acid, and finally with water. When treated with strong or fuming sulphuric acid, with or without addition of boric acid, it yields dyestuffs giving greyish-green to Bordeaux-red shades on wool from an acid bath. With an alkaline hyposulphite (hydrosulphite) solution, it forms a yellowish-red vat, in which cotton is dyed in red shades, very fast to alkalis, acids, chlorine, and light.—A. S.

Dyestuffs; Process for the production of polyazo ——. L. Cassella und Co. Fr. Pat. 361,590, June 28, 1905.

See U.S. Pat. 807,119 of 1905; this J., 1906, 65.—T.F.B.

Dyestuffs; Process for the production of trisazo ——. L. Cassella und Co. Fr. Pat. 361,624, July 12, 1905.

See Eng. Pat. 14,787 of 1905; this J., 1906, 368.—T.F.B.

Dyestuffs; Process for the production of polyazo ——. L. Cassella und Co. First Addition, dated July 24, 1905, to Fr. Pat. 361,590, June 28, 1905.

See U.S. Pat. 807,119 of 1905; this J., 1906, 65.—T.F.B.

Dyestuffs; Process for preparing red, deep red to violet, sulphide ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 361,608, July 4, 1905.

See Eng. Pat. 14,543 of 1905; this J., 1906, 260.—T.F.B.

Dyestuffs; Process of making o-hydroxyazoazo ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 361,649, July 26, 1905.

See U.S. Pat. 827,468 of 1906; this J., 1906, 932.—T.F.B.

Dyestuffs: Process for preparing red, deep red to violet, sulphide ——. Farbwerke vorm. Meister, Lucius, und Brüning. First Addition, dated Aug. 5, 1905, to Fr. Pat. 361,608, July 4, 1905.

See Eng. Pat. 14,543 of 1905; this J., 1906, 260.—T.F.B.

Dyestuff suitable for preparing lakes; Process for making an azo ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 366,110, May 11, 1906. Under Int. Conv., July 12, 1905.

Anthranilic acid is diazotised and combined in alkaline solution with 2.6-naphtholsulphonic acid: the resulting dyestuff gives a yellowish-red solution in water, and forms brilliant red lakes with metallic salts, very fast to light.—T. F. B.

Vegetable bodies; Process for the extraction of substances [Dyestuffs, tanning matters, &c.] from ——. J. Clarion. Fr. Pat. 361,656, Aug. 1, 1905.

The process claimed consists in subjecting the vegetable substances, in a finely divided condition, first to maceration with a suitable solvent, and subsequently to pressure in a screw or other form of press, or in a mill. The process is repeated as often as is necessary to ensure complete extraction, and can be arranged so that the materials are treated first with the weak liquor from a previous extraction, and subsequently by weaker liquors or by the pure solvent.—W. H. C.

Dyestuffs; Manufacture of new azo ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 365,582, April 25, 1906. Under Int. Conv., Sept. 30, 1905.

Azo dyestuffs giving yellowish-red to scarlet shades on unmordanted cotton are obtained by combining one molecule of the tetrazo-derivative of the *p-p*-diaminodiphenyl ether of quinol either with two molecules of 2-amino-5-naphthol-7-sulphonic acid or its substitution derivatives, or first with one molecule of this acid or its derivatives and then with one molecule of another suitable compound, or *vice versa*. The *p-p*-diaminodiphenyl ether of quinol, $(NH_2)C_6H_4.O.C_6H_4.O.C_6H_4(NH_2)$, is obtained by treating *p*-chloronitrobenzene with the potassium salt of quinol, and reducing the resulting nitro-derivative.—A. S.

Anthracene derivatives [dyestuffs]; Manufacture of new ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 366,005, May 8, 1906. Under Int. Conv., Sept. 1, 1905.

The new derivatives are obtained by nitrating α-β-dianthraquinonylamine (see Fr. Pat. 357,138 of 1905; this J. 1906, 66), and reducing the resulting nitro-compounds. They form vat dyestuffs dyeing unmordanted cotton in green shades. For example, 20 kilos. of α-β-dianthraquinonylamine are mixed with 110 kilos. of 95 per cent. nitric acid, the temperature not being allowed to rise above 40° C. The mixture is subsequently heated to 60°—70° C.; the resulting brown solution deposits golden-yellow leaflets of the nitro-compound. The latter when heated with phenylhydrazine yields a green dyestuff, giving olive-green shades on cotton when dyed in a vat containing glucose and caustic soda.—A. S.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 926.)

Quinaldine; Dyeing properties of the products of condensation of —— with aldehydes. E. Noelting and E. Witte. Ber., 1906, **39**, 2749—2751.

The authors have investigated the dyeing properties of benzalquinaldine, $C_9H_6N.CH:CH.C_6H_5$, and its deriva-

tives. A 3 per cent. solution of the hydrochloride dyes tannin mordanted cotton intensely yellow; wool and silk are only very slightly coloured. Bulach's *p*-nitrobenzalquinaldine dyes similarly but greener; the *o*-nitrobenzalquinaldine, m. pt. 147° C. (hydrochloride, m. pt. 275° C.) and *m*-nitrobenzalquinaldine, m. pt. 233° C., also dye tannin mordanted cotton yellow, and have scarcely any affinity for wool or silk. The piperonal- and nitropiperonal-derivatives give similar shades. The introduction of the amino-group into benzalquinaldine notably increases the dyeing properties. The condensations were effected by heating equal molecules of the bases and the aldehyde with a little concentrated hydrochloric acid on the water-bath for 10 hours. *p-Dimethylaminobenzalquinaldine* was obtained by heating equimolecular quantities of the components for three-quarters of an hour to 150° C. Pale yellow leaflets were obtained by recrystallisation from alcohol, and brownish-yellow, flat needles from benzene. The compound, which is a strong base, m. pt. 177° C., dissolves to a claret-red solution in dilute acids. It is soluble in alcohol, glacial acetic acid, benzene, &c. A yellow *polyhydrochloride* is precipitated by passing hydrogen chloride through the benzene solution; this becomes red on drying in a vacuum over potassium carbonate. *p-Aminobenzalquinaldine* obtained from *p*-aminobenzaldehyde and quinaldine, or by reduction of the corresponding nitro-compound, is at first colourless, but on drying, becomes bright red, m. pt. 154° C. The *hydrochloride*, m. pt. 273° C., forms red needles; it dyes tannin mordanted cotton red, and wool silk orange. 3:4-Dihydroxybenzalquinaldine described by Nencki is a basic and a mordant dyestuff. The hydrochloride dyes wool, silk, and tannin mordanted cotton orange-red, and the base gives with Scheurer's mordanted cotton strips the following shades: aluminium, brownish-red; iron, dark-brown to black; cerium, thorium, zirconium, yttrium, uranium, chromium, bismuth, and titanium, brown to violet-brown; cobalt, nickel, zinc, and cadmium, a light or Havanna brown. These lakes are fairly fast to soaping. The acetyl derivative of dihydroxybenzalquinaldine crystallises in yellow needles, m. pt. 165° C. It is soluble in alcohol, acetic acid, or chloroform, with difficulty in ether or benzene, insoluble in water. It dyes tannin mordanted cotton yellow, but the compound is not very stable, and the dyeings gradually become orange, approaching the shade of the non-acetylated substance.—J. C. C.

Coal-tar dyestuff lakes; Fastness to light of different ——. E. Valenta. Chem.-Zeit., 1906, **30**, 901—904.

The following is a list of the dyestuffs examined by the author, arranged in order of their fastness to light. *Reds:* Alizarin Red, Pigment Scarlet 3 B and G, Fast Orange O, Permanent Red 6B, Autol Red BGE, Cotton Scarlet extra, Permanent Red 4B, Lake Red P, Autol Red BL, Astazine Red B, Pigment Red G, Pigment Red B, Brilliant Lake Red R, Astazine Red G, Pigment Bordeaux N, Autol Red BLP, Eosine acid ("Eosinsäure") L, Permanent Orange, Pigment Orange R, azo dyestuff from nitranilinesulphonic acid and β-naphthol, Lithol Red GG and R, Brilliant Carmine L, Lake Red C, and Pigment Purple A. *Yellows:* Alizarin Yellow 5G, Pigment Fast Yellow G and R, Pigment Chrome Yellow L, Pigment-Chlorin GG, and Flavazine 3GL. *Blues and violets:* Indanthrene S, Alkali Blue, Oxamine Blue GN, Lanacyl Violet 3B, Oxamine Copper Blue RR, Immedial Pure Blue, Victoria Blue GN, and Acid Violet PW. *Greens:* Light Green SL and Lake Green BW. In the majority of cases the dyestuffs were precipitated with barium and aluminium hydroxides, and in a few instances as calcium and tin lakes. Dyestuffs deficient in salt-forming groups such as Pigment-Chlorin GG, Pigment Chrome Yellow, Pigment Orange, Pigment Red, and Pigment Bordeaux, were mixed with water with or without the addition of salt solutions such as barium or calcium chlorides. Victoria Blue was precipitated with tannin and tartar emetic in the usual manner.—D. B.

Fats from refuse material. A. Löb. XII., page 995.

Turkey-red oils; Analysis of ——. Herbig. XXIII., page 1002.

English Patents.

Textile fabrics; Washing machines for ——. H. Dydynski, Whaley Bridge, Derbyshire. Eng. Pat. 6871, March 22, 1906.

To obviate the destructive action of the beaters in machines for washing textile fabrics, the goods saturated with the cleansing liquid are drawn out of the washing vessel, and acted upon, whilst suspended in a slack state, by beaters rotating in a direction contrary to that in which the material is travelling. The beaters are preferably arranged so that they act on both sides of the fabric, but when two beaters only are used, their striking edges are placed out of line with one another, to divert the direction of the suspended cloth, and prevent undue tension.—D. B.

Cloth or other fabrics; Drying cylinders for ——. F. Farnworth, Ramsbottom, Lancs. Eng. Pat. 20,279, Oct. 7, 1905.

The cylinders are constructed of tinned iron or other suitable metal, and are provided with a rough surface by electrically depositing copper or other suitable metal on the outside face, so that the cloth in drying will adhere to the surface, and in this manner be prevented from shrinking.—D. B.

Formaldehyde-sulphoxylates [*Discharges*]; *Manufacture of* ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Hoechst a/Main, Germany. Eng. Pat. 3222, Feb. 9, 1906.

Ketone-sulphoxylates may be transformed into the more stable formaldehyde-sulphoxylates by treating them with formaldehyde. For instance, to a solution containing 140 parts of acetone-sodium sulphoxylate in 1 litre of water are added, whilst stirring, 75 parts of formaldehyde of 40 per cent. strength. The combination occurs rapidly, and the product may be obtained in a solid form by evaporating in a vacuum, when the acetone distils off.—D. B.

French Patents.

Silk fibres [*Cellulose-coated silk fibres retaining their tenacity when wet*]; *Manufacture of water resisting artificial* ——. Soc. Anon. pour l'Etude Ind. de la Soie Serret. Fr. Pat. 363,949, March 7, 1906.

Fibres, having the same tenacity in the wet as in the dry state, are produced by coating natural silk fibres with cellulose by passing them through a solution of the latter. To protect them against the action of the solvents employed, the silk fibres may be treated with formaldehyde or other compounds having a similar action upon them. The fibres thus coated are spun either together with one another, or with uncoated silk fibres. In the latter case, the uncoated fibres are preferably stretched while being spun or twisted with the coated fibres, so that when the yarns produced are submitted to tension, the strain may be chiefly borne by the uncoated fibres.—E. B.

Cellulose solutions, adapted for use in the manufacture of artificial fibres, resembling in appearance silk; Manufacture of ——, *and of such fibres.* E. W. Friedrich. Fr. Pat. 364,066, March 12, 1906. Under Int. Conv., March 13, 1905.

Basic copper salts in ammoniacal solution have the property of dissolving cellulose, but the solutions produced are not sufficiently concentrated to be applicable to the manufacture of fibres. By substituting for the cellulose, however, certain of its derivatives, namely, oxycellulose, hydrocellulose, hydrated cellulose, or colloidal cellulose, solutions of suitable concentration (containing 10 per cent. or more of the cellulose derivative) may readily be prepared. The best results are obtained with cellulose compounds obtained by subjecting cellulose to the action of either an oxidising agent, caustic soda-lye at 30° B., or an acid, such as sulphuric acid at 50° B.,

and then, after washing, again treating the products with one of these reagents, but a different one from that previously applied. Compared with the cupro-ammoniacal solutions of cellulose hitherto prepared for the same purpose, the solutions of the products in an ammoniacal or alkylaminic solution of a basic copper salt, such as the basic carbonate, sulphate, phosphate, or acetate, have the advantage, it is stated, of remaining unchanged and fit for use in the manufacture of fibres for a relatively long time. Textile fibres are produced from them by the usual methods.—E. B.

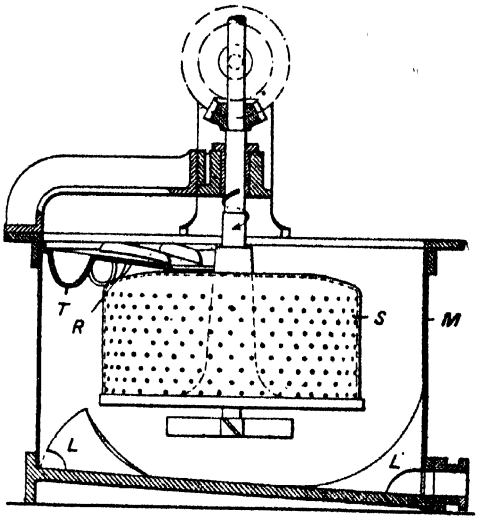
Artificial silk; Machine for spinning ——. E. Mertz. Fr. Pat. 364,912, April 4, 1906.

The pipe which supplies the silk solution under pressure is surrounded by another pipe in which a refrigerating liquid circulates. In one form of apparatus the spinning machine consists of a hollow comb-shaped vessel, which is connected to the supply of solution by a pipe and tap. The tooth portion consists of a number of glass tubes with capillary openings. The spinning apparatus are placed in tanks containing an acid solution in order to give the thread a certain consistence, and these tanks are themselves placed in cooling tanks. The threads from the required number of spinnarets are led through a guide, which, by means of an elliptical arrangement of wheels, is made to move to and fro in front of a revolving bobbin, so as to wind the thread into the shape of a bobbin with conical ends. The winding rollers dip into a suitable washing liquid. Another form of spinning apparatus consists of a tube in the shape of a truncated cone. In this is placed a spindle of the same shape which has several fine longitudinal grooves on it. This spindle is pressed into the truncated portion of the other tube by means of a rubber pad. The solution enters at the lower part, and is forced through the grooves on the spindle, which form capillary openings when the spindle is forced into the outer tube. In another form each capillary opening is furnished with a tap so that any desired number of threads can be spun together. By means of conical driving pulleys the speed of the machine can be altered, and so the fineness of the fibres obtained may be varied.—A. B. S.

Viscose; Process for forming pliable threads, ribbons, bands, &c., from ——. M. Müller. Fr. Pat. 365,776, April 30, 1906. Under Int. Conv., May 1, 1905.

See Eng. Pat. 10,094 of 1906; this J., 1906, 753.—T. F. B.

Cleaning fabrics with benzene or other volatile degreasing agents; Process for ——. E. Weiss. Fr. Pat. 366,547, May 23, 1906.



Textile fabrics are cleaned with benzene, to which is added a saponified solution of oleine or other vegetable or animal fats in alcohol. This solution is prepared by adding a hot mixture of 4 volumes of ammonia of sp. gr. 0·910, and 1 volume of alcohol to 4 volumes of oleine, and heating the whole to boiling. Solutions saponified by caustic soda or potash, and containing the above-mentioned quantity of ammonia, may also be used.
—J. C. C.

Wool, silk, and other fibres; Process for treating by carbonisation rags of ——. S. Roberts. Fr. Pat. 365,880, April 21, 1906.

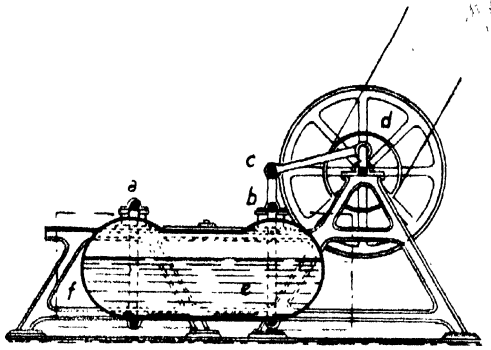
See Eng. Pat. 4593 of 1905; this J., 1905, 1225.—T. F. B.

Turbine [Dyeing apparatus] for circulating liquors in a dye-vessel of large capacity. Gebrueder Wansleben and L. Hwass. Fr. Pat. 364,281, March 15, 1906. Under Int. Conv., Nov. 3, 1905.

The textile materials to be dyed are placed in the perforated rotary cage, S (see figure), of a centrifugal machine. The motion of the cage, acting in conjunction with the resistance offered by the sides of the cage, and aided by the directing action of a number of curved blades, L, attached to the bottom of the vessel, causes the dye-liquor present in the latter to rise up against the sides, and to overflow into perforated pockets, T, arranged for its reception in the cover, R, surmounting the apparatus. Thence the liquor flows into the cage, S, from which it is

projected, through the textile materials being dyed, into the outer vessel, M. As, in dyeing by this method, a relatively large volume of dye-liquor, namely, about 15 times that of the materials to be dyed, is needed, it is expedient to employ vessels of large size. These are made by increasing the height rather than the diameter of the smaller-sized centrifugal machines.—E. B.

Fibrous materials in hanks; Machine for dyeing ——. C. Corron. Fr. Pat. 364,692, March 29, 1906.



This machine consists of a series of dye-vats placed side by side. The framework supporting the hank reels can be lifted out of each tank by means of a hydraulic piston placed centrally in the tank, and, for convenience in moving the hanks from one vat to another, sliding pieces fitted with rollers are fixed to each end of the framework. These are pushed under the frame when the latter is in the vat, but can be pulled out when the framework is lifted, and the frame can then be run along on these rollers upon a pair of rails placed above the vats.
—A. B. S.

Artificial silk or other textile material wound on bobbins; Machine for washing or dyeing ——. E. Mertz. Fr. Pat. 364,913, April 4, 1906.

The bobbins carrying the material are supported at each end by bearings fixed to two endless vertical chains. These chains can be revolved intermittently by means of gearing connected with a lever and cam arrangement. The edges of the bobbin reels are in contact with a vertical plate faced with caoutchouc, and placed on one side of them. The reels press against this, and are thus caused to revolve on their axes during the upward motion. The liquid to be applied is forced over the uppermost bobbin through a perforated pipe, and is caught in a vessel placed beneath the bobbin. This vessel is also perforated, and the liquid thus falls on to the next lower bobbin, and so on to the bottom. The material is thus submitted to a liquid becoming more and more pure as it rises to the top of the machine. The bobbins are removed at the top, and fresh ones inserted at the lower part of the endless chain.—A. B. S.

Textile fibres; Arrangement for treating [Bleaching, dyeing, &c.] —— with liquids. R. Hausdorf. Fr. Pat. 366,250, May 15, 1906.

Textile fibres are treated with liquids in the various operations of washing, boiling, bleaching, and dyeing in a rectangular vessel with curved and perforated ends. This is fixed to a bar, *e*, which is connected by hanging bars with the shafts, *a* and *b*, and can be brought into

vertical and horizontal motion by means of the crank, *d*. The vessel is fixed in a bath containing the liquid, and the mode of agitation ensures the contact of the liquid with every portion of the fabrics.—J. C. C.

Hosiery; Machine for printing the ("circulaire") tubular fabrics of ——. Soc. Anon. de Blanchiment, Teinture, Impressions, et Apprets de St. Julien. Fr. Pat. 364,806, March 31, 1906.

To keep the material at a constant width during the printing of hosiery in the form of a tube, a stretching apparatus, previously adjusted to the correct width, is placed within the tube, and the whole is set on two supporting rollers placed close together. The end of the stretcher nearest the printing rollers takes the form of two thin plates, which pass between the two supporting rollers, nearly to the point where the printing cylinder and the press-roll come in contact, so that the material in passing from the stretching device to the printing cylinder has no opportunity of contracting or shrinking.—A. B. S.

Felts and other textile fabrics; Process for rendering —— waterproof. C. A. McKerrow, W. B. Hart, and W. S. Mallandain. Fr. Pat. 366,518, May 23, 1906.

Felts and similar fabrics are rendered waterproof by immersing them in a solution of glue or gelatin, and fixing the latter by the aid of bichromates, alums, ferric salts, sulphate of zinc or magnesium, and other similar salts. The material after immersion in the glue bath may be also exposed to the action of formaldehyde vapour, whereby a similar effect is produced.—J. C. C.

Drying apparatus [for fabrics]; Vacuum ——. E. Gessner. Fr. Pat. 365,656, April 23, 1906.

See Eng. Pat. 7928 of 1906; this J., 1906, 845.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(*Continued from page* 881.)

English Patent.

Dyeing, cleaning, washing, and the like [Feathers]; Apparatus for ——. J. J. Brossard. London. Eng. Pat. 16,902, Aug. 21, 1905.

In this invention, which is especially applicable to the machine described in Eng. Pat. 18,194 of 1904 (this J., 1905, 1011), the casings, within which the dyeing or cleaning is effected, are corrugated on their internal periphery, and provided with perforations passing through the convex portions of the corrugations, the object being to prevent the deterioration to delicate goods caused by the rotary motion of the casings. For the treatment of goods requiring a great amount of washing, a longitudinal partition or rubbing board is provided within the casings, which is perforated through the convex portions of the corrugations.—D. B.

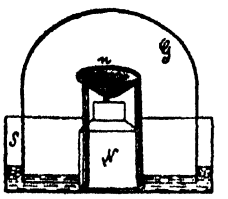
French Patents.

Dyeing hair; Process for ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 361,635, July 19, 1905.

See Eng. Pat. 14,212 of 1905; this J., 1906, 532.—T. F. B.

Dyeing hair, fur, and other articles; Process for ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 366,427, May 19, 1906.

Pyrogallolsulphonic acid is used instead of pyrogallol for dyeing hair and fur. The process is carried out in either neutral or slightly alkaline solution. It is advantageous to add a mild oxidising agent, such as hydrogen peroxide, to the solution, and dark shades of brown may be obtained by treating the hair, &c., after having been freed from excess of pyrogallolsulphonic acid, with solutions of iron salts.—J. C. C.



Leather and skins; Process for printing in colour on ——. A. Dubois. Fr. Pat. 365,361, April 18, 1906.

Leather and skins are printed by any suitable apparatus with alcoholic solutions of the requisite dyestuff, *e.g.*, 50 grms. of Magenta dissolved in 1 litre of alcohol. It is stated that the colours do not spread beyond the limits of the design, either during or after printing, and that they are quite fast to water and light. The printed leather is preferably coated with varnish. Any kind of undressed leather is suitable for this process, either dry or chromed. —T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 929.)

Sodium hydroxide solution; Explosion in Küster's apparatus for the preparation of pure ——. A. Harpf and H. Fleissner. Z. chem. Apparatenkunde, 1906, 1, 534—535. Chem. Centr., 1906, 2, 994. (See this J., 1904, 1027.)

The apparatus used by the authors is shown in the accompanying figure, wherein *n* is a funnel-shaped dish of nickel gauze of very narrow mesh, which is supported on a tripod above the nickel bottle, N. The glass-bell, G, rests on glass rods in the glass dish, S, which is filled with water to above the lower end of G. Pieces of sodium are placed in *n*, and a strong solution of sodium hydroxide falls slowly into the bottle, N. After being in use for four days, during which time large gas bubbles escaped from the bell from time to time, a violent explosion occurred on the fifth day. The authors suggest that the explosion was one of oxy-hydrogen gas, the ignition of the gas being effected by the heat of formation of the sodium hydroxide. When the bell was replaced by a glass bottle, the neck of which was fitted with a cork, through which passed a tube for the removal of the oxy-hydrogen gas as it formed, no explosions occurred on using the apparatus.—A. S.

Sodium hydroxide solution; Explosion in Küster's apparatus for the preparation of pure ——. F. W. Küster. Z. chem. Apparatenkunde, 1906, 2, 535—536. Chem. Centr., 1906, 2, 994—995.

The author points out that the explosion described by Harpf and Fleissner (see preceding abstract) could not have been due to oxy-hydrogen gas, since at the time when it occurred there could have been only pure hydrogen

in the apparatus. At the ordinary temperature, sodium does not become notably warm in an atmosphere of water-vapour, and local rise of temperature is prevented by the rapid heat conduction throughout the mass of the metal. Two explosions were observed by the author when water was dropped very slowly, and with cooling, upon pieces of bright sodium in an atmosphere of pure hydrogen. Explosions do not occur when the metallic sodium deliquesces in a moist atmosphere without any appreciable rise of temperature, but are caused, even with the well-cooled metal, if overheating occurs at any point, *e.g.*, by contact with a drop of liquid water. The apparatus used by Harpf and Fleissner differs in one important point from that described by the author. In the author's apparatus, the sodium is held in a funnel of nickel gauze of the usual shape with an angle of 60° at the apex. The sodium hydroxide solution formed flows to the apex, and drops therefrom into the bottle below. The greasy impurities of the sodium remain adhering to the walls of the funnel, and do not hinder the dropping of the solution from the apex of the funnel. The pieces of sodium cannot move down to the apex of the funnel. Harpf and Fleissner, on the other hand, use instead of a funnel, a dish of narrow-mesh nickel gauze. After the greasy impurities separate out from the sodium, it is quite possible for a few drops of sodium hydroxide solution to collect on the bottom of the dish; these would be gradually diluted by condensation of water, and might cause the explosion.—A. S.

Barium and calcium carbonates; Behaviour of —— at high temperatures. H. E. Boeke. Z. anorg. Chem., 1906, **50**, 244—248.

FINKELSTEIN has recently stated (Ber., 1906, **39**, 1585; this J., 1906, 534) that barium carbonate does not melt at 1350° C., whereas Le Chatelier had given its melting point as 795° C. (Bull. Soc. Chim., 1887, **47**, 300.) The author shows that these conflicting statements are due to the fact that the two authors worked under different conditions. When heated in an open crucible, barium carbonate loses carbon dioxide, and then melts at about 900° C., but when heated in a current of carbon dioxide, fusion does not take place even at 1380° C. It appears that barium carbonate undergoes some kind of transformation at 811° C., since when heated in an atmosphere of carbon dioxide, a marked diminution in the rate at which the temperature rises is observed.

When crystals of aragonite (sp. gr. 2·943) are slowly heated in an electric "microscope-furnace," they become opaque at 470° C.; after cooling, the crystals are found in their original form, being thus artificial pseudomorphs of calcite after aragonite. The transformation temperature varies with the rate of heating; at 445° C. aragonite is converted completely into calcite in one hour, whilst Mügge found that the transformation proceeds slowly even at 410° C. On heating powdered calcium carbonate under a pressure of 30 atmospheres of carbon dioxide, it dissociates partly at 1400°—1450° C., but does not fuse; the residue contained 68 per cent. of calcium carbonate and 32 per cent. of lime.—A. S.

Zinc carbonate and precipitated cadmium carbonate; Knowledge of precipitated, basic ——. M. Kohn. Z. anorg. Chem., 1906, **50**, 315—317.

FRESHLY-PRECIPITATED cadmium carbonate will also completely precipitate cold solutions of ferric salts, but cold solutions of chromium nitrate, uranyl nitrate, and aluminium nitrate, only to a very slight extent.—A. S.

Lead oxide; Different modifications of ——. R. Ruer. Z. anorg. Chem., 1906, **50**, 265—275.

THE author has investigated the two differently-coloured modifications of lead oxide. A specimen of lead oxide, purchased as "chemically pure," had a brownish-yellow colour; after being heated to between 520° and 620° C. (corr.) it acquired a light yellow colour, which it retained on cooling. On rubbing the light yellow oxide, even with the exercise of only a moderate pressure, the brownish-yellow colour returned, but the light yellow colour was not affected by a hydrostatic pressure of up to 3200 atmospheres. The brownish-yellow oxide does not owe its colour to the presence of a higher oxide, for large, light yellow, transparent crystals of pure lead oxide, when pressed with a glass rod in an atmosphere of hydrogen, acquired a reddish colour. The author is of the opinion that the ordinary brownish-yellow oxide is transformed between 520° and 620° C. into the light yellow oxide, which is unstable at the ordinary temperature, but which appears stable on account of the extremely low rate of transformation into the darker coloured modification. On rubbing, accompanied by pressure, the strains produced cause an acceleration of the rate of transformation, and the brownish-yellow oxide, stable at the ordinary temperature, is slowly formed. The red lead oxide prepared according to Geuther's directions (this J., 1884, 179) behaves, in general, similarly to the brownish-yellow oxide described above, but is not so readily converted into the light yellow modification on heating. The light yellow oxide is about twice as soluble in water as Geuther's red oxide—about $1{\cdot}03\times10^{-4}$: $0{\cdot}56\times10^{-4}$ grm. equivalents per litre at 22° C.—A. S.

Chromates of mercury, bismuth, and lead. A. J. Cox. Z. anorg. Chem., 1906, **50**, 226—243.

THE author has made use of the phase rule in an investigation of the chromates of mercury, bismuth, and lead. For example, in the systems under consideration, the components will be the oxide of the metal, chromium trioxide, and water. If two chromates are present, there will be four phases—chromates, solution, and vapour, and therefore according to the phase rule, only one of the three conditions—temperature, pressure, and concentration—can be altered without disturbing the equilibrium. By working at constant temperature, the only possible displacement of the equilibrium on altering the concentration is by the disappearance of one of the chromates, after which the concentration of the solution will alter with the dilution. In other words, if, on diluting, the concentration of the solution remains constant this is due to the presence of two compounds in the solid phase, the relative proportions of which alter, whereas if the concentration of the solution changes on dilution, the solid phase must consist of one definite compound. By working in this manner the existence of the following chromates was proved, and the compounds were isolated: Mercuric chromates, $HgCr_2O_7$, $HgCrO_4$ and $3HgO_4CrO_3$; lead chromates, $PbCr_2O_7$ and $PbCrO_4$; bismuth chromates, $Bi_2O_3,4CrO_3$ and $Bi_2O_3,2CrO_3$. These salts possess definite hydrolytic dissociation pressures, *i.e.*, they can only exist if the solution contains some free acid, the minimum amount for the several salts being as follows:—$HgCr_2O_7$, 10·46; $HgCrO_4$, 0·46; $PbCr_2O_7$, 6·87; $PbCrO_4$, 0·00002; $Bi_2O_3,4CrO_3$, 7·80; and $Bi_2O_3,2CrO_3$, 0·00001 grm. mol. of chromic acid per litre at 25° C.—A. S.

Stannic sulphate; Compounds of —— with the sulphates of the alkaline-earth metals and of lead. R. F. Weinland and H. Kühl. Ber., 1906, **39**, 2951—2953.

WHEN sulphuric acid solutions of stannic sulphate and calcium, strontium, barium, or lead sulphate are mixed and concentrated by evaporation till the liquid fumes, transparent cubic crystals separate, having the composition (for the calcium salt), $Sn(SO_4)_2$; $CaSO_4$, $3H_2O$. The water appears to be constitutional, as it can only be driven off at temperatures which decompose the salt. The crystals can be washed with acetone, but are decomposed by boiling with water.—J. T. D.

Carbon; Rates of action of oxygen, carbon dioxide, and steam on ——. P. Farup. Z. anorg. Chem., 1906, **50**, 276—296.

THE author determined the rates of action, under similar conditions, of oxygen, carbon dioxide, and steam on carbon. It was found that at about 850°C. the velocity of the reaction is about the same with carbon dioxide as with steam. With oxygen the same velocity is attained at about 450° C. The temperature-coefficients of the reactions were determined, and from the value obtained for the reaction of oxygen with carbon, the velocity of this reaction at 850° was estimated by extrapolation, and found to be 8×10^6 times as great as that of the reactions of

carbon with carbon dioxide and steam, respectively. The results obtained by Nernst and Wartenburg for the dissociation of carbon dioxide and steam at high temperatures (Nachr. der K. Ges. Wissen. zu Göttingen, Mathemat.-physik. Klasse, 1905, Heft 1.) show that pure oxygen at atmospheric pressure and 850° C. has a concentration about $0{\cdot}7 \times 10^6$ times as great as in the gases mentioned at the same temperature and pressure. There appears, therefore, to be a certain relation between the oxygen concentration and the reaction-velocity in the three reactions studied. The author discusses the nature of this relation, but is unable to supply a satisfactory explanation.—A. S.

Fluorine; Action of —— on chlorine, and a new mode of formation of hypochlorous acid. P. Lebeau. Compt. rend., 1906, **143**, 425—427.

FLUORINE and chlorine do not combine directly. Liquid chlorine dissolves fluorine, but when the chlorine is frozen, the fluorine is evolved. In presence of water, fluorine oxidises chlorine, with production of hypochlorous acid. —J. T. D.

Metal acid anhydrides; Action of liquefied ammonia on ——. A. Rosenheim and F. Jacobsohn. XXIV., page 1010.

Phosphoric acid; Quantitative volatilisation of —— from its salts. P. Jannasch and E. Heimann. XXIII., page 1007.

Salt purification in Utah. Mining World, Sept. 8, 1906. [T.R.]

IN the evaporation and subsequent treatment of salt water from the Great Salt lake in Utah, the brine is evaporated by solar heat. The refining is carried on by the drying method, which depends upon heating the salt and driving off the magnesium salts in a fine pulverulent condition by a current of air. The refining process as practised near Salt Air, Utah, is a continuous one, the salt being led to a rotating cylinder about 30 ft. long by 6 ft. in diameter, in the inner part of which is fixed an iron cylinder, about 12 or 16 ins. in diameter, charged with superheated steam. An exhaust fan carries off the water vapour, and the fine dust of magnesium chloride and magnesium sulphate. The salt thus treated is not entirely purified, as the magnesium salts are not entirely removed. The salt for table use has to be treated by a second and third grinding, sifting, and blowing. In 1905, Utah produced 177,342 barrels of salt, valued at $135,465. The output of the whole country was 25,966,122 barrels, valued at $6,095,922.

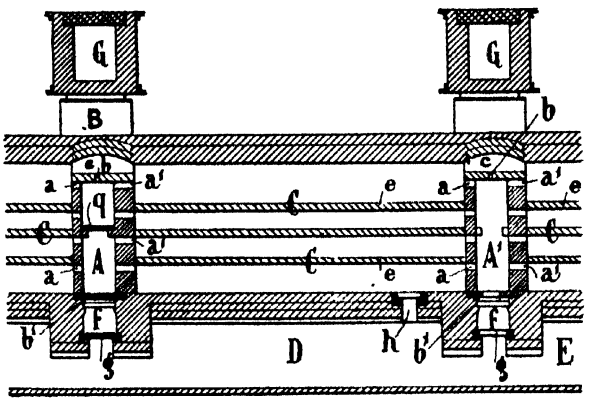
Alkali Works Regulation Act, 1906. [T.R.]

CERTAIN chemical works not hitherto liable to registration are now required to be registered, and are subject to inspection by the Local Government Board's inspectors. In order to ascertain what works throughout England and Wales have thus become subject to registration, a circular letter has been sent by the Local Government Board to the town clerks of boroughs and clerks of district councils asking to be supplied with information so far as regards works carried on within the limits of the district. These include smelting, gas-liquor, nitric acid, chlorine, hydrochloric acid, sulphide, alkali waste, lead deposit, sulphocyanide, picric acid, paraffin oil, bisulphite, tar, zinc, and chemical manure works.

ENGLISH PATENTS.

Cyanogen compounds and by-products; Production of —— from humus. W. F. Cooper, Watford, Herts. Eng. Pat. 2047, Jan. 26, 1906.

HUMUS, such as peat, farmyard or stable manure, or the product obtained by boiling certain carbohydrates with acid, is treated with nitric acid. Hydrocyanic acid is stated to be evolved, together with some nitrous fumes, on distillation. The gases are collected, and treated in any convenient manner for the separation of impurities, and for the production of the desired cyanide compound. The residue left after distillation is stated to form a by-product, valuable as a manure.—E. S.



Copper solutions; Purification of ammoniacal ——. A. Lecœur, Rouen, France. Eng. Pat. 8910, April 12, 1906.

SEE Fr. Pat. 362,986 of 1906; this J., 1906, 808.—T. F. B.

FRENCH PATENTS.

Oven for calcining alumina at a high temperature, and generally applicable for calcining light pulverulent materials. Soc. Electro-Métall. Franç. Fr. Pat. 364,736, March 29 1906.

A SERIES of ovens, C, divided into chambers by horizontal partitions, *c*, on which the alumina to be calcined is placed in thin layers, are separated by combustion-chambers, A, A^1. The furnaces are arranged in a double row, back to back, separated by a division wall in which several separate charging-shoots for each bed are arranged, and the fronts are provided with doors for observing and withdrawing the material. The gaseous fuel enters from one of the mains, G, by the conduit, B, into the cross channels, *c* and *f*, from which it enters the combustion-chamber, A, by the ports, *b* and b^1, and burns in the air which enters by the ports, *a*. The products of combustion pass through

the ports, a^1, into the chamber, C, over the material on the shelves, and into the next combustion-chamber, A^1, by the ports, *a*. The combustion-chambers have passages, *f*, closed by the dampers, *g*, leading into the flue, D, which communicates with the chimney flue, E. They are also provided with tiles, *q*, to adjust the distribution of the hot gases to the ovens. The ovens are worked in series; the gas and air enter and burn in the first combustion-chamber, whose damper, *g*, is closed, pass over the material in the first oven, C, through the next combustion-chamber, and so on to the last of the series, from which they enter the flue, D, either through the ports, *f* or *h*. The principle of the ovens is that the alumina or other material, spread out in thin layers, remains stationary, and the zone of combustion is progressively moved forward as the contents of each chamber become completely calcined.—W. H. C.

Alumina; Furnace for calcining ——. A. Lambert Fr. Pat. 365,744, April 28, 1906.

THE furnace adopted is stated to be on the principle of Hoffmann's furnace, in which chambers containing successive shelves in stages, on which the alumina to be calcined is thinly spread, and heated from above and from below, are arranged in such manner that the gases may circulate throughout. Through openings in the walls that separate the chambers, heated gases are admitted in such quantity as not to disturb the powdery charge,

these openings communicating with vertical channels leading to pipes conveying the gases of combustion. Dampers are so placed as to give control throughout to the direction and force of the currents of gases. It is claimed that the arrangements made permit of the complete utilisation of the heat of the gases of combustion, and of the heat of the calcined alumina.—E. S.

Carbonic acid; Production of —— [from gases of combustion]. G. A. Schütz. Fr. Pat. 365,606, March 3, 1906.

See Eng. Pat. 25,867 of 1903; this J., 1905, 79.—E. S

Iodine; Process for the rapid extraction of —— from liquids containing iodine compounds. Soc. Franç. "La Norgine." First Addition, dated March 30, 1906, to Fr. Pat. 361,499, May 23, 1905. (See this J., 1906, 864.)

Vaseline oil, charged with iodine, is agitated with, for instance, a solution of sodium sulphite, until the colour is discharged. The de-iodised oil may then be separated, and more iodised oil added, and so on, until a concentrated solution is obtained. From the separated saline solution the iodine is set free and recovered by known means.—E. S.

Sulphur and cyanides from spent oxide, &c.; Process and apparatus for the extraction of ——. J. J. M. Bécigneul. Third Addition, dated April 7, 1906, to Fr. Pat. 345,071, July 23, 1904. (See this J., 1904, 1216; 1905, 1067; 1906, 583.)

To the hot toluene solution of the sulphur derived from the spent oxide, obtained as described in the main patent, cold water is admitted, as the solution descends through tubes into a separator having a funnel-shaped bottom. The sulphur is thus thrown down as a powder, and does not adhere to and clog the tubes through which it passes. In the receptacle, the toluene and water separate, the former rising, whilst the sulphur deposits at the bottom, and is withdrawn. Other alterations or additions relate to details of the apparatus.—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

English Patents.

Glass furnaces. H. G. Slingluff, Allegheny, Pa., U.S.A. Eng. Pat. 12,159, May 24, 1906. Under Int. Conv., June 29, 1905.

See U.S. Pat. 804,775 of 1905; this J., 1905, 1232.—T.F.B.

Muffle furnaces [for enamelling]. O. Forsbach, Cöln-Mülheim, Germany. Eng. Pat. 10,852, May 9, 1906.

See Fr. Pat. 366,021 of 1906; following these.—T. F. B.

French Patents.

Glass; Apparatus for the mechanical production of sheet ——. E. Fourcault. Fr. Pat. 366,383, May 18, 1906. Under Int. Conv., June 8, 1905.

In the apparatus described, the fined glass passes from the tank to a channel, surrounded with some heat-insulating material, such as sand, to prevent the glass from cooling. The channel is provided with a number of points of delivery for the glass, which is heated by burners opening into small chambers separating the drawing holes, and by other burners that can be used in the drawing holes themselves at the moment of starting. The drawing holes are heated by conduction through the walls of the small chambers, and by the direct action of the flame through adjustable openings. Above the drawing holes, drawing rolls are arranged, the diameter of which diminishes towards the ends, so that the rolls only act upon the edges of the sheets, and ensure the maximum pull with the minimum of pressure, the rolls only coming in contact with the sheet when the latter has already solidified. In each of the drawing holes is a special form of delivery, in the form of an inverted funnel, which allows the glass to be drawn from a depth, at which the consistency of the metal is better suited to drawing. The drawing slit of the delivery is constricted at the extremities in order to reduce the size of the swellings that form on the edges of the sheets.—W. C. H.

Muffle furnace [for enamelling]. O Forsbach. Fr. Pat. 366,021, May 9, 1906.

In the furnace described, the reheated air for combustion passes, prior to its mixture with the gases for heating, through channels arranged at the side of the flues which pass round or envelope the muffle, and is led from these channels into the furnace, by a channel arranged under the furnace, so that it enters this at a temperature about equal to that of the furnace. The details of the construction of a muffle furnace working on this principle are described.—W. C. H.

German Patent.

Iron; Process for enamelling ——. L. Hermsdorf and R. Wagner. Ger. Pat. 166,672, July 26, 1904.

In order to improve the fire-resisting qualities of the enamel, and to render it opalescent, two glazes are used, one containing phosphoric acid, and the other calcium compounds, whereby calcium phosphate is formed during the enamelling process. Suitable compositions for glazes are: (1) Potassium carbonate, 9·2; sodium carbonate, 12·2; alumina, 10·0; phosphoric acid, 14·0; boric acid, 13·8; silica, 40·4; and nickel oxide, 0·4 per cent. (2) Potassium carbonate, 5·3; sodium carbonate, 14·3; sodium fluoride, 5·2; aluminium fluoride, 3·5; alumina, 5·9; calcium fluoride, 16·9; boric acid, 14·9; silica, 33·6; and nickel oxide, 0·4 per cent. The glazes are mixed in the proportions of 100 parts of the first to 10—25 parts of the second. If a white glaze be desired, the nickel oxide is left out.—A. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 930.)

Concrete; "Flow" of —— under pressure. J. H. Woolson. Eng. News, New York, 1905, 459. Proc. Inst. Civil Eng., 1906, **164**, 86.

Steel tubes, 4 ins. in diameter, 12 ins. long, and from ⅛ in. to ¼ in. thick, were filled with a finely crushed stone concrete, which was allowed to set for 17 days. In the thicker tubes, the rods of concrete were able to bear a load of 150,000 lb. without injury, except a shortening of less than ¼ in. Two of the rods in the thinner tubes, however, began to show a marked deformation at about 120,000 lb., whilst at 150,000 lb. they were compressed 3¼ ins. and 3½ ins. respectively, and their diameters increased to about 5 ins. When the metal tubes were sawn apart, and removed, the concrete, though still quite solid, was found to have taken the exact shape of the distorted tube, thus indicating that under pressure it had behaved like a plastic material.—A. S.

Concrete; Effect of moisture on reinforced ——. Maynard. Rev. Techn., Paris, **26**, 453—457. Proc. Inst. Civil Eng., 1906, **164**, 87.

The author determined the variation in volume of a Portland cement mortar when placed in: (1), dry air; (2), damp air; (3), a limited quantity of fresh water; (4), fresh water frequently changed; (5), a limited quantity of sea-water; and (6), sea-water frequently changed. In the first case the volume gradually decreased with age; in the second, third, and fifth cases, it increased more or less rapidly; whilst in the fourth and sixth cases

an increase was at first apparent, but soon attained a maximum, after which a steady decrease took place, owing to the dissolving out of calcium hydroxide by the continually renewed water. In the case of structures in reinforced concrete, the variation in volume of the iron bars is dependent on stress and temperature alone, and is quite uninfluenced by the presence of moisture. Thus, as the climatic conditions vary, the stresses in the reinforced structure will also vary. If the thickness of the concrete envelope be considerable, the variation in stresses is great; whilst, if not, fissures are apt to form in the envelope, through which the moisture can gain access to the iron, which it rapidly corrodes. For instance, in a tank of reinforced concrete which had been exposed to the action of sea-water for 3½ years, many of the thin bars of iron were found to have been completely eaten away, a lustrous deposit of magnetic oxide of iron, Fe_3O_4, alone being left. It would seem that reinforced-concrete structures should be protected with some covering impervious to moisture wherever possible.—A. S.

Cement trade of Belgium. For. Off. Ann. Series, No. 3720. [T.R.]

THE prices for cement during the whole of 1905 remained very low, with a very small margin of profit. The Belgian cement industry has, for several years past, been unremunerative, and consequently cement has had to be sold at very low prices. This is due to: (1) overproduction; (2) the practical closure of the French market; (3) the establishment of numerous works in countries which previously imported large quantities from Europe. The cement trade at the present time (August, 1906) is decidedly active, and prices are becoming more and more steady. The export statistics of Belgian cement during the first six months of 1906 show a fair increase over those of the corresponding period of 1905. Down to June 30, 1906, the exports amounted to 380,355 tons, compared with 319,769 tons in the first six months of 1905. The augmentation is mainly due to large exports to Germany, which in the six months amounted to 66,325 tons; those of the first six months of 1905 being only 22,523 tons. The exports during the same period and the corresponding period of 1905 to the United States of America amounted respectively to 41,332 and 24,703 tons, the increase of 1906 being accounted for by the San Francisco earthquake, and the increasing use of cement-concrete. The exports to the United Kingdom fell off very considerably, declining from 113,067 tons in 1905 to 79,949 tons in 1906. The United Kingdom, however, still remains the principal market for Belgian cement, though not to such an overwhelming extent as heretofore. The Colonies also show a certain falling-off, though only of minor importance.

Principal exports of Belgian cement in 1905 compared with 1895.

1903	41,749,234	..	596,204
1904	39,085,471	..	548,497
1905	31,614,437	..	395,392

1 kin = 1·323 lb. 1 yen = florin.

Up to the end of May this year the value of cement exported had reached over 423,000 yen, whilst the figures for the corresponding period of the two preceding years were 198,000 yen and 217,000 yen respectively. That is to say, the quantity exported during the first five months of this year exceeded that for the whole of last year.

FRENCH PATENTS.

Bricks; Manufacture of light ——, *composed of clay or marl and vegetable materials.* B. Giscard. Fr. Pat. 366,291, Feb. 17, 1906.

ACCORDING to the process described, bricks and similar bodies can be produced, of relatively light weight, by combining with clay or marl such substances as sawdust, bran, various straws, maize heads, oat or wheat husks, various kinds of fodder, foliage, shavings and wood charcoal, oakum, cork, &c., all ground very fine.—W. C. H.

Stone and marble; Manufacture of artificial ——. T. M. Thom. Fr. Pat. 365,652, April 20, 1906. Under Int. Conv., April 20, 1905.

SEE Eng. Pat. 8804 of 1905; this J., 1906, 537.—T. F. B.

Building materials. W. Spittler. Fr. Pat. 366,095, May 11, 1906.

THE building materials described are made of coarse particles of wood (shavings, fibres, bark, &c.) stuck together so as to form a thoroughly solid body, which is refractory and impermeable to sound, by means of some known agglutinant used in the manufacture of artificial stone and wood, such as magnesium chloride, burnt magnesia, &c.—W. C. H.

Cement to resist sea-water; Process for the manufacture of a ——. E. Bougleux. Fr. Pat. 365,869, March 12, 1906. Under Int. Conv., March 12, 1905.

THIS cement is made by adding "hydraulites," such as

puzzuolana, trass, &c., to the cement materials. The addition may be made: (1) To the raw cement materials before they are introduced into the kiln; (2) as a very fine powder introduced into rotary kilns, before, during, or after the formation of the clinker, or in the case of ordinary cement kilns, during the burning whilst the material is still red; (3) and also with or without the preceding additions, during the grinding of the clinker, either hot or cold.—W. C. H.

Cement; Process and apparatus for burning —— in rotary tubular furnaces. T. M. Morgan. Fr. Pat. 365,523, April 24, 1906.

SEE Eng. Pat. 6046 of 1906; this J., 1906, 848.—T. F. B.

Cement; Process and apparatus for the manufacture of ——. B. E. Eldred. Fr. Pat. 365,579, April 25, 1906.

BY this process, the two operations of calcining and of fritting the raw materials for the production of Portland and other cements, are carried out as two distinct phases of the manufacture, and in separate furnaces, since a relatively low temperature is sufficient for the calcining process, and a high temperature is necessary for the fritting process. By means of a regenerative system the heat of the gases escaping from the fritting furnace is used to heat the gas and air employed in heating that furnace, and similarly the heat of the gases escaping from the calcining furnace is used to heat the gas and air supplied to it. The apparatus for manufacturing cement according to this process consists of two furnaces heated by producer gas, in each of which the temperature, condition of the fire, and the rate of supply of material, can be regulated independently and without alteration of the corresponding conditions existing in the other furnace. The two furnaces may be entirely separate, or they may be combined into a single structure, in which case their adjacent ends are fitted into a common hood or box.
—W. C. H.

Cement for coatings, pavements, and mosaics, especially applicable for binding together mother-of-pearl. H. Gombaud. Fr. Pat. 366,122, May 12, 1906.

A CEMENT for coatings, pavements, and mosaics, and specially applicable for binding together mother-of-pearl, is composed of commercial magnesia, powdered marble, or "other silicious product," and of mother-of-pearl flakes, bound together with a solution of magnesium chloride, to which is added 10 per cent. of zinc sulphate, and 10 per cent. of potassium silicate, with or without the addition of colouring material and wood sawdust.—W. C. H.

Cement; Manufacture of Portland ——. H. Peters. Fr. Pat. 366,600, May 26, 1906. Under Int. Conv., Sept. 22, 1905.

SEE Eng. Pat. 19,180 of 1905; this J., 1906, 885.—T. F. B.

GERMAN PATENT.

Cork substitute; Process for the manufacture of a ——. J. Fuchs. Ger. Pat. 167,780, Jan. 25, 1905.

THE process claimed consists in acting upon copper or nickel, or oxides of these metals, with acetylene under the influence of pressure and heat. Copper or nickel, or an oxide of one of these metals, is placed in a rotating drum of aluminium, and heated to 230° C. Acetylene under a pressure of 15 cm. of mercury is then introduced, and a similar pressure is exerted on the drum. The contents of the drum are stated to be converted into a compact, light brown mass ("cuprene"), which can be cut or moulded into any desired form. It has a specific gravity half as high as that of cork, and an elasticity equal to that of the latter. It is stated to be suitable for use as a filling for walls and floors, being a non-conductor of heat and serving to deaden sounds, and also for filling the tyres of bicycles and automobiles.—A. S.

X.—METALLURGY.

(*Continued from page* 935.)

Steel; Structure of hardened and tempered ——. E. Heyn and O. Bauer. Mitth. königl Materialprüfungsamt zu Gross-Lichterfelde West, 1906, **24**, 29—59.

THE authors' investigations were made with a tool-steel of eutectoid composition (0·95 per cent. of carbon). In the first series of experiments, test-pieces of the steel were hardened by quenching in cold water from a temperature of 900° C., and were then tempered by reheating for varying periods of time at temperatures ranging from 100° to 640° C. In the second series of experiments the test-pieces were quenched in different liquids from a temperature of 900° C. The test-pieces after treatment were examined with respect to hardness, solubility in dilute sulphuric acid, and behaviour on etching with alcoholic hydrochloric acid (1 c.c. of acid in 100 c.c. of absolute alcohol). Microphotographs are appended to the paper. The results obtained showed that in the transition from martensite to perlite on tempering at successively higher temperatures, there is a well-defined intermediate stage (corresponding to a tempering temperature of 400° C), for which the authors propose the name *osmondite*. Troostite is retained as the generic name for the stages between martensite and osmondite, and sorbite for those between osmondite and perlite. Osmondite is more soluble in 1 per cent. sulphuric acid than troostite or sorbite. When troostite or osmondite is dissolved in 10 per cent. sulphuric acid, the residue contains no iron carbide, but some "free carbon," the greatest quantity being obtained with osmondite. A special name is needed for this form of carbon; it is not present in the steel, but is produced on dissolving the metal in dilute acid. Iron carbide is found in the insoluble residue only in the case of sorbite. The coloration of tempered steels on etching with alcoholic hydrochloric acid, as also the coloration of troostite and osmondite in hardened steel, is due to a film of "free carbon" which is deposited on the surface; the coloration is accordingly deepest with osmondite. The results of the second series of experiments indicate that all forms of quenching of the steel under examination are equivalent to an ideal undercooling, with consequent complete conversion of the perlite into martensite, followed by a more or less marked tempering effect, with formation of troostite or of troostite and osmondite, the intensity of this tempering being dependent upon the rate of cooling.—A. S.

Steels containing 0·5 and 0·8 per cent. of carbon; Heat treatment of ——. C. E. Corson. Bull. Amer. Inst. Min. Eng., 1906, 725—742.

THE experiments were made with acid open-hearth steels containing 0·50 and 0·75 per cent. respectively of carbon. The test-pieces were heated to temperatures up to 900° C., and then cooled in the air, and also immersed in ashes and in lime. In general the results obtained were analogous to those obtained with other grades of steel examined by different investigators. As the time occupied in cooling increased, the tensile strength and contraction decreased, whilst the elongation showed a slight increase. Micrographs illustrating the structure of the test-pieces are given in the paper. Sauveur (Metallographist, 2, 267) has stated that "hot work, as such, has no influence upon the structure of the metal. Indirectly, however, by retarding crystallisation until a lower temperature is reached, it may have considerable effect on the structure, but the same results could be attained by heat treatment alone, *i.e.*, by reheating the unworked metal to the temperature from which the worked piece was allowed to cool undisturbedly. In order to test this statement, two test-bars were prepared from one and the same ingot. One, after being cooled, was reheated in a coke furnace to cherry-redness; and the other was hammered until it had cooled to cherry-redness (about 1250° F.). The two bars were then cooled side by side in the air. The results were as follows:

Treatment.	Tensile strength.	Elongation on 4 in.	Reduction of area.
	lb. per sq. in.	per cent.	per cent.
(1) Hammered for about 2 mins. to cherry-redness (2) Cooled, and then re-heated to match No. 1 as it left the hammer ...	109,271	15	26

Steel ingots; Segregation in ——, and its effects on the mechanical properties of steel. J. E. Stead. Brit. Assoc., Section G, York, 1906. Engineering, 1906, **82**, 405.

THE author gives a general summary of the present position of our knowledge on segregation in steel, and its effects on the mechanical properties of the metal. He states in conclusion that although segregation should be avoided, it is not so great an evil as is frequently asserted, unless accompanied by unsoundness. Unsoundness without segregation will equally lead to premature failure. In the author's experience of the steel rails which break when in use on English railways, not more than one-sixth are axially segregated, and even in these it is doubtful whether the rails were not initially unsound. The cause mainly responsible for failure is unsoundness, either internally or externally. The author's opinion is that the only reliable method of producing perfectly sound steel is by compression of the molten metal in the mould, but fairly good results can also be obtained by the addition of aluminium or silicon.—A. S.

Iron and steel structures; Protecting —— with paper. L. H. Barker. Paper read before the Amer. Soc. for Testing Materials, June 30, 1905. Proc. Inst. Civil Eng., 1906, **164**, 41—42.

NUMEROUS experiments with different kinds of paints did not give satisfactory results. Good results were obtained, however, by the use of "paraffin paper." The iron is carefully cleaned from rust by means of stiff wire brushes, then a kind of "tacky" paint is applied, and the paper is pressed tightly on the painted surface, the joints of the paper being made to slightly overlap. The paper, as soon as it is in place, is ready for the first coat of paint. After exposure to smoke for two years and three months, it was found that the paper and the first or adhesive coat of paint were quite intact, and in many places the paint was still not dry; the surface of the steel was just as when painted. Steel protected in this way was also not affected by exposure to dampness and sewer gases.—A.S.

Platinum-silver alloys. [*Separation of platinum from gold, iridium*, &c.] J. F. Thompson and E. H. Miller. J. Amer. Chem. Soc., 1906, **28** [9], 1115—1132.

IT has long been known that platinum, alloyed with silver, will dissolve to some extent in nitric acid, but conflicting results have been obtained by different workers. Thus Winkler (Z. anal. Chem., 1874, 368) regards the strength of acid as of small importance, whilst J. Spiller (this J., 1897, 539), recommends acid of sp. gr. 1·42. Both find that a residue is left, whereas N. W. Perry (Eng. and Min. J., Jan., 1879) states that the whole dissolves. To account for these and other results the authors have made a study of the melting points and cooling curves, microstructure, specific gravities, and electrical conductivities of a series of alloys, the platinum contents of which ranged from 0·5 to 57 per cent. Great care was taken to free the platinum used from iridium, and to render the alloys quite homogeneous. For their analysis the parting method, with sulphuric acid, was employed, but it was found necessary, where the platinum amounted to 20 per cent. or more, to dissolve the residue, after weighing, in *aqua regia*, and precipitate the silver retained, which amounted in one case to 2·7 per cent. No appreciable amount of platinum is dissolved by the acid during the time of heating. (Compare Delépine, this J., 1906, 304.) It was found that in no case would the alloy dissolve completely in nitric acid (sp. gr. 1·1 and 1·4); some platinum was always dissolved with the silver, and some silver always remained with the residues. The separation of platinum from gold, iridium, &c., in one operation, by alloying with silver and parting with nitric acid, is therefore impossible. From a study of the cooling curves and microstructure, the authors conclude that the alloys consist of a number of platinum-silver compounds of different solubilities, the relative proportions of which depend on the rate of cooling. Hence the irregular results obtained in parting with nitric acid.—F. SODN.

Carbon in steel; New colorimeter for the determination of ——. C. H. White. XXIII., page 1007.

ENGLISH PATENTS.

Tin; Process for extracting —— from ore. R. W. E. MacIvor and M. Fradd, London. Eng. Pat. 10,943, May 25, 1905.

TIN ore or oxide is exposed to the action of producer- or water-gas whilst being heated and agitated, preferably in a closed horizontal vessel to which a slow, rotatory movement is communicated.—E. S.

Pyritic ores containing gold, silver, or other valuable metals; Treatment of ——. W. Blackmore and A. Howard, London. Eng. Pat. 17,839, Sept. 4, 1905.

THE pyritic ores are roasted at about 800° F. in the presence of air and steam admitted in such proportions as to oxidise the sulphides, as far as possible, into sulphates. The sulphurous gases emitted in the process are absorbed by water, and the solution is used in lixiviating the roasted ore. Or, the roasted ore may be washed with water containing about 5 per cent. of sulphuric acid, the object being to remove sulphates of iron, copper, cobalt, and nickel, the latter metals being recovered by usual means. The residual ore is then treated to obtain the precious metals by the cyanide or chlorination methods. If the ores contain lead or zinc, the residues are further treated by smelting processes to recover them. Reference is made to Eng. Pat. 28,992 of 1904 (this J., 1906, 481).

—E. S.

Lead and silver; Process for obtaining —— from their ores. J. Asbeck, Westerwald, Germany. Eng. Pat. 23,408, Nov. 14, 1905.

SULPHIDE ores of lead and silver, containing, in addition, sulphides of copper and iron, are decomposed by treatment with a fused halogen salt, *e.g.*, sodium chloride or zinc chloride, to which oxide of lead or of zinc is added, in quantity at least equivalent to the amount of copper or iron in the ore. The lead and silver are afterwards separated in the metallic state by means of the electric current or by the addition of an electro-positive metal, *e.g.*, zinc. The function of the added zinc oxide or lead oxide is to convert the copper and iron compounds into oxides, and to prevent the formation of chlorides of these metals, which, if formed, would afterwards be partly reduced, thus contaminating the silver and lead obtained, and would also, as far as they remained unreduced, spoil the bath for another treatment of a fresh quantity of ore.

—A. G. L.

Metalliferous ores or compounds; Treatment of —— preparatory to smelting the same. F. Heberlein, London. Eng. Pat. 26,277, Dec. 16, 1905.

METALLIFEROUS (iron or manganese) ores or compounds, in a fine state of division, are mixed with coal or other fuel, moistened with water if necessary, and then burnt, preferably in a tip-apparatus, of conical or spherical form, using an air-blast of gradually increasing force. The sintered mass obtained is treated as usual in a blast-furnace.—A. G. L.

Ores; Process and apparatus for smelting ——, and converting mattes. A. M. Day, Salt Lake City, U.S.A. Eng. Pat. 3528, Feb. 13, 1906.

SEE U.S. Pats. 812,186 and 812,765 of 1906; this J., 1906, 269.—T. F. B.

Iron compounds; Method of desulphurising and nodulising substances containing ——. T. C. King, New York. Eng. Pat. 60, Jan. 1, 1906.

Iron ores; Treatment of small mine or waste products of calcined —— *for the more complete extraction of iron therefrom.* A. Hodgkinson, Stoke-on-Trent. Eng. Pat. 4999, March 1, 1906.

IT has been found that the calcined waste products of ironstone seams known as "small mine," and the calcined pieces of stone or rock containing iron, left on the mine hearths after the puddle or furnace mine has been removed, cannot be worked up except when the proportion of moisture present is not less than 3 nor more than 35 per cent. According to the present patent, the waste is either heated or moistened until the proportion of water is within the limits mentioned; it is then moulded into blocks, and pressed, whereby lumps are produced which, after being annealed, can be utilised in puddling or other furnaces. Reference is directed to Eng. Pat. 4537 of 1889 (this J., 1890, 519).—A. S.

Iron; Processes for converting cast —— *into steel or malleable iron.* M. A. Hunter, Philadelphia, U.S.A. Eng. Pat. 8507, April 9, 1906.

SEE Fr. Pat. 365,159 of 1906; following these.—T. F. B.

Filters for separating water or solution from solids, such as slimy ores, pulp, and the like. G. Ridgway, Kalgoorlie, W. Australia. Eng. Pat. 11,623, May 18, 1906.

A NUMBER of flat, hollow filter-frames are attached by radiating arms to a central rotating spindle, and are rotated above an annular trough. The spindle is hollow, and is divided into three separate compartments, each of which has a separate outlet, and is also connected to each of the filter-frames by a separate valved pipe. In two of these compartments a vacuum is maintained, and in the third a pulsating movement is set up by a plunger which produces a vacuum and a pressure alternately. The annular trough is divided by partitions into three or more compartments: the first contains the "pulp," the second the wash water, and the last serves to receive the exhausted material, which falls through the open bottom into trucks placed underneath. At the outer side of each filter-frame is a roller, which runs on an undulating track forming the outer edge of the annular trough. Three corresponding concentric, undulating tracks are placed round the spindle between it and the inner side of the annular trough; each of these tracks guides and operates a roller or lever which opens or closes a valve on one of the pipes leading from the filter-frame to one of the chambers in the hollow spindle. The apparatus works as follows, the cycle of operations of only one filter-frame being described for the sake of simplicity, and starting with the filter-frame, which has a permeable lower face, in the position which it occupies just before entering the pulp compartment of the trough. As the frame moves round and approaches the division, the roller is raised by the elevation of the undulating outer track, and the frame is lifted over the division wall, and lowered into contact with the pulp in the following compartment of the trough, at the same time the valve on the pipe which communicates with the first vacuum chamber is opened by its roller passing over an elevation on its own undulating track, and some of the pulp is sucked on to the lower surface of the frame. It is held there by the suction, and the strong liquor passes through into the first vacuum chamber. As the frame approaches the next division, it is lifted over as before, and lowered into the washing liquid in the next compartment. At the same time the connection to the first vacuum-chamber is closed and that to the second is opened, so that the washing liquid is drawn through the adhering cake of material into a separate chamber. Finally, the frame is again lifted over the next division, and passes over the discharge compartment. The connection to the pulsating chamber is now opened by the roller, as in the other cases, and that to the second vacuum chamber closed, and the alternate pressure and vacuum applied to the filter-frame loosens the cake, which falls into the truck placed below. The contents of the pulp and wash-water compartments may be kept in motion by suitable agitators, and the levels kept constant by float chambers. The pulp-, washing-, and discharge-chambers may also be arranged in a line instead of in a circle.—W. H. C.

Aluminium and its alloys; Soldering of ——, *and a solder therefor.* M. Gruber, Berlin. Eng. Pat. 12,599, May 30, 1906.

THE solder contains 10 parts of copper, 2 of aluminium, 25 of zinc, 60 of tin, and 3 of cadmium. It is stated to have a low melting point, and is applied, with the aid of paraffin as a flux, by means of a soldering bit.—E. S.

UNITED STATES PATENTS.

Cast-iron articles; Method of making ——. A. W. Slocum, Assignor to C. V. Slocum, Pittsburg, Pa. U.S. Pat. 830,536, Sept. 11, 1906.

MOLTEN cast iron from a melting furnace is mixed with 1 per cent. or less of titanium oxide, and then cast. The titanium oxide is reduced by the carbon of the cast iron. —A. S.

Scrap-brass; Process of treating ——. H. J. Krebs, Wilmington, Del. U.S. Pat. 830,601, Sept. 11, 1906.

THE brass is melted in a cupola furnace, the zinc being oxidised and volatilised, and the purified copper subsequently discharged. From the oxidation products, the coarser particles are first removed by settling; then, after cooling, the zinc oxide is collected in bags or the like, and the residual fume is treated with an acid solution for the production of a zinc salt.—A. S.

Scrap-brass; Process of treating ——. H. J. Krebs, Wilmington, Del. U.S. Pat. 831,010. Sept. 11, 1906.

THE process is essentially the same as that described in U.S. Pat. 830,601 (see preceding abstract), except that no provision is made for collecting zinc oxide from the cooled fume, the latter being treated directly for the production of a zinc salt.—A. S.

Ores; Apparatus for cyaniding ——. T. L. Rankin, Sackett Harbor, N.Y. U.S. Pat. 830,615, Sept. 11, 1906.

THE ore is treated with cyanide solution in two rotary leaching cylinders with a valved connecting pipe. The cylinders are lined with wood, and have spiral wooden ribs starting at each end and ending near the middle. Compressed air is admitted to the first cylinder, and when the leaching operation in this is finished, the valve in the connecting pipe is opened, and the excess of compressed air allowed to pass into the second cylinder, to assist the leaching process therein. The foul air and "gases" from the leaching cylinders are led into the bottom of a receptacle containing a liquid capable of absorbing the "gases," the air being subsequently allowed to escape. This receptacle has a perforated partition above the inlet for the air and "gases," and is packed with "obstructing substances" above the partition.—A. S.

FRENCH PATENTS.

Copper; Process of extracting —— *from minerals.* G. R. M. Sweeting. First Addition, dated June 6, 1905, to Fr. Pat. 360,071, Feb. 11, 1905 (this J., 1906, 485).

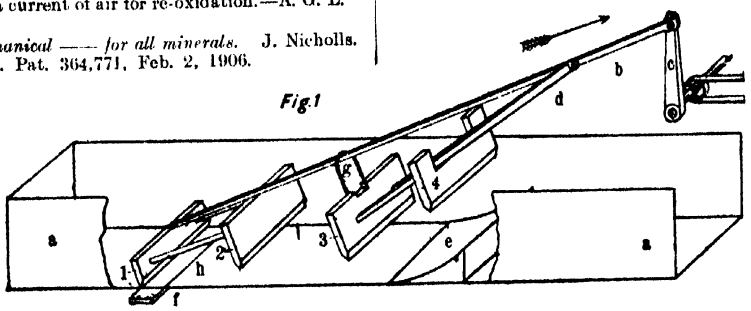
THE liquid left in the anode compartment at the end of the electrolysis, by which the copper is deposited, is evaporated by hot waste gases passing through a flue above the tank. On allowing the liquid to cool, ferric sulphate crystallises out, and sulphuric acid, of a strength up to 66° B., is left in the mother liquor. The ferric sulphate obtained is then distilled in retorts heated to a white heat for the production of colcothar and fuming sulphuric acid as usual.—A. G. L.

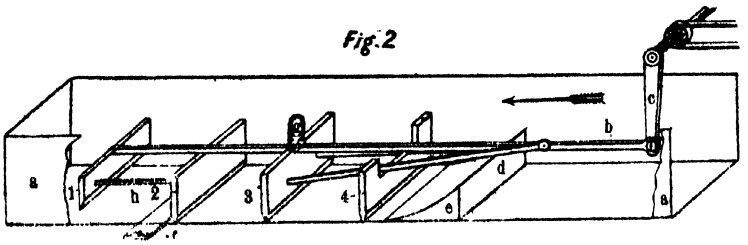
Castings of copper and copper alloys; Process for the production of dense and homogeneous ——, *by means of the addition of an alkali carbonate.* Laboratorium für Chem. Feuerschutz- und Löschmittel Conrad Gautsch G.m.b.H. Fr. Pat. 365,733, April 28, 1906.

In order to produce sound castings of copper, bronze, &c., and to readily introduce iron or steel into such alloys, a small quantity (0·2 to 0·4 per cent.) of sodium bicarbonate is added to the metal, preferably partly before and partly after the fusion. The salt is added in addition to the phosphorus used for deoxidation, but without the subsequent use of a current of air for re-oxidation.—A. G. L.

Washer; Mechanical —— *for all minerals.* J. Nicholls. Fr. Pat. 364,771, Feb. 2, 1906.

Fig. 1





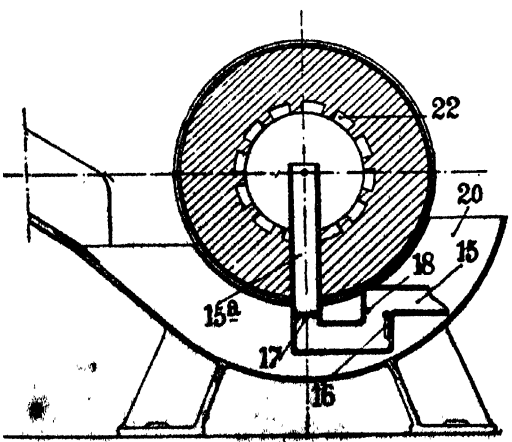


Fig. 2

The washer consists of a tank, *a*, in which the mineral to be treated is stirred up with water by means of a shaft capable of a reciprocating motion. Directly attached to this shaft are two rabbles, 1 and 2, whilst a number of others, 3 and 4, are attached to two arms, *d*, pivoted on the shaft, the end rabble, 3, being also guided by the staple, *g*, which slides along the shaft. The rabble, 1, is not quite as wide as the others, and hence does not come into play until the shaft has been raised to some extent.—A. G. L.

Rotary furnace for treating minerals and all combustible bodies. A. Ducco. First Addition, dated March 10, 1906, to Fr Pat. 364,366, March 10, 1906.

The addition consists in arranging the interior channels or flutings, 22, so that they form only a slight angle with the axis of the rotary cylinder, and in providing a cylindrical extension at the discharge end furnished with an interior helical blade which delivers the treated material into a closed chamber provided with a discharge hopper. The charging device is shown in the figure, and consists of a tube, 15, 15A, bent as shown, and provided with self-closing and opening flap-valves, 16 and 17, one of which always remains closed and shuts off communication with the external air. As the cylinder rotates, the pipe, 15, scoops up some of the material from the trough, 20, which material falls into the bend. As the cylinder continues to rotate, and the pipe, 15A, comes into its highest position, the flap, 16, falls on to its support, 18, and closes the open end to the air. At the same time the flap, 17, opens, and the material in the bend drops down the pipe, 15A, into the cylinder.—W. H. C.

Furnaces; Metallurgical ——. A. Farkas and J. de Moya. Fr. Pat. 365,940, May 5, 1906.

Rapid heating or fusion of minerals or metals is effected by introducing into a closed furnace, gas from one or more independent producers, and at the same time blowing in air from one or more tuyères. By varying the proportions of air and gas, any desired degree of oxidation or reduction may be obtained. No chimney is necessary. —A. G. L.

Cast iron or cast steel; Process of producing —— *by means of the basic converter.* Soc. Anon. des Mines du Luxembourg et des Forges de Sarrebruck. Fr. Pat. 364,785, March 31, 1906.

A basic mineral capable of evolving a large quantity of gas when heated, preferably limestone, is added to the charge in the converter before or during the blow; the temperature is then raised so as to evolve the gas, and to cause the lime to combine with the phosphoric acid produced, after which the temperature is allowed to fall to a point convenient for casting.—A. G. L.

Steel; Manufacture of —— *in the Bessemer converter or Talbot furnace, with basic or neutral linings.* H. J. B. Picaud. Fr. Pat. 364,837, April 2, 1906. Under Int. Conv., April 3, 1905.

To the mass in the converter or furnace a flux, such as fluorspar, is added. This addition increases the rapidity with which the lime takes up the phosphoric anhydride formed during the blow to such an extent that the metal

is free from phosphorus before it has become completely decarburised. The resulting slag can be used as a fertiliser in the same way as ordinary Thomas slag.—A. G. L.

Iron; New method for the production of reduced —— in the spongy state. F. C. W. Timm. Fr Pat. 365,878, April 7, 1906. Under Int. Conv., April 10, 1905.

Carbon dioxide is passed through a producer containing an incandescent mass of coke, which reduces it to carbon monoxide. This is then passed whilst hot through the iron-bearing mineral to be reduced, and in reducing this becomes converted into twice the initial quantity of carbon dioxide. Half of the gas having been removed through suitable flues, the remainder goes through the same cycle again, until, after about 10 minutes, the producer has become too cold to work. The process is then interrupted, and another producer interpolated in place of the first, which is in the meanwhile revivified by blowing air through it at such a rate as to produce mainly carbon dioxide. The products of combustion produced in this way are made to heat the carbon monoxide on its way to the mineral-containing chamber, by means of a Cowper stove; or else they serve to heat the chamber itself.—A. G. L.

Cast-iron; Process for converting —— into steel or wrought iron. M. A. Hunter (*née* Webb). Fr. Pat. 365,159, April 10, 1906.

The process consists in heating the cast iron, in bars or pigs, to a temperature approaching but below its melting-point (about 925° to 980° C.), and then treating it with liquid, vaporised, or atomised sulphuric acid. This treatment eliminates most of the carbon, and changes the physical characteristics of the metal so that it can be forged.—A. G. L.

Iron; Process of casting ingots of —— without the addition of appreciable quantities of aluminium or silicon, and without air-holes at the surfaces. Rheinische Metallwaaren- u. Maschinenfabrik. Fr. Pat. 365,345, April 17, 1906. Under Int. Conv., May 17, 1905.

Sound ingots of iron and mild steel are obtained without the use of appreciable quantities of aluminium or silicon, by casting in moulds which widen considerably towards the top, so as to allow of the ready escape of the air-bubbles liberated during the cooling at the sides of the moulds.—A. G. L.

Steel; Process for the manufacture of ——. V. Defays. Fr. Pat. 365,671, April 26, 1906. Under Int. Conv., April 29, 1905.

One or more Siemens-Martin furnaces are arranged close to one or more gas producers in order to be able to utilise the sensible heat of the producer for the conversion of the iron into steel. This is done by charging the producer not only with the usual combustibles (coke, &c.), but also with the cast iron and materials, such as ferric oxide, lime, &c., designed to assist in the process. On blowing air through the producer, the iron melts and runs into a holder at the bottom of the producer, from which it flows into the Siemens-Martin furnace.—A. G. L.

Metalliferous substances; Nodulising and treating ——. T. C. King. Fr. Pat. 365,432, April 20, 1906. Under Int. Conv., May 4, 1905.

The object of the invention is to form the metalliferous substances into nodules, containing the metals in the form of oxides, without using any binding agent which shall either leave objectionable impurities in the nodules or sensibly diminish their content in metal. To this end, the finely-divided materials are either mixed with water only, or else with a binding agent, *e.g.*, tar, hydrocarbons, or carbohydrates, which is volatile at a moderate temperature. The mixture is then heated at about 650° C., and agitated so as to form itself into nodules of the required size. This treatment also removes any sulphur, arsenic, &c., present in the materials, and the resulting nodules are very porous. (*Cf.* U.S. Pat. 794,673, this J., 1905, 894; and Fr. Pat. 366,413, this J., 1905, 1311.)—A. G. L.

Minerals; Process for the treatment of ——. J. Savelsberg. First Addition, dated April 21, 1906, to Fr. Pat. 351,535, Feb. 15, 1905 (this J., 1905, 894).

The invention claimed in the principal patent is now applied to minerals containing sufficient sulphur without further admixture, and to minerals whose treatment does not require the addition of sulphur, *e.g.*, iron ores. Such minerals are simply mixed with carbon, and treated with the air-blast in a converter until they have become sintered together, and can be treated as usual in a blast furnace. The invention is, of course, especially applicable to such minerals as occur in a finely-divided condition.—A. G. L.

Magnetic material and process of making same. R. A. Hadfield. Fr. Pat. 365,615, May 4, 1906. Under Int. Conv., June 8, 1905.

See Eng. Pat. 22,130 of 1905; this J., 1906, 592.—T. F. B.

Alloy for bearings; Metallic ——. Siemens und Halske A.-G. Fr. Pat. 366,060, May 10, 1906. Under Int. Conv., May 22, 1905.

See Eng. Pat. 10,513 of 1906; this J., 1906, 816.—T. F. B.

German Patents.

Zinciferous ores and metallurgical products; Process for the treatment of ——. Zinkgewinnungs-Ges. m. b. H. Ger. Pat. 165,455, March 24, 1905.

The zinciferous material, after being roasted if necessary, is treated with sulphuric acid, and from the solution the zinc is precipitated as hydroxide by means of sodium hydroxide. The residual solution is causticised with lime for the regeneration of sodium hydroxide. If the original material contains a sufficient quantity of lime, it is used in place of fresh lime for causticising the residual solution. In the case of ores containing dolomite, the solution obtained by treatment with sulphuric acid is divided into two portions in such a manner that the quantity of magnesium contained in one part is equivalent to the amount of zinc contained in the other. The first portion is treated with sodium hydroxide, and the precipitate of zinc and magnesium hydroxides is used to precipitate the zinc from the second portion.—A. S.

Zinciferous ores and metallurgical products; Process for the treatment of ——. Zinkgewinnungs-Ges. m. b. H. Ger. Pat. 169,138, May 24, 1905. Addition to Ger. Pat. 165,455, March 24, 1905 (see preceding abstract).

The solution of zinc and magnesium sulphates obtained by treating the material with sulphuric acid is divided into two portions. From the first portion, zinc and magnesium hydroxides are precipitated by quicklime, and the zinc is dissolved out of the precipitate by treatment with a solution of sodium hydroxide and sodium sulphate. The solution is used for leaching a fresh quantity of ore with sulphuric acid diluted with sodium sulphate solution, whereby the sodium zincate is converted into sodium sulphate, and the whole of the zinc and the magnesium are precipitated as hydroxides. The precipitate is used for treating the second portion of the solution first obtained, the magnesium hydroxide precipitating the zinc as hydroxide.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 937.)

(*A.*)—ELECTRO-CHEMISTRY.

Ferromanganese anodes in solutions of caustic potash. G. R. White. J. of Physical Chem., 1906, 10, 502—513. Chem. Centr., 1906, 2, 999.

In the anodic electrolysis of ferromanganese in alkaline solutions, there is formed sometimes permanganate and sometimes manganate. It has been found that the

formation of manganate is due to the presence of reducing impurities. If these latter be absent, permanganate only is formed both in 2 per cent. and 10 per cent. caustic potash solutions; reduction to manganate then takes place only on increasing the temperature to 95° C. The reduction is effected by the action of hydrogen liberated at the cathode; a spontaneous evolution of oxygen was never observed. On electrolysing at 95° C. alkali ferrate is produced as well as manganate, and iron is deposited at the cathode. Anodes of metallic manganese are readily oxidised to permanganate. Manganous hydroxide, $Mn(OH)_2$, formed by the action of caustic potash on manganese, can be oxidised electrolytically to manganese dioxide, but not to permanganate. The anodic formation of permanganate must therefore proceed directly, without the intermediate production of compounds of a lower degree of oxidation. A. S.

Copper; Electrolytic determination of ——. F. Foerster. XXIII., page 1007.

Lead; Electrolytic separation of — — from acetic acid solutions. R. C. Snowden. XXIII., page 1007.

English Patents.

Accumulators; Electric ——. H. N. Warren, G. Busschots, and J. M. Wood, Liverpool. Eng. Pat. 17,674, Sept. 1, 1905.

This invention relates to an improvement in the manufacture of accumulators, which consists in incorporating in the mixture used for covering the plates, or in the electrolyte, one or more compounds of selenium, such as the selenates or selenites of ammonium, potassium, or sodium, or selenious acid, for the purpose of preventing the "sulphating" of the plates or elements.—B. N.

Active material; Use of a special —— for manufacturing accumulators. C. Jeantaud, Paris. Eng. Pat. 52, Jan. 1, 1906. Under Int. Conv., Jan. 5, 1905.

This invention relates to the use of a novel form of lead, its oxides, or salts, unalloyed or mixed with ordinary lead or its compounds, in the manufacture of electric accumulators. The lead is obtained by the electrolysis of a mixture of a solution of an alkali plumbate with an alkali plumbite, the density of the solution being 15° B. With a current density of not less than 2 ampères per sq. dm. of cathode surface, the novel form of lead is deposited on the cathode as dullish-grey crystals, having a smaller electro-chemical equivalent than that of other substances now used. This form of lead is said to give an E.M.F. about 5 per cent. higher than ordinary lead, and to have nearly double the capacity of the ordinary metal.—B. N.

Insulating material; Manufacture of [electrical] ——, and the coating of metal and other surfaces therewith. J. Connolly, Manchester. Eng. Pat. 3345, Feb. 10, 1906.

Soft stearine pitch is applied in a melted or dissolved condition to the surface to be coated, and is then heated to a temperature exceeding 200° C., but not above 300° C. An arrangement is described for passing wires or the like through the stearine pitch, the coated material being then passed upwards between heated surfaces, which converge above towards the wire. The covered material is thus gradually raised in temperature, and the pitch assumes lacquer-like properties, becoming tough and incapable of being melted or dissolved.—B. N.

Furnaces; Electrical ——. B. Platschiek, Paris. Eng. Pat. 23,526, Nov. 15, 1905.

See U.S. Pat. 826,962 of 1906; this J., 1906, 936.—T. F. B.

Persulphates; Process for electrolytically producing ——. E. Teichner and P. Askenasy, Nuremberg, Bavaria. Eng. Pat. 2823, Feb. 5, 1906.

See Fr. Pat. 351,613 of 1905; this J., 1905, 896.—T. F. B.

Ozone; [Electrical] Production of ——. E. Applegarth and J. R. Quain, London. Eng. Pat. 3905, Feb. 16, 1906.

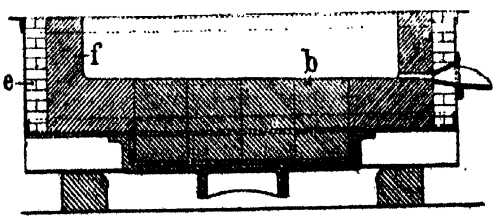
The ozoniser comprises an inner glass tube containing an electrode in a vacuum; surrounding this is a double outer glass tube, the ends of the two outer tubes being sealed together so as to form an annular space between them, which is made vacuous, and in which the second electrode is placed. The gas to be ozonised is circulated, by means of a fan, between the outer surface of the inner tube and the inner surface of the double tube. The electrodes are suitably connected to a transformer and generator, the latter also driving the fan.—B. N.

Electrolytic apparatus. F. McDonald, Johnsonburg, Pa., U.S.A. Eng. Pat. 4716, Feb. 26, 1906.

See U.S. Pat. 814,864 of 1906; this J., 1906, 380.—T.F.B.

French Patents.

Filaments for incandescence lamps. A. Just and F. Hanaman. Third and Fourth Additions, dated Feb. 14 and 19, 1906, to Fr. Pat. 347,661, Nov. 4, 1904. II., page 976.



Electrolysis without porous diaphragm; Process and apparatus for ——. G. Rambaldini. Fr. Pat. 364,826, April 2, 1906. Under Int. Conv., April 3, 1905.

In order to maintain a uniform *régime* in the electrolysis, without diaphragms, of a solution giving one soluble product and one product which is gaseous or solid, it is necessary to adopt special measures for the regeneration of the electrolyte. The present invention consists in adding, in the form of a solution, only a portion of fresh electrolyte, equivalent to that decomposed in contact with the electrode at which a soluble product results; the other portion of the fresh electrolyte, equivalent to that decomposed at the electrode at which the insoluble or gaseous product is formed, being added as anhydrous salt. The regeneration of the electrolyte can be carried out in an auxiliary vessel or vessels through which the electrolyte or its two fractions are caused to circulate. In the apparatus which is employed for carrying out the process, the electrodes are disposed horizontally in superposed layers of the electrolyte, which are separated solely by their difference in density. The removal of one or both fractions of the electrolyte is carried out by causing a circulation of the two superposed layers. Any gaseous products formed at the electrodes are withdrawn by covering the electrodes with bells, or by using a closed cell.—R. S. H.

Electrolysis of liquids; Apparatus for ——. L. Londei. Fr. Pat. 364,978, April 6, 1906. Under Int. Conv., Sept. 29, 1905.

The two electrodes are separated by a diaphragm of metal or other good electrical conductor, which consists of a number of ribs or channels of Y-shape so disposed that the upper rib forms a sealed joint with the rib immediately beneath it. The diaphragm is insulated from the electrodes.—R. S. H.

Electrolytic vat [for fused salts]. A. Lambert. Fr. Pat. 365,423, April 19, 1906.

The vat is specially intended for the electrolyses of fused salts, and differs from the ordinary carbon-lined iron vessels in the following particulars: Blocks, *b*, of well-conducting carbon form a part of the base of the vat, these

blocks being in good contact with the terminals of the current and with the electrolyte, the object being to ensure good electrical conductivity, and consequently diminished loss of energy. The sides of the vat are lined with stamped carbon, *f*, and are provided with exterior protecting walls, *e*, to increase the thermal insulation.

(*B.*)—ELECTRO-METALLURGY.

Iron; Electrolytic deposition of —— from aqueous solutions of ferrous chloride and sulphate. A. Ryss and A. Bogomolny. Z. Elektrochem. 1906, **12**, 697—703.

The authors have sought the most favourable conditions for obtaining thick deposits of iron by electrolysis. Pure solutions of ferrous ammonium sulphate behave best when the solution contains 70 grms. of crystallised salt per litre of water; increase of temperature above that of the atmosphere is deleterious, and the current density at the cathode should not exceed 0·5 ampère per sq. dm. With ferrous chloride a solution containing 1 kilo. of the salt per litre of water, a temperature of 60° to 70° C., and a maximum current density of 0·4 ampère gives the most favourable results. The electrolyte is always somewhat dirty from the formation of ferric hydroxide, which is also harmful to the metal deposition. Additions of a mixture of sodium bicarbonate and magnesium sulphate to the above electrolytes give improved results. The authors specify the following as the most suitable conditions: A current density of 0·3 ampère per sq. dm., an electrolyte containing 200 grms. of pure ferrous chloride or 200 grms. of crystallised ferrous ammonium sulphate per litre of water; in each case with an addition of 50 grms. of magnesium sulphate and 5 grms. of sodium bicarbonate.—R. S. H.

Iron silicides; Formation of —— in the electric furnace. B. L. Vanzetti. Gaz. chim. ital., 1906, **36** [1], 498—513.

In the interior of the silicious mass obtained from an electric furnace in which coke, sand, and lime were heated together at a temperature of about 3000° C., the author found metallic buttons having the sp. gr. 5·76—6·20, a hardness of about 7 on Mohs' scale, and the composition, FeSi. The chemical characters of the substance point to its being a chemical individual, as also does the absence of magnetic properties. The 3 per cent. of iron in the state of ferric oxide in the coke, doubtless combines first with carbon, the latter being subsequently displaced by silicon formed by reduction of the silica present.

Similar experiments at a temperature higher than 3000° yielded masses varying in appearance and sp. gr. (3·96—5·54), and more readily acted on by reagents than the compound FeSi. One of the buttons thus obtained had a sp. gr. approximately equal to that of the compound, $FeSi_2$, but its composition did not correspond with this formula.

If there be present, besides iron, another element which has an affinity for silicon, the latter combines with the two metals in proportions governed by the reacting masses and by their affinities. In one case, for instance, when a little copper found its way into the furnace, the metallic globules formed had the greyish-yellow, crystalline appearance characteristic of copper silicide, the crystals of which were found, by microscopic examination, to be mixed with other crystalline forms. These globules reacted in the cold with dilute nitric acid (1:1), with evolution of dense, red fumes and deposition of gelatino silica. The copper was present in amount greater th that corresponding with the formula, Cu_2Si.—T. H. P

Palladium; Electrical resistance of ——. F. Fisch Ann. der Physik, 1906, **20**, 503—526. Science Abstrac 1906, **9A**, 481.

When hydrogen is occluded by a palladium wire, t electrical resistance of the latter rises abruptly at first after as much hydrogen has been absorbed as would thirty times the volume of the wire at atmospheric pressu the increase of resistance becomes proportional to t amount of hydrogen occluded, until 950 volumes have be absorbed, after which the rate of increase is retarded. a state of saturation, palladium contains about 1000 vol of occluded hydrogen; an increase in the quantity hydrogen above this limit produces no further increase resistance. The maximum increase of resistance 60 per cent. The resistance is proportional to the formul $a+bH$, where H is the number of volumes of hydrog absorbed, a is 1·0292, and b is 668×10^{-6}. When a pall dium wire absorbs hydrogen, it expands to the extent 2539×10^{-8} cm. per cm. and per vol. absorbed, until t saturation point is reached, after which the expansion relatively greater. When the occluded hydrogen expelled, the wire becomes shorter than it was originall but the original resistance is recovered exactly.—A. S.

Sodium chloride; Process of electrolysing —. E. Castel. Fr. Pat. 364,847, April 2, 1906.

The chlorine and hydrogen generated in the electrolysis of sodium chloride are led separately to the two electrodes of a gas cell in which they serve to generate an electric current. The current is applied to reduce the expenditure of energy incurred in the electrolysis of the sodium chloride. The hydrochloric acid formed in the gas cell is utilised for extracting roasted copper matte, and the cuprous chloride thus obtained, with addition of sodium chloride, is subsequently electrolysed for the winning of the copper.—R. S. H.

German Patents.

Metallic deposits; Process for the preparation of electrolytic —, *especially on wire, by the use of a tubular anode.* A. Grünbaum. Ger. Pat. 165,875, June 26, 1904.

The wire to be plated is suspended within the tubular anode in the loops of hook-shaped supports connected to the negative pole of the battery, whereby, it is claimed, short circuits are avoided, and the resistance of the wire is diminished.—A. S.

Aluminium articles; Process for the electrolytic coating of — *with tin.* Basse und Fischer, G.m.b.H. Ger. Pat. 169,310, Oct. 6, 1904.

The aluminium articles are first electrolytically coated with nickel, and afterwards with tin.—A. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 938.)

Fats; Enzymic hydrolysis of —. S. Fokin. Chem. Rev. Fett- u. Harz-Ind., 1906, **13**, 130—133; 163—166; 192—194; 219—221; 238—240. (This J., 1904, 259, 614, 1152.

From an analysis of the oils of the seeds of two of th

All the plants yet known to contain lipase are poisonous; yet not all the seeds of plants containing alkaloids are able to hydrolyse fats, notable exceptions being *Heliotropum europeum, Cynoglossum officinalis, Digitalis purpurea, Buxus sempervirens,* and *Abrus precatorius.* The hydrolysis apparently effected by the two last is to be attributed to the presence of bacteria and mould-fungi. All starch-containing seeds are believed to produce diastase on germinating, and analogy would suggest the production of lipase in oil-containing seeds; but this was not borne out by the results of experiments with the seeds of *Linaria bipartita,* or with linseed, poppy, or mustard seeds. As regards the effect of germination of seeds which undoubtedly produce the enzyme, the author confirms the conclusion of Hoyer (this J., 1904, 550) that it has no influence upon the enzymic activity of castor seeds. On the other hand, certain small seeds have their lipolytic power doubled or trebled by the process of germination. The stimulating effect was greatest with the smallest seeds (*Linaria marrocana*), and became less with the increase in size to *L. purpurea,* then to celandine seed, and finally to castor seed.

Celandine seed (Chelidonium majus).—The characteristic property of the seeds of this plant is that no addition of soluble acids is necessary, the acids in the seeds themselves being sufficient for the hydrolysis. Acids of any considerable degree of concentration (*e.g.*, $\frac{1}{4}$ normal) destroy the enzyme, as is also the case with castor seeds; but variations of 25 to 100 per cent. (on the weight of the oil) of acids of a concentration of $\frac{1}{25}$ to $\frac{1}{100}$ normal have only a slight influence upon the yield of free fatty acids, whereas in the case of castor seeds the influence of this factor is very great. The optimum for the proportion of water is also very different from that required by castor seeds. With the latter the maximum of hydrolysis to be reached with a proportion of 1 to 0·5 per cent. of seeds is 60 to 66 per cent. Only in one experiment in which the glycerol water was removed was a yield of 82·5 per cent. obtained. On the other hand, celandine seeds, used even in the proportion of 0·5 to 0·3 per cent., gave as much as 90 per cent. of free fatty acids, without this precaution being taken. The difference between the lipase in celandine seeds (and in those of *Linaria* plants) and the lipase in castor seeds is also shown by the following facts:—(1) Connstein, Hoyer, and Wartenberg (this J., 1902, 1541) hydrolysed butter fat by means of castor seeds to the extent of 67 per cent. of the theoretical amount; with celandine seeds 95·7 per cent. was easily obtained. (2) Cocoanut oil was hydrolysed to the extent of 91·6 per cent. by means of castor seeds, and the unattacked portion isolated and treated with celandine seeds (20 per cent.), which decomposed it to the extent of 92·6 per cent. Separate experiments showed that these seeds hydrolysed laurin to the extent of 91 per cent., and caprylin to the extent of 78·4 per cent. (3) The glyceride of sebacic acid was hydrolysed (73·7 per cent.) by celandine seeds, but not acted on at all by castor seeds. (4) Glycol esters of cotton-seed oil fatty acids were hydrolysed (86·3 per cent.) by celandine seeds, but not attacked by castor seeds. These results disprove the conclusion of Connstein,

Hoyer, and Wartenberg (*loc. cit.*) that lipase cannot hydrolyse the glycerides of lower fatty acids. The completeness of the reaction depends upon the action of the liberated fatty acids upon the enzyme and upon their solubility in water. It is noteworthy that the esters of polyvalent alcohols (glycol, mannitol, &c.) with fatty acids can be hydrolysed by the celandine enzyme, whereas the monovalent alcohols usually act as a poison upon it, this effect increasing with their solubility in water. The nature of the acid has a great influence, and glycerides of aromatic acids (*e.g.*, benzoic acid) are quite unacted upon by the enzyme. The seeds of the celandine contain from 400 to 500 times more lipase than is required to hydrolyse the whole of the oil they contain. One part of the seed is able to hydrolyse more than 180 parts of oil, and one part of the seed flour (completely freed from fat, but containing the husks) more than 300 parts of oil.

Castor seeds.—It was found that the reaction took place much more rapidly in working with large quantities. Thus 20 kilos. of oil were hydrolysed in 7½ days, whilst 30 grms. required 27 days. In working with solid fats the process is promoted by the gradual addition of a certain amount of petroleum spirit or other naphtha distillate. Thus ox-tallow treated with 10 per cent. of castor seeds yielded after this addition 94·4 per cent. of free fatty acids in a day; whilst lard with 8·3 per cent. of seeds gave 90·5 per cent. of fatty acids. Experiments on the use of different soluble acids showed that:—(1) A concentration above $\frac{1}{10}$ *N* checks the reaction or considerably weakens the enzyme. (2) Oxalic, caprylic, and caproic acids lead to a very slight hydrolysis. On the other hand, the two last promote the reaction if they are dissolved beforehand in the oil (to the extent of 7 per cent.). (3) Amino-acids, asparagin, &c., do not promote hydrolysis. (4) Hydrocyanic, phosphoric, and nitric acids destroy the enzyme, but hydrofluoric acid is not poisonous. (5) In the case of such weak solutions as $\frac{1}{10}$ to $\frac{1}{100}$ *N*, complete dissociation of the acid must be assumed, though Hoyer holds a contrary view. One part of castor seeds freed from husks can hydrolyse 125 parts of fat, and one part of the seed meal (freed from oil) 375 parts. If a suitable fat, *e.g.*, olive oil, be used for the hydrolysis, the liberated fatty acids form a thick emulsion with water, and it is then hardly necessary to use mechanical means to promote the action of the enzyme. The products of the reaction need a thorough purification from impurities. The fatty acids can be freed from the seed-pulp without much difficulty by mechanical means, but the purification of the glycerol is much more difficult. A certain proportion of impurities from the seeds can be precipitated by means of lime or baryta water, or by basic lead acetate or tannin solution, but no satisfactory method has yet been devised for the separation of the remainder. The ordinary precipitants for proteids and alkaloids give no precipitate with the crude glycerin.

From several experimental determinations, the author concludes that the reaction with lipase is not reversible. One experiment on a large scale, in which 1 per cent. of castor seeds was used with 20 kilos. of oil, showed that the reaction was greatly accelerated by removing the glycerol water and replacing it by fresh acidified water. The liberated fatty acids have also an influence on the process, which is promoted by their removal. By repeated treatment the yield from different oils and fats in the author's experiments was, on the average, as high as 99 per cent. In certain cases there was a decrease in the proportion of free fatty acids, but this was attributed to combination of these acids with certain basic decomposition products of the proteids of the seeds. Wilhelmy's general formula for catalytic reactions—

$$\frac{1}{t} \mathrm{Lg} \frac{A}{A-x} = K$$

also holds good for the action of lipase, provided that the amounts of the substances used in the experiments are large enough to check the influence of external conditions upon the reaction. (See also this J., 1903, 639, 873, 1094, 1137.)—C. A. M.

Fats from refuse material. A. Lb. Chem.-Zeit., 1906, 30, 935—936.

Fats from leather refuse.—The cuttings or shavings of leather from tanneries and boot factories often contain considerable amounts of fat, introduced during the manufacturing processes, and capable of being recovered by extraction with petroleum spirit, leaving a nitrogenous residue suitable for working up into manure. There is considerable variation in the proportion of fat in different kinds of leather. Thus sole leather is practically free from fat, whilst upper-leather contains from 8 to 28 per cent., the amount in horse-skin being less than that in calf-skin "Whitening" shavings contain up to 35 or 40 per cent. of fat, which is lighter in colour, richer in stearine, and has less unsaponifiable matter than the fat from upper-leather. Thus the following results were obtained with different samples:—

	Saponification value.	Unsaponifiable matter.	Solidification point of fatty acids.
		per cent.	° C.
Fat from—			
"Whitening" shavings	185—188	up to 5	35—36
Upper-leather ,, .	139—140	,, 30	29—30

Since the extraction of the fat from the fine whitening shavings by themselves is very difficult, whilst the upper-leather yields an inferior fat, it is customary to mix the cuttings. Hence different "leather-extraction fats," as the author terms these products, to distinguish them from *dégras*, have similar properties, notwithstanding their various origin. They are dark brown or black, have a characteristic tan-like odour, and are solid at the ordinary temperature. They invariably contain a large proportion of unsaponifiable matter, and a considerable amount of free fatty acids. Filtered samples gave the following results:—Acid value, 85·7 and 73·7; saponification value (nine samples), 165 to 177·4; glycerol, 4·61 and 5·3 per cent.; unsaponifiable matter (seven), 11·1 to 15·0; and iodine value (one), 62·3. These fats yield dark-coloured soaps, the value of which is further reduced by the large amount of unsaponifiable matter. They form emulsions with water, and to separate the fat again it is necessary to treat the mixture for several hours with sulphuric acid and common salt at 96° C., and then to allow it to stand for 12 hours. The water can also be removed, all but about 3 or 4 per cent., by means of centrifugal force. A sample, of a light-yellow colour, contained 24 per cent. of water, 0·15 per cent. of ash, 11·40 per cent. of unsaponifiable matter, and 64·45 per cent. of saponifiable fat. The dark colour of leather-extraction fats is scarcely improved by even long-continued bleaching, and hence they are usually added to other fats (preferably bone-fat containing 97 to 98 per cent. of fat), in the proportion of 10 to 15 per cent. The addition is easily detected by the odour, but is not always clearly indicated by analysis, though the proportion of unsaponifiable matter is raised.

Distillation of the fatty acids of leather-extraction fat gives light yellow products suitable for the stearin and soap industries. They contain more stearin than the original fats, whilst the amount of unsaponifiable matter remains unaltered. A commercial sample had a saponification value of 144 and solidification point of 34° C., and contained 28 per cent. of unsaponifiable matter. A second sample contained 13·5 per cent. of unsaponifiable matter.

Fats from wool refuse.—The waste fragments from the spinning and weaving of wool contain a large amount of the fat used in lubricating the wool. The amount ranged from 12 to 27 per cent. in the author's samples. "Wool-extraction fats" vary widely in composition. They are black, fluid or semi-solid, contain a large proportion of unsaponifiable matter, and have a characteristic odour. The author obtained saponification values of 100 to 168, and from 14 to 45 per cent. of unsaponifiable matter. A typical sample gave the following results:—Acid value, 76; saponification value, 110; iodine value, 49; unsaponifiable matter (mineral oil), 43 per cent.; neutralisation value of fatty acids, 193; and iodine value of fatty acids, 88. The fat was therefore judged to consist of 40 per cent. of free fatty acids (claim), 17 per cent. of neutral fat, and 43 per cent. of mineral oil. Such

products can, at best, only be used for oiling wool again, or in the manufacture of inferior articles.

"*Wool-fat press-cake*"—These press-cakes contain from 16 to 22 per cent. of wool-fat, and 2 to 3 per cent. of nitrogen. The extracted fat can be utilised in the same way as ordinary wool-fat.—C. A. M.

Sesamé oil; Colour reactions of ——. P. Soltsien. Chem. Rev. Fett- u. Harz- Ind., 1906, **13**, 138.

Additional evidence in support of the conclusion that the furfural and tin reactions are not due to one and the same substance in sesamé oil is furnished by the author's experiments. Although the two substances can be separated from the oil by treatment with 90 per cent. alcohol, yet a thorough extraction with hydrochloric acid (sp. gr. 1·125) removes the substance that reacts with furfural, whilst the residual oil still gives an intense tin reaction. The latter reaction is also quite independent of Bishop's reaction, so that even when a sesamé oil no longer gives the furfural or Bishop's reaction, there is still a possibility of identifying it by means of the tin reaction. Varnishes; Theory of ——. A. Tixier. Monit. Scient., 1906, **20**, 726—730. (See also this J., 1904, 670.)

It is impossible to assign (as Coffignier does) a fixed melting point to a gum-resin; the melting point is greatly influenced by the mode of heating and even by the shape of the containing vessel; and although it has been maintained by Violette and others that a copal is not rendered soluble by heating until it has undergone a loss of 25 per cent. of its weight, the author has shown that by fusing in such a manner as to retain part of the volatile products, the loss need not exceed 10 per cent. The method for estimating the oil in a varnish (Coffignier) is open to serious objections. A layer of the varnish is allowed to dry on a glass plate, the film is extracted with amyl alcohol, and the insoluble residue is assumed to be linoxyn, the numbers obtained being made to agree with the known weight of oil by assuming a constant absorption of 6 per cent. of oxygen. The author's experiments show that linseed oil may absorb from 5 to 18 per cent. of oxygen whilst drying, so that no constant can be assumed; also that, contrary to the statement of Coffignier, the product obtained as above does not exhibit the properties of linoxyn.—M. J. S.

English Patent.

Turpentine; Treating —— to render it uninflammable. G. H. Harrison, Stourbridge. Eng. Pat. 21,954, Oct. 28, 1905.

The treatment consists in mixing turpentine with about 20 per cent. of carbon tetrachloride.—A. S.

French Patent.

Turpentine substitute; Preparation of a ——. A. Pollet. First Addition, dated April 12, 1906, to Fr. Pat. 354,425, May 20, 1905 (this J., 1905, 1118).

The turpentine substitute prepared according to the process described in the main patent, by mixing turpentine with rectified petroleum, is mixed with sufficient carbon tetrachloride to bring the specific gravity of the product up to 0·860. It is stated that the carbon tetrachloride destroys the characteristic odour and bluish tint of the petroleum.—A. S.

(*C*.)—INDIA-RUBBER, &c.

India-rubber; Influence of the resin-content on the combined sulphur in ——. R. Ditmar and A. Wagner. Gummi-Zeit., 1906, **20**, 1280—1282. (See this J., 1906, 769.)

In connection with the experiments of R. Ditmar on the vulcanisation of rubber with approximately constant proportions of sulphur and rising proportions of resin, the authors have determined the free and combined sulphur in the specimens in question. The free sulphur is found to increase from 1·6 per cent. to 2·4 per cent. as the resin increases from 5 to 23 per cent. This increase, together with the fact that the resin extracted by acetone was decidedly less than that originally added, is taken to prove that india-rubber resin is itself capable of vulcanisation with formation of products insoluble in acetone.—W. A. C.

French Patents.

Antimony compounds for use as pigments, &c.; Process for the preparation of ——. E. Chatillon. First Addition, dated April 19, 1906, to Fr. Pat. 353,565, April 20, 1905 (this J., 1905, 1023).

By adding suitable proportions of sulphur-containing substances to the charge of antimony ore, and adjusting the amount of alkaline-earth compounds added to the product, the process described in the main patent is modified so as to obtain antimony pigments mixed with free sulphur and lime or baryta, for use in the vulcanisation of rubber.—A. S.

Benzene and other volatile products evolved in certain industrial operations [Waterproofing with rubber]; Process and apparatus for the recovery of ——. A. E. Vincent. Fr. Pat. 361,603, July 3, 1906.

The patent relates especially to a process and apparatus for recovering the vapours of benzene, toluene, &c., evolved in the drying of fabrics coated with rubber solution. The drying table is enclosed in a closed bell,

into which hot air from a superheater is forced. The hot air takes up the vapours of the volatile solvent, and carries them along through a heat interchanger to one or more condensers, where the benzene, &c., is deposited. The cold air is led back to the heat interchanger, where it serves to cool a further quantity of hot air laden with benzene vapour; it then passes through one or more superheaters, back to the closed bell. The circulation of the air is effected by means of a pump or fan.—A. S.

Beetroots; Progress in methods of extraction of juice from ——. H. Claassen. Sixth Internat. Congr. Appl. Chem., Rome, 1906; Z. Ver. deut. Zuckerind., 1906, 805—809.

To ensure a higher degree of purity of diffusion juice, either the dissolved non-sugar in the cell juice must be rendered insoluble and thus retained in the beet slices, or solution of solid non-sugar must be avoided. In order to render non-sugar insoluble (*i.e.*, to coagulate albuminoid matter), the beetroot slices are either heated in steam or hot air to about 75° C. before extraction, or they are brought to the same temperature immediately on contact with the juice. The author points out, however, that juice does not begin to diffuse through the cell walls of the beetroot until a temperature of 55° C. has been attained, and that in the ordinary diffusion process not more than 5—10 minutes is required on the average to raise the temperature from 55° to 75° C. During this period only a small quantity of sugar, and very little albumin, pass into solution. Moreover, it has not been proved that the process of first heating the slices to 75° C. gives dry fodder slices containing a greater proportion of the total albumin content of the beetroot than that contained in the slices obtained by the ordinary diffusion process. Hence the author considers it preferable to work in such a manner that the amount of solid non-sugar dissolved is reduced to a minimum. Of the solid, more or less soluble non-sugar, *e.g.*, pectin substances, organic calcium and potassium salts, the amount dissolved increases with the temperature and dilution of the extracting liquor and with the duration of the extraction. Hence the purest juice is obtained by Steffen's original steeping process (heating the ground beetroot with undiluted juice), but this method presents the disadvantage that the sugar is not thoroughly extracted from the root. Instead of the beetroot juice, the author recommends the use of the diffusion waste waters. (For details of this process see this J., 1906, 327.)—L. E.

Maltodextrin-γ, an intermediate product of the hydrolysis of starch by diastase. C. Rheinfels. XVII., page 998.

Sachs-Le Docte process for sugar analysis; Further remarks on the ——. A. Le Docte. XXIII., page 1010.

Sugar industry of Belgium. Chamb. of Comm. J., Oct., 1906. [T.R.]

THERE are in Belgium about 125 factories and a large number of refineries. The sugar industry is one of those for which the country itself can produce almost all the requisite raw materials. Only the factories on the frontiers import beetroots from Holland and France. This importation amounted to 317,173 tons in 1905, compared with 125,572 tons in 1904. Belgium consumes nearly 20 per cent. of the sugar produced. The exports amounted in 1905 to 94,225 tons of raw beet-sugar, compared with 130,031 tons in 1904, and 43,714 tons of refined sugar in 1905, against 54,922 tons exported during the preceding year. The production of the last sugar crop in Belgium is considered to be 25 per cent. better than that of the year 1904. This increased production results from the extension of the area under cultivation, and partly also

from an increased yield per hectare. The percentage of sugar in the roots was equal to that obtained in the previous year. However, last season ended with losses on the part of most of the factories, and the sugar makers propose to combine to lower the purchase price of beet-roots during next season.

ENGLISH PATENT.

Dextrine; Apparatus for moistening ——. W. H. Uhland, Ges. m.b.H., Leipzig-Gohlis, Germany. Eng. Pat. 14,535, July 23, 1906. Under Int. Conv., July 21, 1905.

Fertiliser; Dry —— from by-products or residues from sugar works. E. Lallemant. Fr. Pat. 365,448, April 20, 1906. XV., page 997.

Starch which swells up in water and gelatinises; Method of preparing ——. J. Kantorowicz. Fr. Pat. 365,834, May 2, 1906.

THE starch is stirred into a concentrated solution of an alkali salt (for example, sodium sulphate), with which it does not gelatinise, and is then treated with a solution of caustic alkali and of the same alkali salt as already mentioned. At the end of ten minutes the saline solution is expelled by the aid of a press, and the starch is dried and pulverised. The alkali may be previously neutralised by an acid, or converted into an alkali salt by the addition of a salt of ammonium, magnesium, or calcium. A typical formula for the treatment is: starch, 1000 parts; caustic soda (35° B.), 40; concentrated solution of sodium sulphate, 100 parts.—C. S.

Barleys; Determination of proportion of husks in exhibition ——. A. Cluss and J. Schmidt. Woch. f. Brau., 1906, **23**, 480—481.

IN connection with the valuation of the coarseness and fineness of the husks by expert judges at an exhibition of barley, the authors have determined the proportion of husks by two chemical methods, *viz.*: the sulphuric acid method, as used in Vienna, and Luff's method. The tests showed that Luff's method gave results corresponding in all respects with the opinions of the judges, but that the results of the sulphuric acid method differed to an extraordinary extent from the other valuations. The results of the Luff method were also in complete harmony with the determinations of "crude fibre," starch, and extract in the barley. The sulphuric acid process is therefore quite valueless, but, on the other hand, Luff's process is scarcely suitable for the valuation of large numbers of samples in a short time as in the case of exhibitions. The differences, also, between the results afforded by barleys of distinctly different degrees of fineness, are not sufficiently pronounced to form a basis for a convenient scale of valuation.—J. F. B.

Maltodextrin-γ, an intermediate product of the hydrolysis of starch by diastase. C. Rheinfels. Woch. f. Brau., 1906, **23**, 510—511.

MALTODEXTRIN-γ, was first obtained by Grüters from the products of hydrolysis of starch by oxalic acid (this J., 1904, 875). Its position in the series of starch degradation products lies intermediate between maltose and the maltodextrin-β of Ling and Baker (this J., 1897, 154), which is identical with the achroo-dextrin III. of Prior (this J., 1896, 915). The author has now shown that this maltodextrin-γ is also a product of diastatic hydrolysis, and he has isolated it from the mixture of conversion products obtained by the action of diastase on starch paste at a temperature of 70° C., saccharification being allowed to proceed until a red iodine reaction was no longer obtained. After an elaborate series of fractionations with mixtures of alcohol and water, a maltodextrin-γ fraction of about 12 grms. was obtained from 1 kilo. of starch. This maltodextrin-γ had the constants $[\alpha]_D$ = 167·7°, R = 60·1 per cent. of maltose. In other fractions not quite free from sugar, the quantity of maltose was roughly estimated by the osazone test, and the constants for the maltodextrin portion, corrected for maltose, worked out at $[\alpha]_D$ = 163°—167°, R = 58—62 per cent. of maltose. If instead of referring the constants to the total dry substance of the syrups, the calculations be based on the "dextrose equivalents," the above values for maltodextrin-γ become $[\alpha]_D$ = 170°—173°, R = 61—64 per cent., which are probably nearer the truth. The author's maltodextrin-γ was fermented by Frohberg yeast to the extent of 50 per cent., whereas the similar maltodextrin prepared by Grüters, by hydrolysis with oxalic acid, was only fermentable to the extent of 24 per cent.—J. F. B.

Alcoholic fermentation; The chemical mechanism of ——. III. E. Buchner and J. Meisenheimer. Ber., 1906, **39**, 3201—3218.

THE authors communicate further particulars on the fermentation of sugar effected by the expressed cell juice of bottom fermentation yeast. The question of the production of glycerol and succinic acid as by-products of cell-free fermentation was carefully studied by means of control determinations of the quantities of these bodies already present in the juice, the analytical methods being checked by the addition of known quantities. From the results the authors conclude that succinic acid is not formed in the course of the fermentation of sugar by yeast cell-juice, but that glycerol is produced in large quantities. In different experiments quantities of glycerol corresponding to 5·4—16·5 per cent. of the quantity of alcohol were found. The authors incline to the view that the glycerol is formed in some indirect manner from the sugar, especially since the quantity of sugar disappearing is always greater than the sum of the carbon dioxide and alcohol. This question of the credit and debit account of the sugar has been studied by the authors on similar lines to those previously followed by Harden and Young (this J., 1904, 450), with cell-juice from top fermentation yeast. These authors showed that a considerable proportion of the sugar which apparently disappears when determined according to its cupric-reducing power is really converted into a non-reducing polysaccharide, which can be redetermined as reducing sugar after hydrolysis by acid. This polysaccharide is apparently not glycogen, but is a product of the action of some reverting enzyme in the yeast juice. The results of the authors with juice from bottom fermentation yeast confirm those of Harden and Young. In making up the sugar accounts, the quantity of sugar originally present in the juice and the quantity remaining after fermentation were included. To these were added, on the one side, the quantity of sugar added to the juice, and, on the other side, the quantity of sugar corresponding to the alcohol and the carbon dioxide. The losses found when the residual sugars were determined by the direct reduction of Pavy's solution amounted to 24—42 per cent. of the total. But when the residual sugars were determined by Pavy's solution, after hydrolysis by acid, the losses only amounted to 2—11 per cent. of the total sugar. Hence the authors conclude that the presence of a reverting enzyme in the juice is established, the proportion of polysaccharide thereby produced being estimated at 6—19 per cent. Apart from this reversion, a portion of the sugar losses must be put down to the production of glycerol. An examination of the alcohol produced by the fermentation of sugar by yeast cell-juice yielded only minute traces (about 0·01 per cent.) of fusel oil.—J. F. B.

(Beer) Final attenuation; Determination of the —— within 24 hours. F. Schönfeld. Woch. f. Brau., 1906, **23**, 489—491.

THE ordinary methods of determining the final attenuation of worts take several days, the quickest method hitherto practised, namely, by using 2 per cent. of yeast, requiring 48 hours. This latter period can, however, be reduced to one-half by taking 10 per cent. of yeast, of good attenuating power, that has been well pressed. Flasks holding

400 c.c. are charged with 200 c.c. of wort and 10 per cent. of yeast, and are placed in a water-bath at a temperature of 25° C. This need not be exactly maintained, but 29°—30° C. will give results below the truth. The proportion of yeast given is found to be the most suitable, since it furnishes the same results in 24 hours as are obtained with 0·5 and 2 per cent. of yeast in a correspondingly longer time. On the other hand, 20 per cent. of yeast gives higher results, which are inaccurate owing to the formation of alcohol by the autofermentation of the yeast.—C. S.

Acetic acid fermentation. E. Buchner and R. Gaunt. Annalen, 1906, **349**, 140—184.

"ACETON-DAUER" preparations were made from acetifying bacteria obtained by skimming the films off various culture media infected with beer-vinegar bacteria. The nature of the medium and the conditions of cultivation appeared to have a considerable influence on the activity of the preparations obtained. Whereas those obtained from bacteria grown in beer dregs were almost devoid of formentative power, those prepared from bacteria cultivated in unhopped wort were fairly active. Cultivation of the bacteria at temperatures of 10°—22° C. had a favourable influence on the activity of the "dauer" preparations as compared with cultivation at 28° C. The manner of treating the living bacteria was also important; when the masses of bacteria were simply separated by the centrifugal, and treated direct in the wet state with acetone, the "dauer" preparations were not nearly so active as when the masses were drained on porous plates before treatment with acetone. On the other hand, the sterility of these latter preparations was not perfect, owing to the resistance of the semi-dry, leathery masses to the penetration of the acetone. Several experiments showed, however, that the error introduced by the presence of traces of living cells in the "dauer" preparations was quite negligible when toluene was added.

In carrying out the fermentations, the "dauer" preparations were rubbed to a paste with 2—4 per cent. alcohol, with the addition of chalk and 4 per cent. of toluene. The mixtures were then exposed in flasks to a current of sterilised air for three days at a temperature of 28° C. In all cases the quantity of acetic acid produced was corrected by the results of similar experiments carried out with preparations in which the enzymes had been destroyed by heat. The yields of acetic acid so obtained were not very large; the highest recorded was 4 per cent. of the quantity of "dauer" preparation (after the treatment with acetone, and before mixing with the alcohol, chalk and toluene) taken; in most cases the yield was much smaller, *viz.*, 0·5—2 per cent. The "dauer" preparations, like the living bacteria, were capable of oxidising propyl alcohol to propionic acid. The authors conclude that there is no longer any room for doubt that the acetifying bacteria owe their oxidising properties to the presence of an enzyme, an oxydase. Apparently all three forms of oxydase are secreted by the bacteria, *viz.*, oxygenase, peroxydase, and catalase. As in the case of the lactic bacteria, juices prepared by trituration and pressure were devoid of fermentative properties.—J. F. B.

Lactic acid fermentation. E. Buchner and J. Meisenheimer. Annalen, 1906, **349**, 125—139.

The authors have further extended their studies on the enzyme secreted by the lactic acid bacillus, *B. Delbrücki* (see this J., 1903, 374). The bacilli were cultivated in a mixture of unhopped beer wort and rye-malt wort containing about 20 per cent. of sugar. The wort was sown with pure cultures of *B. Delbrücki*, and was fermented at a temperature of 40°—50° C. for 8—10 days. The bacteria were then separated by means of a centrifugal apparatus, washed with water, and drained on clay plates. The preparations were treated with acetone and then with ether, and were finally dried *in vacuo*. In this way, "aceton-dauer" preparations of dry, dead bacteria cells were obtained, which were perfectly sterile, but which retained the enzymes in the active state. The fermentations were started by grinding 10 grms. of "dauer" preparation with 10 grms. of sand, 2·5 grms. of chalk, and 2·5 c.c. of water for about 10 minutes, and mixing the mass with a solution of 10 grms. of cane sugar in 40 c.c. of water. The mixtures were incubated at 43° C. for six days in presence of 2 c.c. of toluene; yield: 2·1 grms. of the lactate. Attempts to prepare an active "press-juice," in the same way as yeast "press-juice," failed, owing either to the insolubility of the enzyme or to the failure to break up the cells to a sufficient extent. The residue after trituration and pressure, when treated with acetone, gave a "dauer" preparation of unimpaired activity.

Both cane sugar and maltose were fermented by the lactic acid enzyme, and evidence was obtained that the preliminary hydrolysis of these bioses by inverting enzymes also secreted in the cells. The product in all cases consisted of inactive lactic acid, although the same bacteria in the living state produced *l*-lactic acid.—J. F. B.

Vinegar; Test for distinguishing between fermentation vinegar and wood ——. E. Schmidt. XXIII., page 1009.

Spirituous essences in the Cape of Good Hope; Marking of ——. Bd. of Trade J., Oct. 4, 1906. [T.R.]

THE present Customs Union Tariff provides that when medicinal and toilet preparations and essences, syrups, and tinctures contain more than 3 per cent of proof spirit, they shall be entered under item 36 B of the Tariff as spirits, and pay a duty of 20s. per imperial gallon.

It would greatly facilitate the work of the Customs Department, and assist importers, if this fact could be brought to the notice of manufacturers and suppliers of these articles, in order that they may take steps to always indicate on their invoices those preparations that contain spirit, and give the total quantity in gallons and fractions thereof of the liquid contents, as duty is not levied on the proof gallon under item 36 B of the Tariff.

ENGLISH PATENTS.

Wine must, beer, beetroot juice, and the like; Treatment of ——. E. Monti, Turin, Italy. Eng. Pat. 18,138, Sept. 7, 1905.

SEE Fr. Pat. 357,770 of 1905; this J., 1906, 113.—T. F. B.

Fusel oil and components of fusel oil; Process for making ——. F. Ehrlich, Berlin. Eng. Pat. 6640, March 20, 1906. Under Int. Conv., March 31, 1905.

THE process consists in subjecting hydrolysed or peptonised albuminous substances, or decomposition products of albumin rich in leucine, to the action of yeast in the presence of carbohydrates, such as molasses, potatoes, &c. Leucine yields isoamyl alcohol, and isoleucine gives *d*-amyl alcohol. The products of the fermentation are distilled, and the fusel oil separated from the distillate. (See this J., 1905, 683.)—W. P. S.

FRENCH PATENTS.

Diastatic malt extracts; Method of rendering —— durable by converting them into a solid state. Deutsche Diamalt Ges. m. b. H. Fr. Pat. 365,971, May 7, 1906.

THE concentrated liquid extract of diastase is mixed to a paste with the flour of malted grain, and moulded, the product having a higher diastatic power than the original extract.—C. S.

Brewing; Method of and plant for ——. H. Breker. Fr. Pat. 365,497, April 23, 1906.

CONTINUOUS mashing and the production of wort are effected in three principal vessels, two of which are exactly alike, and serve, each in turn, alternately for mashing and boiling the wort, whilst the third serves to filter the wort between these two operations, so that the only break in the continuity of the work is while any of the vessels is being cleaned out.—C. S.

Filter [for beer]. K. H. Loew. Fr. Pat. 365,582, April 24, 1906.

THE claims relate to an upright filter-press surrounded by a casing supported by trunnions on a frame, so that it can be inclined at any angle to permit access to the interior.

The inlet and outlet orifices form part of the casing, and are provided with flanges to which the supply and delivery pipes can be accurately attached. The cage or press is formed of sections to facilitate the assembling and taking apart of the filter, and the cover plate is arranged so that it can adjust itself to any irregularities of the filtering mass, and is provided with means, such as a pump or ram, by which it can be raised or lowered.—W. H. C.

Wood cellulose and similar products; Processes for converting —— into fermentable sugar for the manufacture of spirits or alcohol, or for other purposes. A. Classen. Fr. Pat. 365,595, Jan. 31, 1906.

See Ger. Pat. 161,644 of 1904; this J., 1905, 1078.—T. F. B.

Fusel oils and their components; Method of producing ——. A. Sultan and I. Stern. Fr. Pat. 365,619, March 23, 1906. Under Int. Conv. March 31, 1905.

Hydrolysed or peptonised albumin, or amino-acids, are treated with ferments (distillery yeast) in presence of carbohydrates (preferably in the form of distillery wort). The fusel oil produced in the fermentation is separated from the ethyl alcohol in the usual way. If desired, suitable salts may be added to the liquid to be fermented. (See Eng. Pat. 6640 of 1906; preceding these.)—C. S.

(*A.*)—FOODS.

Beef fat; Detection of —— in lard. P. Soltsien. Chem. Rev. Fett- u. Harz-Ind., 1906, **13**, 240—241.

Notwithstanding the fact that Kreis and Hafner (this J., 1904, 755) showed that the respective crystals had a different composition, the microscopic detection of beef fat in lard has been found uncertain by various observers. To the well-known objections to the method the author adds the further one that flat tabular crystals may also be obtained from beef fat. If 1 grm. of the fat be dissolved in 10 c.c. of ether, and the solution left at below 15° C., and the deposit of crystals mixed with paraffin oil, slightly pressed under the cover glass, and examined under the microscope, apparently only the usual tufts of needles will be present. The author asserts, however, that a second form of crystals, in platelets resembling those from lard "stearin," can be detected in places where the paraffin oil has not touched the glass, or has evaporated. These by-crystals can also be seen under the same conditions in the crystals deposited from a solution of lard in petroleum spirit. (See also Dunlop, this J., 1906, 458.)—C. A. M.

Standards of purity for food products in U.S.A. Bd. of Trade J., Sept. 27, 1906. [T.R.]

A circular has recently been issued by the U.S. Department of Agriculture, establishing the standards of purity required for certain food products. The standards established by this circular supersede, and are supplemental to those proclaimed in December, 1904, and March, 1906.

English Patents.

Foods; Process for preserving liquid ——. Société "Le Lait," Paris. Eng. Pat. 7936, April 2, 1906. Under Int. Conv., April 3, 1905.

The liquid to be preserved is heated and agitated in an atmosphere of oxygen under pressure, the heating being continued for 30 minutes, at a temperature of from 70° to 95° C.—W. P. S.

Food for infants or convalescent adults, and process of manufacturing the same. E. de Pass, London. From Société "Le Lait," Paris. Eng. Pat. 10,480, May 4, 1906.

See Fr. Pat. 361,595 of 1905; following these.—T. F. B.

Drying or condensing apparatus [Milk, &c.]. G. A. Kammermann, Glockenthal, Switzerland. Eng. Pat. 10,608, May 5, 1906. Under Int. Conv., May 9, 1905.

See Fr. Pat. 365,970 of 1906; following these.—T. F. B.

French Patents.

Margarine; Manufacture of ——. E. A. Pellerin. Fr. Pat. 361,614, July 7, 1905.

In the process described, the operation of mixing the fat and water, in the presence of an emulsifying agent, is stopped precisely at the moment when an emulsion of the fat in the aqueous liquid is obtained. The paste obtained is of finer texture than that exhibited by an emulsion in which the aqueous liquid is emulsified in the fatty matters. It is stated that the margarine thus prepared, has a taste more nearly approaching that of butter than one prepared by the reverse method of emulsification.—W. P. S.

Malted milk for use as infants' food; Process of making ——. E. Terrien. Fr. Pat. 361,595, Oct. 20, 1905.

Seventy grms. of rice- or wheat flour are added to a mixture consisting of one-third of a litre of milk and two-thirds of a litre of water. The mixture is heated to a temperature of 100° C. for 15 minutes, then cooled to 80° C., and treated with an infusion of malt; the latter is prepared by heating 20 grms. of crushed malt with a little water to a temperature of 60° C. for 15 minutes. After adding 50 grms. of sugar, the whole mixture is once more boiled. When cold, it is ready for use.—W. P. S.

Malted milk for use as infants' food; Process for making ——. Société "Le Lait." First Addition, dated April 9, 1906, to Fr. Pat. 361,595, Oct. 20, 1905. (See preceding Patent.)

The proportion of milk to water employed in the process described in the principal specification may be varied according to the use to which the food is put (infants, adults, invalids, &c.). The prepared article may also be preserved under pressure in an atmosphere of oxygen, sterilised, or evaporated to a syrup, or completely dried to form a powder.—W. P. S.

Condensing apparatus [Milk, &c.]; Process for removing the pellicle of condensed material detached from the exterior surface of the hollow rotary drying drums by the scrapers in ——. G. A. Kammermann. Fr. Pat. 365,970, May 7, 1906. Under Int. Conv., May 9, 1905.

A roller is placed parallel and close to the drum just below the point at which the pellicle is detached by the scraper. The roller is rotated by gearing in the opposite direction to that in which the drying drum revolves, and draws off the pellicle in a continuous manner, depositing it in a receptacle placed below. If preferred, two parallel rollers may be used, one being placed slightly below the other, and they may have an endless band of cloth passed round them to assist in gripping and removing the pellicle.—W. H. C.

Cereals, &c.; Treatment of —— to form a flour for bread-making. F. Braunbeck. Fr. Pat. 365,827, May 2, 1906.

Cereals, such as wheat, rye, barley, oats, rice, and maize, or peas, beans, &c., are heated with water, and then ground to a paste, which is dried on rollers heated to a temperature of from 100° to 200° C. The flaky product scraped off the rollers is ground to form a flour.—W. P. S.

(*B.*)—SANITATION; WATER PURIFICATION.

French Patent.

Water; Continuous process for the removal of sulphuric acid from ——. H. Reisert. Fr. Pat. 365,449, April 20, 1906.

The water is led from an upper reservoir into the bottom of a tank, which is divided into a number of compartments

400 c.c. are charged with 200 c.c. of wort and 10 per cent. of yeast, and are placed in a water-bath at a temperature of 25° C. This need not be exactly maintained, but 29°—30° C. will give results below the truth. The proportion of yeast given is found to be the most suitable, since it furnishes the same results in 24 hours as are obtained with 0·5 and 2 per cent. of yeast in a correspondingly longer time. On the other hand, 20 per cent. of yeast gives higher results, which are inaccurate owing to the formation of alcohol by the autofermentation of the yeast.—C. S.

Acetic acid fermentation. E. Buchner and R. Gaunt. Annalen, 1906, **349**, 140—184.

"ACETON-DAUER" preparations were made from acetifying bacteria obtained by skimming the films off various culture media infected with beer-vinegar bacteria. The nature of the medium and the conditions of cultivation appeared to have a considerable influence on the activity of the preparations obtained. Whereas those obtained from bacteria grown in beer dregs were almost devoid of formentative power, those prepared from bacteria cultivated in unhopped wort were fairly active. Cultivation of the bacteria at temperatures of 10°—22° C. had a favourable influence on the activity of the "dauer" preparations as compared with cultivation at 28° C. The manner of treating the living bacteria was also important; when the masses of bacteria were simply separated by the centrifugal, and treated direct in the wet state with acetone, the "dauer" preparations were not nearly so active as when the masses were drained on porous plates before treatment with acetone. The mixtures were then exposed in flasks to a current of sterilised air for three days at a temperature of 28° C. In all cases the quantity of acetic acid produced was corrected by the results of similar experiments carried out with preparations in which the enzymes had been destroyed by heat. The yields of acetic acid so obtained were not very large; the highest recorded was 4 per cent. of the quantity of "dauer" preparation (after the treatment with acetone, and before mixing with the alcohol, chalk and toluene) taken; in most cases the yield was much smaller, *viz.*, 0·5—2 per cent. The "dauer" preparations, like the living bacteria, were capable of oxidising propyl alcohol to propionic acid. The authors conclude that there is no longer any room for doubt that the acetifying bacteria owe their oxidising properties to the presence of an enzyme, an oxydase. Apparently all three forms of oxydase are secreted by the bacteria, *viz.*, oxygenase, peroxydase, and catalase. As in the case of the lactic bacteria, juices prepared by trituration and pressure were devoid of fermentative properties.—J. F. B.

Lactic acid fermentation. E. Buchner and J. Meisenheimer. Annalen, 1906, **349**, 125—139.

The authors have further extended their studies on the enzyme secreted by the lactic acid bacillus, *B. Delbrücki* (see this J., 1903, 374). The bacilli were cultivated in a mixture of unhopped beer wort and rye-malt wort containing about 20 per cent. of sugar. The wort was sown with pure cultures of *B. Delbrücki*, and was fermented at a temperature of 40°—50° C. for 8—10 days. The bacteria were then separated by means of a centrifugal apparatus, washed with water, and drained on clay plates. The preparations were treated with acetone and then with ether, and were finally dried *in vacuo*. In this way, "aceton-dauer" preparations of dry, dead bacteria cells were obtained, which were perfectly sterile, but which retained the enzymes in the active state. The fermentations were started by grinding 10 grms. of "dauer" preparation with 10 grms. of sand, 2·5 grms. of chalk, and 2·5 c.c. of water for about 10 minutes, and mixing the mass with a solution of 10 grms. of cane sugar in 40 c.c. of water. The mixtures were incubated at 43° C. for six days in presence of 2 c.c. of toluene; yield: 2·1 grms. of the lactate. Attempts to prepare an active "press-juice," in the same way as yeast "press-juice," failed, owing either to the insolubility of the enzyme or to the failure to break up the cells to a sufficient extent. The residue after trituration and pressure, when treated with acetone, gave a "dauer" preparation of unimpaired activity.

Both cane sugar and maltose were fermented by the lactic acid enzyme, and evidence was obtained that the preliminary hydrolysis of these bioses by inverting enzymes also secreted in the cells. The product in all cases consisted of inactive lactic acid, although the same bacteria in the living state produced *l*-lactic acid.—J. F. B.

Titanium; Reactions of —. H. Grossmann. Chem.-Zeit, 1906, **30**, 907.

The author has studied the behaviour of titanium chloride with organic acids and their salts. Potassium cyanide gives a black insoluble precipitate, which becomes gradually lighter in colour on standing, but more rapidly when heated, being eventually converted into titanic acid, a reaction which precludes the existence of titanium double cyanides, $R_3Ti(CN)_6$. Potassium ferrocyanide develops a reddish-brown precipitate, which after shaking for a short time assumes a permanent orange-yellow colour. Potassium ferricyanide gives a dark brown precipitate, becoming light green on standing. Sodium acetate changes the violet colour of titanium chloride to dark green, which appears brown by reflected light. On heating the solution, a basic acetate separates which oxidises slowly on exposure. Acetic and formic acids are without action; sodium formate gives a dark green solution, depositing a basic salt on heating, which rapidly oxidises to form titanic acid. Oxalic acid gives a reddish-brown solution, from which alcohol separates a precipitate. Gallic acid gives a similar solution and a brownish-red precipitate on boiling. Xanthate, salicylate, and succinate of sodium form yellow, yellowish-brown, and green precipitates respectively. Tartaric acid is without action, but in the presence of alkali hydroxide a dark blue solution is obtained. Sodium tartrate gives a yellowish-green precipitate soluble in an excess of the reagent. Citric acid behaves similarly to tartaric acid.

Camphor production of Japan. For. Off. Ann. Series, No. 3713. [T.R.]

Formosan camphor, though plentiful, grows to a great extent in places which are still practically inaccessible owing to the savage tribes who occupy the districts. In Japan, on the other hand, where there is no such artificial impediment, the supply is being gradually exhausted. Camphor is now obtained from the leaves of the tree as well as the bark; the former yield about 1½ per cent.

The amount of crude camphor produced in 1905 was:—

	lb.
Formosa	4,800,000
Japan	1,226,607
Total	6,026,607

Of this, 837,333 lb. were refined in Kobe and Osaka, and 400,000 lb. sold to native druggists for use in Japan. The refined drug was nearly all exported.

English Patents.

Dialkylbarbituric acids; Manufacture of ——. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 23,718, Nov. 17, 1905.

In Eng. Pat. 14,161 of 1905 (this J., 1905, 1188) the production of dialkylbarbituric acids by treating dialkylmalonyldiurethanes with sodium ethylate and alcohol is described; it is now found that this condensing agent may be replaced by other condensing agents, such as ammonia, alkalis, sulphuric acid, or organic bases, in aqueous or alcoholic solution. The condensation of dialkylmalonyl chlorides with urethanes to dialkylmalonyldiurethanes does not take place quantitatively, but other products are formed, all of which can, however, be converted into dialkylbarbituric acids by treatment with any of the above-mentioned condensing agents. It is not necessary to isolate the first condensation products, since these can, in the crude condition, be easily condensed to the pyrimidine ring as described.—T. F. B.

Salicylic acid derivative [*Cinnamylsalicylic acid*]; *Manufacture of a new* ——. H. S. Wellcome, London, H. A. D. Jowett and F. L. Pyman, Dartford. Eng. Pat. 7125, March 24, 1906.

Cinnamylsalicylic acid may be prepared by heating, to 100° C., equimolecular proportions of cinnamyl chloride and salicylic acid for about three hours; after recrystallisation, the acid has a m. pt. of 155° C. The methyl, ethyl, and other esters of cinnamylsalicylic acid are obtained in a similar manner from cinnamyl chloride and a salicylic ester. The salts of the acid with organic and inorganic bases, especially those with quinine and sodium hydroxide, are also claimed. All the foregoing compounds find application in medicine.—T. F. B.

Camphor from isoborneol; Manufacture of ——. G. B. Ellis, London. From Chem. Fabr. von Heyden, A. G., Radebeul, Saxony. Eng. Pat. 10,407, May 3, 1906.

See Fr. Pat. 365,974 of 1906; following these.—T.F.B.

French Patents.

Δ_1-Cyclogeranic acid; Process of making ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 361,637, July 19, 1905.

See U.S. Pat. 805,924 of 1905; this J., 1906, 39.—T. F. B.

Camphor from isoborneol; Preparation of ——. C. F. Boehringer und Soehne. Second Addition, dated April 24, 1906 (under Int. Conv., June 1, 1905), to Fr. Pat. 352,888, March 31, 1905.

In a previous patent (see this J., 1905, 249) the oxidation of isoborneol by means of chlorine was described. It is now found that camphor technically free from chlorine can be obtained by a similar process from borneol.

—F. Shdn.

Isoborneol esters; Direct process for preparing —— from hydrochloride or hydrobromide of pinene. Chem. Fabr. von Heyden Akt.-Ges. Fr. Pat. 365,814, May 1, 1906. Under Int. Conv., Sept. 4, 1905.

See Eng. Pat. 10,999 of 1906; this J., 1906, 714.—T. F. B.

Camphor from isoborneol; Preparation of ——. Chem. Fabr. von Heyden Akt.-Ges. Fr. Pat. 365,974, May 7, 1906.

Isoborneol can be oxidised to camphor in a satisfactory manner by nitric acid containing a small amount of nitrous acid. The nitric acid can be treated previously with a little sodium nitrite or some easily oxidisable substance. (See this J., 1905, 1188.)—F. Shdn.

Guaiacol, creosote, or their homologues or derivatives; Process for preparing new esters from ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 365,683, April 26, 1906. Under Int. Conv., May 5, 1905.

See U.S. Pats. 822,339 and 824,901 of 1906; this J., 1906, 653 and 827.—T. F. B.

400 c.c. are charged with 200 c.c. of wort and 10 per cent. of yeast, and are placed in a water-bath at a temperature of 25° C. This need not be exactly maintained, but 29°—30° C. will give results below the truth. The proportion of yeast given is found to be the most suitable, since it furnishes the same results in 24 hours as are obtained with 0·5 and 2 per cent. of yeast in a correspondingly longer time. On the other hand, 20 per cent. of yeast gives higher results, which are inaccurate owing to the formation of alcohol by the autofermentation of the yeast.—C. S.

Acetic acid fermentation. E. Buchner and R. Gaunt. Annalen, 1906, **349**, 140—184.

"ACETON-DAUER" preparations were made from acetifying bacteria obtained by skimming the films off various culture media infected with beer-vinegar bacteria. The nature of the medium and the conditions of cultivation appeared to have a considerable influence on the activity of the preparations obtained. Whereas those obtained from bacteria grown in beer dregs were almost devoid of formentative power, those prepared from bacteria cultivated in unhopped wort were fairly active. Cultivation of the bacteria at temperatures of 10°—22° C. had a favourable influence on the activity of the "dauer" preparations as compared with cultivation at 28° C. The manner of treating the living bacteria was also important; when the masses of bacteria were simply separated by the centrifugal, and treated direct in the wet state with acetone, the "dauer" preparations were not nearly so active as when the masses were drained on porous plates before treatment with acetone. On the other hand, the sterility of these latter preparations was not perfect, owing to the resistance of the semi-dry, leathery masses to the penetration of the acetone. Several experiments showed, however, that the error introduced by the presence of traces of living cells in the "dauer" preparations was quite negligible when toluene was added.

In carrying out the fermentations, the "dauer" preparations were rubbed to a paste with 2—4 per cent. alcohol, with the addition of chalk and 4 per cent. of toluene. The mixtures were then exposed in flasks to a current of sterilised air for three days at a temperature of 28° C. In all cases the quantity of acetic acid produced was corrected by the results of similar experiments carried out with preparations in which the enzymes had been destroyed by heat. The yields of acetic acid so obtained were not very large; the highest recorded was 4 per cent. of the quantity of "dauer" preparation (after the treatment with acetone, and before mixing with the alcohol, chalk and toluene) taken; in most cases the yield was much smaller, *viz.*, 0·5—2 per cent. The "dauer" preparations, like the living bacteria, were capable of oxidising propyl alcohol to propionic acid. The authors conclude that there is no longer any room for doubt that the acetifying bacteria owe their oxidising properties to the presence of an enzyme, an oxydase. Apparently all three forms of oxydase are secreted by the bacteria, *viz.*, oxygenase, peroxydase, and catalase. As in the case of the lactic bacteria, juices prepared by trituration and pressure were devoid of fermentative properties.—J. F. B.

Lactic acid fermentation. E. Buchner and J. Meisenheimer. Annalen, 1906, **349**, 125—139.

The authors have further extended their studies on the enzyme secreted by the lactic acid bacillus, *B. Delbrücki* (see this J., 1903, 374). The bacilli were cultivated in a mixture of unhopped beer wort and rye-malt wort containing about 20 per cent. of sugar. The wort was sown with pure cultures of *B. Delbrücki*, and was fermented at a temperature of 40°—50° C. for 8—10 days. The bacteria were then separated by means of a centrifugal apparatus, washed with water, and drained on clay plates. The preparations were treated with acetone and then with ether, and were finally dried *in vacuo*. In this way, "aceton-dauer" preparations of dry, dead bacteria cells were obtained, which were perfectly sterile, but which retained the enzymes in the active state. The fermentations were started by grinding 10 grms. of "dauer" preparation with 10 grms. of sand, 2·5 grms. of chalk, and 2·5 c.c. of water for about 10 minutes, and mixing the mass with a solution of 10 grms. of cane sugar in 40 c.c. of water. The mixtures were incubated at 43° C. for six days in presence of 2 c.c. of toluene; yield: 2·1 grms. of the lactate. Attempts to prepare an active "press-juice," in the same way as yeast "press-juice," failed, owing either to the insolubility of the enzyme or to the failure to break up the cells to a sufficient extent. The residue after trituration and pressure, when treated with acetone, gave a "dauer" preparation of unimpaired activity.

Both cane sugar and maltose were fermented by the lactic acid enzyme, and evidence was obtained that the preliminary hydrolysis of these bioses by inverting enzymes also secreted in the cells. The product in all cases consisted of inactive lactic acid, although the same bacteria in the living state produced *l*-lactic acid.—J. F. B.

Filter [for beer]. K. H. Loew. Fr. Pat. 365,582, April 24, 1906.

THE claims relate to an upright filter-press surrounded by a casing supported by trunnions on a frame, so that it can be inclined at any angle to permit access to the interior.

than is the case with any other explosive, being only 1·9 per cent. at a density of 0·45. With Norwegian ballistite, on the other hand, although the volume of methane at the commencement is only 0·04 per cent., at a density of 0·45, it is 11 per cent. As might be expected from the large quantity of methane found in the case of Norwegian ballistite, the volume of hydrogen falls from over 20 per cent. to about 9 per cent. In the case of Italian ballistite the hydrogen rises from about 8 per cent. to about 10 per cent. In both explosives the nitrogen is practically constant at about 12 and 16 per cent. respectively, but there is a very great difference as regards the water. In Norwegian ballistite the water is practically constant at 14 per cent., whilst in Italian ballistite, commencing at density 0·05 with a volume of 20 per cent., it falls at density 0·45 to about 24 per cent. No other explosive approaches Italian ballistite in respect to the large volume of aqueous vapour formed, especially at low densities. In the case of five of the explosives, there is, with increasing density, a very considerable decrease in the volume of the

permanent and total gases; but with Italian ballistite, throughout the range of the experiments there is hardly any change. In regard to the relation between the density of charge and the pressure developed by the explosion, some abnormal pressures have been obtained with some explosives at high densities, but these pressures are far above those with which artillerists are concerned. Fig. 2 gives these pressure curves. In order to determine whether these slight increments of pressure in the Norwegian ballistites, and the much more abnormal increments in Explosives II. and VI. at densities of 0·5 are real, or due to partial detonation, or to wave action on the crusher-gauge during explosion, the author has calculated for the whole of the explosives the value of the products (volume of gas multiplied by units of heat, water gaseous), because, supposing there to be no detonation or violent motion of the gases, the pressure on the walls of the explosive cylinder should be dependent, in a vessel impervious to heat, solely on the quantity of gas and on the amount of heat generated by the explosion. The results are shown on Fig. 3. These curves practically confirm the pressure-curves of explosives I., II., V., and VI., and they equally show that the abnormal pressures of II. and VI. at densities of 0·5 are not confirmed.

Temperature of explosion.—This was calculated by two different methods. Knowing the units of heat (water gaseous), generated by the explosion, and the specific heat of the gases, the temperature of explosion is given by the equation:

$$t = \frac{\text{grm. units of heat}}{\text{specific heat}} \quad (1).$$

From the known pressure at any given density and the pressure, p_o, when the volume of gas generated is reduced to 0° C. and 760 mm., we have the equation

$$t = \frac{p - p_o}{0{\cdot}00367 . p_o} \quad (2).$$

At low charge densities it has been found that the temperatures calculated by means of equation (1) are very much higher than those obtained by equation (2). The variation is clearly shown on referring to the accompanying figure (see p. 1004). It will be noted that for each explosive two temperature curves are given (see Fig. 1). Beginning at a density of 0·05, the upper curve, in each instance, embodies the temperatures as calculated by equation (1), the lower, those calculated by equation (2). Thus, beginning with equation (1), Italian ballistite, which shows the highest temperature, commences at the density of 0·05, with 4943° C., this temperature hardly varying at all till the density of 0·25 is reached, when it slowly but regularly increases to about 5000° C. at density 0·45. Cordite Mark I. commencing at 4742° C., with a very slight fall, is practically constant up to density 0·30, after which it rises rapidly to a temperature of 5065° C. at a density of 0·50. In the case of the temperatures given by equation (2), however, remarkable differences are met with. At the higher densities and pressures, there is generally a very fair agreement in the temperatures obtained from the two formulæ; but as the density and pressure diminish, the divergence becomes in all cases considerable, but is much greater with the explosives which develop very high temperatures, and which give rise to large percentages of carbon dioxide. The author's explanation of this divergence is as follows: The nascent gases are generated at temperatures approximately as given by equation (1), and by the upper curve of each explosive as shown in the figure. Under the low densities and pressures at the very high temperatures, the carbon dioxide and probably some water are partially dissociated, giving rise to the fall in temperature exhibited by the results obtained from equation (2) at low densities. The great difference between, for instance, Italian ballistite and Nitrocellulose R.R. at a density of 0·1 is due, first, to the difference of the temperature at which the nascent gases are generated, and secondly, to the proportion of carbon dioxide which is subject to dissociation. Formula (1) gives for Italian ballistite at density 0·1 a temperature of nearly 5000° C. while the percentage of carbon dioxide is 38·2. The same formula gives for the nitrocellulose, at the same density, a temperature of formation of 3200° C., whilst the percentage of carbon dioxide is only 19·45. The dissociation of carbon dioxide commences at about 1300° C., and the very much higher temperatures of formation of the gases of Italian ballistite, combined with its double percentage of carbon dioxide, appears to be sufficient to explain the results obtained with this explosive. If reference be made to the curves, it will be seen that whilst at density 0·1 there is, with Italian ballistite, a difference of about 1800° C. between the two formulæ, there is, with the nitrocellulose, a difference of only under 800° C. At the density of 0·45 the differences between the two formulæ are as follows: Italian ballistite, 150° C.; Cordite Mark I, 200° C.; Cordite MD, 320° C.; Norwegian ballistite (167), 250° C.; Norwegian ballistite (165), 130° C.; and nitrocellulose, 180° C. With Italian ballistite alone, at the density of 0·45, the temperature derived from equation (2) is lower than that derived from equation (1).—G. W. McD.

Explosives Ordinance in Belgium. Bd. of Trade J., Sept. 27, 1906. [T.R.]

The "Moniteur Belge" of August 3 publishes a Royal Decree modifying previous decrees and establishing new regulations relative to the production, storage, sale, and carriage of explosives. The "Moniteur" may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall Street, E.C.

English Patent.

Explosives for use in torpedoes and the like. O. Silberrad, London. Eng. Pat. 437, Jan. 6, 1906.

Secret document under Section 44, Patents, &c., Act, 1883.—T. F. B.

French Patent.

Explosives of great safety; Process for the manufacture of ——. F. Volpert. Fr. Pat. 365,709, April 27, 1906.

The safety explosives described are characterised by the addition to the explosive of mixtures of ammonium chloride or other salts of ammonium, with salts of acids of manganese, chromium, and chlorine, especially the permanganates, chromates, bichromates, chlorates, and perchlorates of fixed alkalis and alkaline-earths, in quantities equivalent to, or nearly equivalent to 0·5 per cent. of the explosive mixture. The salts of the metal acids may be replaced partially, by approximately equivalent quantities of metal nitrates, especially alkali and alkaline-earth nitrates. Or the additions of ammonium chloride, &c., may be made in quantities not approaching equivalence.—W. C. H.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 957.)

APPARATUS, &c.

French Patent.

Methane and other light gases; Apparatus for detecting the presence of —— in mines, and for indicating their quantity. J. McCutcheon. Fr. Pat. 365,441, April 20, 1906. Under Int. Conv., Dec. 1, 1905.

See Eng. Pat. 24,900 of 1905; this J., 1906, 954.—T. F. B.

INORGANIC—QUANTITATIVE.

Potassium; Separation and determination of —— by means of perchloric acid. Pisani. Nouveaux Remèdes, 1906. **22**. 250.

A WEIGHED quantity of mixed potassium and sodium salts is treated with excess of perchloric acid, and evaporated to dryness on the water-bath. The dried residue is heated over the naked flame to complete the conversion into perchlorates. Sodium perchlorate is then dissolved out by means of 36 per cent. alcohol, in which solvent potassium perchlorate is insoluble. The latter is thrown on a filter, washed with 36 per cent. alcohol, dissolved in water in a tared capsule, evaporated to dryness, and weighed. The alcoholic solution of sodium perchlorate is also evaporated, and the residue weighed separately.—J. O. B.

Phosphoric acid: Quantitative volatilisation of —— from its salts. P. Jannasch and E. Heimann. Ber., 1906, **39**, 2625—2628.

THE authors add to the phosphate (0·5 grm.) in a flask about 6—8 c.c. of a liquid formed by mixing 30 c.c. of saturated cane sugar syrup and 10 c.c. of sulphuric acid (1 vol. acid and 1 vol. water). The mixture is carefully heated in an open air bath, and a stream of air passed through the flask till carbonisation is complete, and the mass is dry. Then the flask is connected to a receiver, heated to the highest temperature the flask will bear, and a stream of chlorine passed through till no more condensable products come over. Oxygen is now substituted for chlorine till all carbon is burnt. After cooling, 3—4 c.c. of the acid sugar solution are added, and worked round the flask, and the whole process repeated. In this way, the authors have volatilised the phosphoric acid completely from ammonium and magnesium phosphates, and they are now working out the details of the process and its extension to other phosphates.—J. T. D.

Carbon in steel; New colorimeter for the determination of ——. C. H. White. Bull. Amer. Inst. Min. Eng., 1906, 743—748.

EQUAL weights of the steel under examination and of a standard steel are dissolved in equal volumes of solvent, the solutions are diluted to a definite volume, and poured into hollow glass wedges, as nearly as possible of equal size, and with the sides inclined at the same angle. These wedges are mounted in a box so that they can be moved vertically, up or down, and there is a narrow, horizontal slit in both the front and the back wall of the box, to allow of the direct passage of light through the wedges at one zone only. A graduated scale is mounted alongside each of the wedges. When the wedges are so adjusted that the colours are of equal intensity, the percentage of carbon in the steel under examination can be readily calculated from the ratio between the thickness of the two wedges at the illuminated zone, or between the distances of the thin ends of the wedges from this zone. Suppose, for example, the standard steel contains 0·3 per cent. of carbon, and after the wedges have been adjusted until the colours match, it is found that the scale on the side of the standard reads 72, and the scale of the other wedge reads 60; then the proportion (60:70 = 0·30:x) shows that the steel under examination contains $\frac{72 \times 0 \cdot 30}{60} = 0 \cdot 36$ per cent. of carbon.—A. S.

Copper; Electrolytic determination of ——. F. Foerster. Ber., 1906, **39**, 3029—3035.

USUALLY copper must be deposited from nitric acid solution, so that towards the end of the operation the evolution of hydrogen, and consequent pulverulent character of the last deposited copper, may be prevented. By working with a single accumulator, however, the E.M.F. (2·05 volts.) is so lessened that no hydrogen is evolved, even in a sulphuric acid solution, nor can salts of cadmium, cobalt, nickel, iron, or zinc be electrolysed, whilst copper sulphate, which requires a voltage of only 1·49, is easily decomposed. The author has thus obtained good separations of copper from these metals, using about 0·25 grm. of copper as sulphate in 100 c.c., acidified with 10 c.c. of 2 *N*-sulphuric acid, a Winkler's gauze cathode, and a spiral wire anode. About eight hours are required, however, for complete deposition; but this time can be shortened to an hour or an hour and a quarter, by working at 80° C. In this case, when deposition is complete (shown by the fall of the current from about 0·35 to 0·05 ampère, or by the cessation of oxygen-evolution at the anode), the electrodes are lifted gradually out of the bath, and washed as they rise, so that the hot acid and air shall not attack the deposited copper. Separations from nickel, cadmium, or zinc are easily effected in this way; but not more than 0·1 grm. of iron per 100 c.c. may be present, or its alternate oxidation and reduction interfere with the deposition of the copper. Nor may more than a few centigrammes of nitric acid be present. —J. T. D.

Lead; Electrolytic separation of —— from acetic acid solutions. R. C. Snowden. J. of Physical Chem., 1906, **10**, 500—501. Chem. Centr., 1906, **2**, 1021.

ON electrolysing lead acetate solutions under ordinary conditions, feathery crystals of lead are deposited, which do not adhere firmly to the cathode. If the cathode be rapidly rotated, however, then, just as in the case of silver nitrate solutions (this J., 1905, 896), adherent deposits are obtained. With the cathode rotating at 2500 revolutions per minute in a solution containing 1 grm-equivalent each of lead acetate and free acetic acid per litre, a current-density of up to 0·5 ampère per sq. dm. can be used, whilst, if 1 per cent. of gelatin be added to the electrolyte, satisfactory results can be obtained with a current-density three times as strong.—A. S.

ORGANIC—QUALITATIVE.

Dyestuffs; Recognition and discrimination of artificial organic ——. G. Gulinow. Z. Farben-Ind., 1906, **5**, 337—343.

FROM an investigation of the different schemes constructed for the identification and classification of organic dyestuffs (see Witt, Chem. Ind. **9**, 1; also this J., 1886, 249; Weingärtner, Chem.-Zeit., 1887, **11**, 135 and 165; also this J., 1887, 451; Green, this J., 1893, **3**, and 1905, 1034; and Rota, Chem.-Zeit., 1898, **22**, 437; also this J., 1898, 798), the author concludes that the most satisfactory method of analysis is that based on the reduction of the dyestuff with either zinc dust in acid or alkaline solution, or stannous chloride and hydrochloric acid. In applying this reaction to dyestuffs generally, the behaviour with other reducing agents has been studied, the results of which are contained in the subjoined tables. Thus, zinc dust in neutral solution and hydrosulphite N.F. have been employed with advantage in determining to what chemical group a dyestuff belongs (*e.g.*, triphenylmethane derivatives, see Table I), whilst to ascertain the chemical properties, the ether reaction was found to furnish useful information. In carrying out the new scheme of analysis, the unknown dyestuff is in the first place examined for the presence of a sulphur group. Some sulphur dyestuffs may be recognised by their physical properties, such as imperfect solubility and evolution of hydrogen sulphide, whilst others are completely soluble in water, fail to liberate hydrogen sulphide, or exhibit an alkaline reaction, and give a precipitate with tannin. As dyestuffs in the form of bisulphite compounds react with lead paper, a test for the presence of sulphurous anhydride should invariably be made. If the dyestuff does not belong to the sulphur or oxyketone groups, it is further investigated for solubility, and the solution reduced with zinc dust and hydrochloric acid. Should a precipitate be formed, the reduction is effected in alkaline solution. The reduced solution is filtered, and subjected to oxidation with persulphate, to ascertain whether the dyestuff can be regenerated.

TABLE I.

TABLE II.—(*continued*).

—D. B

Vinegar; Test for distinguishing between fermentation vinegar and wood ——. E. Schmidt. Z. angew. Chem., 1906, **19**, 1610—1612.

THE author describes two modifications of Rothenbach's test for the identification of vinegar produced by the fermentation of alcohol (Z. Unters. Nahr. u. Genussm., 1902, 817). These modifications are stated to make the test more delicate, so that it can be applied to mixtures of the two sorts of vinegar. One method, devised by Kraszewski, consists in making the vinegar alkaline by caustic soda, and then shaking out with amyl alcohol. The amyl alcohol is evaporated, the residue is dissolved in water, acidified by sulphuric acid, and tested with iodine solution. If the sample consisted of or contained fermentation vinegar, a precipitate or turbidity is produced after the addition of the iodine, and cooling. It is stated that the approximate proportion of fermentation vinegar can be judged by the result. The second method, proposed by the author, consists in distilling off 100 c.c. of the sample, and testing the residue with iodine. These methods depend on the presence in fermentation vinegars of by-products of bacterial life, which, being of the nature of alkaloids, give precipitates with iodine. Wood vinegars, made by diluting "vinegar essence," give no turbidity with iodine.—J. F. B.

Alypine; Distinctive reactions of ——. P. Lemaire. Rép. Pharm., 1906, **18**, 385—387.

WHEN warmed gently with strong cobalt nitrate solution, a few particles of alypine (benzoyltetramethyldiaminopentanol hydrochloride) give a fine blue colour; cocaine hydrochloride gives a similar colour. A solution of 0·05 grm. of alypine in 20 drops of water gives an almost immediate crystalline precipitate with 9 c.c. of 10 per cent. zinc chloride solution. Under similar conditions holocaine hydrochloride gives an immediate white precipitate which rapidly aggregates to oily droplets; cocaine hydrochloride, stovaine, and β-eucaine hydrochloride, are unaffected; subcutine slowly deposits a few needle-shaped crystals. When a particle of alypine is treated with 1 c.c. of sodium hypobromite reagent, a white precipitate is formed, which aggregates to oily drops. On warming, no reddish-brown colour is produced, such as is given by subcutine, nirvanine, holocaine hydrochloride, or orthoform. A one per cent. solution of alypine, when treated with two or three drops of 2 per cent. iron alum solution, does not give a violet colour, like subcutine or nirvanine, nor a red-brown colour, like orthoform.—J. O. B.

ORGANIC—QUANTITATIVE.

Indigo; Analysis of ——. C. Rawson. J. Soc. Dyers and Col., 1906, **22**, 306—307.

THE author criticises the paper by W. P. Bloxam (this J., 735), in which it is stated that the permanganate method of analysis is inaccurate. The author maintains, however, that this method as worked by himself and his colleagues gives reliable figures. The volumetric and the gravimetric "hyposulphite" processes recommended by the author in 1885 are two other reliable methods, and although the combined gravimetric and volumetric hyposulphite method involves somewhat long and tedious operations, the same objection applies to Bloxam's "tetrasulphonate" method.—J. C. C.

Tan liquors; New and accurate method for the determination of free acid in ——. A. W. Heppenstedt. J. Soc. Dyers and Col., 1906, **22**, 316. (See also this J., 1905, 1096.)

FIFTY c.c. of the liquor to be analysed are diluted to 500 c.c. To 200 c.c. are added 20 c.c. of a quinine solution made by dissolving 15 grms. of pure quinine in 110 c.c. of previously neutralised 95 per cent. alcohol and diluted with water to 200 c.c. After mixing thoroughly and filtering, the filtrate is titrated with *N*/10 caustic alkali, using phenolphthalein as indicator. The number of cubic centimètres used, multiplied by 0·066, gives the direct percentage of acid, reckoned as acetic acid, in the original liquor.—J. C. C.

Turkey-red oils; Analysis of ——. W. Herbig. Chem. Rev. Fett- u. Harz-Ind., 1906, **13**, 187—190; 211—213; 241—244.

IT is shown that decomposition of a Turkey-red oil with cold hydrochloric acid for the determination of the total fat gives results differing but little from those obtained on treatment with boiling hydrochloric acid. In order to obviate the confusion that is found in commerce with regard to the exact meaning of, *e.g.*, "50 per cent. Turkey-red oil," the author recommends that it shall be accepted that the percentage invariably refers to the percentage of total fat. The following method of determining this, in conjunction with a determination of the combined sulphuric acid, is stated to give closely concordant results: 10 grms. of the Turkey-red oil are heated in a flask with 50 c.c. of water until the fat has dissolved, and the liquid then treated with 25 c.c. of "dilute" hydrochloric acid, and boiled for three to five minutes. When cold, the contents of the flask are washed into a separating funnel

with water and ether, the amount of the latter being about 200 c.c., and the whole vigorously shaken. The aqueous layer is drawn off, and the ethereal solution washed with three successive portions of water, which takes from 30 minutes to one hour. The united aqueous liquids are heated to boiling, and after all ether has been expelled, the sulphuric acid is precipitated as barium sulphate. The bulk of the ethereal layer is distilled at a low temperature, the residue transferred to a weighed beaker, and the remainder of the ether allowed to evaporate spontaneously. The residue of fat is heated for one or two minutes over a free flame until bubbles cease to appear, and is then dried for 30 minutes at 105° C., and weighed.—C. A. M.

Beetroot analysis; Which is the best method for ——? F. Sachs. Z. Ver. deut. Zuckerind., 1906, 918—924.

On scientific grounds the method of alcoholic extraction for beetroot analysis is the best; owing, however, to the great care required in its execution, it can only be recommended for practical purposes as a means of occasional control of a simpler process. For the same reason the methods of cold and warm alcoholic digestion are unsuitable in cases where a large number of analyses is to be performed. The method of warm aqueous digestion also requires too much time and care; it is useful for purposes of control. The author recommends the following (Sachs-le Docte) process, a modification of the cold aqueous method, as being rapid and sufficiently exact. The beetroot is made into a very fine pulp by means of Keil and Dolle's conical beetroot borer or other similar instrument. After the pulp has been thoroughly mixed with the hand in order to remove any lumps which may have escaped grinding, 26 grms. (for German saccharimeters) are weighed into a tared metal beaker of about 250 c.c. capacity, which is provided with an india-rubber cover; 177 c.c. of water, containing 5—6 c.c. of lead acetate solution (of about 30° B.), are then added, and the mixture is thoroughly shaken several times. The solution is filtered, the filtrate treated with a few drops of acetic acid, and polarised in a 400 mm. tube. The reading gives the average content of sugar in the beetroot. For French polarimeters 32·58 grms. of pulp and 171·2 c.c. of water and lead acetate solution are employed, the observed reading being halved. In the case of polarimeters for which 20 grms. is the normal weight, 20 grms. of pulp and 182·3 c.c. of water and lead acetate solution are taken. The author quotes experiments which show that, provided the pulp is properly prepared, digestion is complete and practically instantaneous. He shows, also, that the error introduced by taking 177 c.c. of water in all cases (*i.e.*, with samples of varying sugar and juice content) is practically negligible.—L. E.

Sachs-le Docte process; Further remarks on the ——. A. Le Docte. Z. Ver. deut. Zuckerind., 1906, 924—931. (See preceding abstract.)

The author gives a detailed description of the Sachs-le Docte method for beetroot analysis, together with diagrams of the apparatus required.—L. E.

Formic acid; Determination of —— by means of permanganate. J. Klein. Ber., 1906, **39**, 2640—2641.

The author points out that in 1887 he published a method for this determination, in which the formic acid or formate was added to a known amount of boiling alkaline solution of permanganate of known strength. After reaction, excess of oxalic acid was added, then dilute sulphuric acid, and the oxalic acid in excess was finally determined by permanganate.—J. T. D.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 958.)

Metal acid anhydrides; Action of liquefied ammonia on ——. A. Rosenheim and F. Jacobsohn. Z. anorg. Chem., 1906, **50**, 297—308.

The authors have studied the action of liquefied ammonia on the acid anhydrides of chromium, molybdenum, tungsten, uranium, arsenic, vanadium, and antimony. In no cases were amino compounds produced, but in all cases where reactions took place, salts of imino-acids were obtained. Ammonium salts and, in some cases, lead and potassium salts of the following acids were prepared: Iminochromic acid, $NH{:}CrO(OH)_2$, iminomolybdic acid, $NH{:}MoO(OH)_2$, iminotungstic acid, $NH{:}WO(OH)_2$, and iminometa-arsenic acid, $NH{\cdot}O(AsO.OH)_2$. No definite compounds could be obtained by the action of liquefied ammonia on uranium, antimony, and vanadium compounds.—A. S.

Hydrogen sulphide; Liquid —— as a solvent. U. Antony and G. Magri. Gaz. chim. ital., 1905, **35**, [1], 206—226.

As a solvent liquefied hydrogen sulphide has somewhat similar properties to those of carbon bisulphide, alcohol, ether, and benzene; its ability to cause ionisation is far less marked than that of water and other strongly dissociating solvents. Electrically, it is non-conducting. It does not dissolve salts of strong bases, but non-metallic compounds are dissolved in it, giving conducting solutions. Solutions of iodine in liquefied hydrogen sulphide possess very considerable conductivity, those of phosphorus iodide are conducting to a lesser extent, whilst those of the haloid compounds of other non-metals show only moderate conductivity. Solutions of certain organic substances—for example, iodoform and tetramethylammonium iodide—yield solutions having conductivities which indicate that organic compounds may become ionised in liquefied hydrogen sulphide.—A. S.

New Books.

Technologie et Analyse Chimiques des Huiles, Graisses, et Cires. Par le Dr. J. Lewkowitsch, M.A., &c. Traduit de la troisième édition anglaise, spécialement revue et augmenté par l'Auteur, par Emile Bontoux, Directeur technique de la Société Anonyme de Savonnerie Marseillaise. Tome I. H. Dunot et E. Pinat, Editeurs, 49, Quai des Grands-Augustins; Paris, 1906. Price 20 fr.; bound 21.50 fr.

This, the first volume of the complete French edition of this work, is of 8vo size, and contains 564 pages of subject matter, with 53 illustrations. Additional matter is incorporated in this edition by the author, and some special French methods by the translator with the author's approval. (See also this J., 1904, 802, and 1905, 214).

Technologie der Fette und Oele. Handbuch der Gewinnung und Verarbeitung der Fette, Oele, und Wachsarten des Pflanzen- und Tierreichs. Unter Mitwirkung von G. Lutz, O. Heller, Felix Kessler, und anderen Fachmännern. Herausgegeben von Gustav Hefter, Director der Aktiengesellschaft zur Fabrikation vegetabilischer Oele, Triest. Erster Band. Gewinnung der Fette und Oele. Julius Springer's Verlag, Berlin. 1906. Price M. 20. Bound, M. 22.50.

8vo volume, containing 705 pages of subject matter with 346 illustrations, and 10 tables, followed by an alphabetical index of authors and subjects. The subject matter of Vol. I. is arranged according to the following scheme: I. General. Occurrence, Formation, and Uses of the Natural Oils, Fats, and Waxes II. The Constituents of Oils, Fats, and Waxes. III. Chemistry, Properties, and Behaviour of Oils, Fats, and Waxes. IV. Production and Further Working up of Oils and Fats Generally. V. Extraction of Vegetable Oils and Fats. VI. Extraction of Animal Oils and Fats. VII. Extraction of Waxes and Refuse Fats. VIII. Purification of Oils, Fats, and Waxes. (i.) Removal of Mechanical Impurities. (ii.) Removal of Albumins, &c. (iii.) Removal of free fatty acids. (iv.) Removal of colouring matters. (v.) Removal of odourous matters. (vi.) Methods for securing better preservation, improved flavour, &c. (vii.) Methods for raising the melting point or reducing the solidifying point of fats and oils, &c.

JOURNAL OF THE
Society of Chemical Industry.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

DECENNIAL INDEX, 1896—1905.

IMPORTANT NOTICE.

The Hon. Treasurer is prepared to receive subscriptions for the Decennial Index (1896—1905). The Authors' Names portion is now in the press and will be issued early in the new year; and the subject-matter portion will follow as soon as possible afterwards. The price is 10*s.* for the whole Index, or 11*s.* ($2.75) post free.

Copies of the Collective Index (1881—1895) may be had at the same price.

Cheques on members' own bankers, or money orders, payable at the G.P.O., London, should be made payable to Samuel Hall, and sent to the Hon. Treasurer, East London Soap Works, Bow, E., with the signed fly-leaf of a notice which will be sent out with the ordinary subscription notice, and to any others who make application for it.

SUBSCRIPTIONS OF MEMBERS ABROAD.

IMPORTANT NOTICE.

Members are reminded that the subscription of 25*s.* ($6.15) for 1907 should be sent so as to reach the Hon. Treasurer early in the New Year, so as to ensure continuity in the receipt of the Society's Journal.

For the greater convenience of members abroad, arrangements have been made whereby cheques on their own bankers, drawn in the usual way and in their own currency, will be accepted in payment of subscriptions. Cheques and money orders on G.P.O., London, should be made payable to Samuel Hall, and forwarded to him at Bow.

The return, whenever possible, of the fly-leaf attached to the subscription notice, is specially recommended as a means whereby the sender may be identified, and changes of address recorded, on which depends the safe receipt of the Journal.

Death.

Odling, Francis J., Prince's Bridge, Melbourne, Vic., Australia. Sept. 10.

Liverpool Section.

Meeting held at Liverpool on Wednesday, October 10, 1906.

DR. JAMES T. CONROY IN THE CHAIR.

THE CHEMICAL TRADE OF ENGLAND AND GERMANY—A COMPARISON.

BY JAMES T. CONROY, B.SC., PH.D.

The progress of chemical science and industry is a subject of interest to all of us, and to place on record the progress made and to further, as far as possible, the development of chemical industry are to be counted amongst the chief objects of our Society. In viewing the results attained it is not sufficient to consider merely from a purely scientific point of view how far the industry has advanced; it is further essential to take count of its growth from the commercial standpoint, to note alterations in volume of trade, the increase in earning-power, and the additional employment opened out for wage-earners. These strictly utilitarian points are perhaps the more important from a national point of view; they are points which ought to appeal to all members of the Society, and I thus propose in my address this evening to bring before you some facts and figures bearing on the subject I have got together during recent years. I choose this subject the more readily because I feel there is considerable lack of knowledge and much misconception with regard to many questions bearing on our trade in chemical and allied products, and because a study of the official returns of this country does not, unfortunately, afford much help in making our position clear. F. Evershed has already called attention (this J., 1903, 22, 398) to the unsatisfactory manner in which our Board of Trade returns—so far as regards chemical manufactures and products—are made up, and how insufficient they appear when compared with the corresponding returns made in Germany and France and, I might add, in most other countries. On this occasion improvement was foreshadowed, and I am glad to say that during the last two years a number of additions have been made to the official lists. Nevertheless, even our improved lists leave much to be desired. The lists are not compiled on any scientific basis; a very large proportion of the returns is comprised under the heading "——unenumerated," and our system of classification renders it a matter of extreme difficulty, if not impossibility, to make a comparison of our business with that of other countries. This difficulty of making proper comparison was strongly impressed upon me when giving evidence some two years ago before the Departmental Committee on Industrial Alcohol, when Sir Henry Primrose, the Chairman of the Committee, said that from our Statements of Trade he did "not see any figures that would seem to make up £3,170,000, or anything like that amount, under the head of chemicals." The figure £3,170,000 was the value, given in my *précis* of evidence, of our then imports of chemicals from Germany. As a matter of fact, our own Board of Trade figures showed at this time a value of only some £600,000, of which bleaching powder, saltpetre, and soda compounds contributed 20 per cent., and "other chemicals" the remaining 80 per cent. This sum, however, does not include medicines and aniline dyes, alizarin, indigo, &c., which are grouped with chemical products in Germany and also in this country in making up the annual returns relating to chemical industry. If now we turn to the Board of Trade list, so as to include aniline dyes, what do we find? Out of a total of—in round figures—£1,000,000, we find Germany credited with less than one-tenth; the bulk is shown as coming from Holland. Our returns are here transparently at fault, and in this item investigation by the Board of Trade has substantially confirmed the accuracy of the German figures.

With this corroboration I feel considerable confidence in taking the German figures as correct, and in much that follows I have gone to German sources for my information. These German figures will not, of course, give values representing the trade of this country except in so far as they relate to trade between Germany and ourselves. They will, however, tell us this, and do so in a clear and detailed fashion. They will further enable us to learn something of the German method of classification and better help us, after consideration of the German chemical trade as a whole, to grasp our own position. Dealing with the figures in this order will, I hope, afford that comparison with what others are doing which is often the surest guide to our own progress, and, more especially, to our own possibilities of progress.

Trade in chemicals between England and Germany.—With this introduction I will draw your attention to Diagram 1., which represents the trade between this country and Germany over a period of 15 years in all substances included in the German official list under "Drogen, Apotheken, und Farbwaaren." It will, I think, be a revelation to most of you. In 1890–92 the interchange of chemical products between the two countries was equal, each exporting to and importing from the other goods of the value of some £2,400,000 annually. To-day our exports to Germany stand at less than £1,200,000, whilst their exports to us have exceeded £3,500,000. The picture is startling and disquieting, and did the course of our trade with Germany represent that with the rest of the world our position as chemical manufacturers would be serious indeed. Fortunately, it does not. On the whole our industry is progressing; whether the progress is what it ought to be remains to be seen. To this point I will return later; for the present I propose to trace to some considerable extent the nature of the dealings between the two countries. For this purpose I have tabulated (Table I) the exports and imports in various chemicals for the two years 1895 and 1905, choosing these years so as to give the latest available information as to our present trade. I may say that figures for any other two years, or any series of years from 1892 onwards, would tell the same tale, possibly varying slightly for individual items, but not in any way affecting the general view. The diagram is, I feel sure, sufficient proof of this. In preparing the table, I have followed the German system of classification. In this system, the various materials are divided into the two main divisions: raw materials, and manufactured products. These main divisions are further subdivided into six classes, or groups, as follows (the values in parenthesis give the number of headings appearing in each group in 1895 and 1905 respectively):—

	No. of Headings.
I.—*Raw materials.*	
A.—Raw materials for the chemical industry	(12—14)
B.—Drugs for medicinal purposes and perfumery	(15)
C. Resins and leather waste ..	(6—7)
D. Ferments and fining materials ..	(5—4)
E. Crude colour materials	(11—12)
F.—Tanning materials	(8—10)
II.—*Manufactured articles.*	
A.—Elements, bases, acids, and salts..	(60—66)
B.—Ethers and essential oils, medicines, and perfumery..	(18—22)
C.—Resin oils, varnishes, lacquers, &c.	(9)
D.—Explosives and matches	(7)
E.—Pitch, tar, and tar products ..	(9)
F.—Writing and drawing materials and colours	(29—34)

On the whole, the classification is sound and good; exception may, however, be taken to the inclusion of certain items appearing in some of the groups, and for such instances I would refer to Mr. Evershed's paper. The total import and export figures under the above headings somewhat exceed the values given in the various yearly returns from which Diagram I. has been prepared, inasmuch as they include, in addition to Drog., Apoth., and Farbwaaren, certain minerals and ores, such as pyrites, manganese, &c., and also tar, pitch, resins, and asphalt.

Examining these figures in detail, we see that, as might be expected, the international trade in raw materials forms but a small percentage of the total interchange. The period covered is not long enough to show the great changes which have taken place in this branch. These changes are more particularly noticeable in quinine bark, galls, and gums, and are clearly shown in the Appendix to Mr. Tyrer's presidential address (this J., 1896, 495). London, once the chief market for quinine bark, lost this distinction many years ago, and, in the matter of galls, I read only a few months ago that, instead of buying in London or Hamburg, the consumers are to-day purchasing direct in Shanghai. Our own returns bear this out; our export of galls in 1905 amounting to only £13,197, as against £37,632 in 1904 and an average of well over £50,000 for previous years. In regard to gums, whilst the German purchases have more than doubled during the last ten years, the quantity bought from us has fallen to about one-half, the bulk now being drawn direct from British East Indies and Egypt. Of course our export business in these articles was, so to say, merely in the nature of brokerage, but the changes are unsatisfactory, inasmuch as they tend to lessen our control over and touch with the respective markets, and also to diminish our oversea trade.

Passing now to manufactured articles, we find in Class A that, apart from "unenumerated" products, potassium compounds account for, say, one-half the German exports to this country, having risen from £266,000 in 1895 to £350,000 in 1905. The potassium salts industry is, however, practically a German monopoly, and our increased imports of these salts should be all to our benefit, being to a large extent—one might almost say—in the nature of raw material.

As regards soda and bleaching powder, the position is not so satisfactory, for whereas in 1895 there was a balance in our favour, there is now a much larger balance in favour of Germany. This is, no doubt, mainly due to the introduction of electrolytic methods in the manufacture of alkali and bleach, and to the immense impetus which such introduction has given to the working up in Germany of potassium chloride for the production of caustic potash. In this connection, some interesting figures were published in the early part of last year by Hasenclever, who stated that, of the 260,000 tons of bleaching powder representing the world's production, one-half was now produced electrolytically. The total bleach production in Germany now exceeds 60,000 tons per annum, and of this 65 per cent. is prepared electrolytically, and in the main from potassium chloride.

Amongst other chemicals in Class A, the group comprising benzoic acid, citric acid, tartaric acid, tannic acid, salicylic acid, and oxalic acid represents an important and growing item, having risen from £123,300 in 1895 to £140,000 in 1905. Of this sum, two-thirds is due to tartaric acid, of which commodity we take nearly two-thirds of Germany's total export. Germany is, of course, a wine-producing country, and we might expect to find a well-developed industry for the working up of the lees for tartaric acid. It would appear, in fact, that the capacity of the works is well in excess of the home supply of raw material, and that constantly increasing supplies of "weinstein" are being imported from France, Italy, and Spain. Our own returns now include tartaric acid and cream of tartar under separate headings. Great expansion is shown in nearly all the other articles included in this class (A), and it appears to me that in many cases we are importing finished chemicals, the demand for which ought to be satisfied by home manufacture. We have, however, no figures to show the full extent of our requirements in these articles; still less do we know the extent to which they are manufactured in this country, and thus cannot say whether we are allowing Germany to supply a small or a large percentage of our wants.

Turning now to Germany's imports from us (Class A), we find, at first glance, an apparently satisfactory state of affairs, for, excluding unenumerated, we note a rise from, roughly, £460,000 to £600,000. Dissection of the figures shows, however, that this rise is accounted for by the two items, ammonium salts and iodine. As regards ammonium salts, our exports to Germany in 1905 were much above the average value for the preceding 10 years, whilst, in the case of iodine, the chances are that most of it was merely passing through this country in transit from Chili. Excluding these, our trade in other chemicals shows a slight loss, such loss being most noticeable in the cases of barium and strontium salts (£4500), borax (£29,200), phosphorus (£11,300), and white arsenic (£4400)—in all £49,400. There are satisfactory gains in copper sulphate and in chromates; other gains are trifling compared with the gains in exports by Germany shown under the same headings.

Passing now to group B, that is, to materials usually associated with pharmacy, we find—again excluding unenumerated—that, whilst our exports to Germany have only increased by £17,000, their exports to us have more than doubled, and show a gain of over £60,000. The only satisfactory item in this list falls under the heading of "other alkaloids," and here I am glad to say we appear to more than hold our own. We have suffered big drops in our exports of essential oils and quinine, and in both these lines Germany shows marked gain.

Turning to the unenumerated articles under Classes A and B (not given separately in 1895), it will be seen that the German exports to this country form a very considerable item (about £350,000), and many times exceed the imports from us. Under this heading are included many chemicals, some of which represent a large annual value. As to their nature, the "Chemical Trade Journal" affords considerable light. Amongst the more important items may be mentioned acetone, formaldehyde, pyrogallic acid, and thorium nitrate. The latter industry alone must have represented a considerable profit to Germany (our imports for the last three months of 1905 amounted to over £8000), so long as the German Syndicate had control of the ore supply. This will be evident when I state that, as soon as competition was threatened, the price of thorium nitrate was dropped from 53 to 27 marks per kilo.

Classes C (resin oils, varnishes, &c.) and D (explosives) show loss to England, and gain to Germany; they may be passed over without further comment.

Group E, dealing with coal tar derivatives, such as benzol, anthracene, naphthalene, &c., requires notice, emphasising as it does the complaints recently made by Sir George Livesay as to the unsatisfactory conditions of the English tar market. Our loss here is considerable, and is largely owing to the fact that Germany is now able to supply from its own gas works and coke ovens much of the raw material necessary in the aniline colour industry. It may further be noted that Germany is drawing continually increasing quantities of its imports in these products from Austria-Hungary. This competition has not only hit us as regards quantity, but it has also had a most disastrous effect on prices. Thus, the average price for light oils imported into Germany is now only £10 per ton, as against £22 10s. in 1895, and £30—£31 in the two succeeding years. It is worthy of special note that Germany has now developed a considerable export trade in these oils, and that whereas ten years ago and earlier their export price was well below the import price, it is now some 25 per cent. higher. The German imports of anthracene have also fallen to one-fifth to one-quarter of the 1895–9 figures; in the case of naphthalene, however, a large increase is to be noted. This is probably due to the development of the artificial indigo industry, but not entirely so. The exports of naphthalene now reach nearly 3000 tons, and for years past the export price has been almost double that of the import. In both instances the better prices obtained for the export

article are probably due to a greater purity of product, and our tar distillers might find it worth their while to look further into this question.

We now come to Class F, which deals with the aniline and coal tar synthetic dyestuffs, and with pigments generally. This is the most important branch of the German chemical trade, accounting for approximately 40 per cent. of the total chemical exports from Germany, and for 50 per cent. of the chemical exports to this country.

Alizarin, aniline dyes, and indigo are now exported from Germany to England to the extent of over £1,350,000 per annum, an increase of over 50 per cent. compared with the figure for 1895. Our exports to Germany are now less than £30,000, a drop of over £250,000 from the figure of 10 years ago, when natural indigo still held its own, and was sold through this country. Instead of selling indigo to this value, we now buy the artificial product to the value of £178,500.

The other items in this class are in the main inorganic pigments, such as white lead, zinc white, ultramarine, &c. Here we have in all a slight gain of some £14,000 in our exports as compared with 10 years ago; this, however, drops into insignificance beside the German gain of over £200,000.

The picture is sufficiently depressing. As previously stated, it does not represent the course of our chemical trade generally, but, whilst this is so, the trade between ourselves and Germany is fairly typical, certainly as regards exports, of what Germany is doing.

German chemical trade.—Diagram II. indicates the course of German trade over a period of 20 years, and shows at a glance the dimensions and nature of the traffic in raw materials and finished products. The total German imports of chemicals to-day amount to £21,500,000, of which sum a trifle over two-thirds is for raw material. The exports have now a value of over £27,000,000, nearly 90 per cent. of which represents manufactured products. The diagram shows that the import trade has doubled in the period considered, and that the exports have even increased more rapidly still. Whilst the increase in the value of imports is, however, almost entirely for raw material, the increase in exports is, in the main, confined to finished products. The importance of the various sub-groups, and the nature of the changes in these, is shown in Table 2. Of the imports of raw material, more than half the value falls in Class A, and, of this group, nitre is responsible for two-thirds of the total. The other more important items are pyrites and manganese ore, and the figures for these for the two countries are instructive. They are as follows:—

	Pyrites.			
	England.		Germany.	
	Tons.	£	Tons.	£
1895	582,463	987,165	288,000*	291,000*
1905	698,746	1,152,759	540,000	1,056,350

* Included alum ore.

	Manganese ore.			
	England.		Germany.	
	Tons.	£	Tons.	£
1895	131,519	296,948	22,200	56,450
1905	238,700	490,612	258,000	552,350

The pyrites figures alone, as affording an index of the manufacture of sulphuric acid, are sufficient to show the rate of progress and development in the two countries. Sulphuric acid plays a considerable part in many important processes, and Hasenclever's figures for the output and use of the acid in Germany in 1904 will be of interest. The acid made is given as 1,300,000 tons of 60° acid, made up as to 1,100,000 tons from pyrites, and 200,000 tons from blend and gas residuals. Its destination is stated to be: 5—600,000 tons for superphosphate, 150,000 tons for ammonium sulphate, and 250,000 tons (=19 per cent.) by contact process, for dyes and explosives, and the remaining 3—400,000 tons for sodium sulphate, aluminium sulphate, &c. The ammonium sulphate figure gives some idea of the present extent of the gas and coke oven industries in Germany, whilst the 250,000 tons for dyes and explosives illustrates the important connection between these finer chemicals and the heavy chemical trade.

Of imported manufactured materials, we find that Class A accounts for one-third of the total value, and that, in this particular group, ammonium sulphate and iodine are responsible for slightly more than one-half. (Three-fifths to two-thirds of the ammonium sulphate is supplied by England.)

Coming now to the export trade in manufactured products, we find that, at the present time, the value of substances falling in Classes A and F far outdistances the value of the goods falling outside these groups. Group A, amounting to nearly £7,000,000, accounts for approximately 30 per cent. of the total export, and, of this sum, the various potassium compounds are responsible for nearly £2,500,000. Class F, comprising the various coal tar dyes, alizarin and indigo, together with other pigments, organic and inorganic, amounts to 40 per cent. of the exports in finished goods, totalling very nearly £10,000,000, of which over £5,000,000 is for aniline dyes, and over £2,000,000 for alizarin* and indigo. This group, and the associated group E, have undergone the most marked changes in the course of trade during the 20 years considered. Whilst the other groups show more or less steady increases in both exports and imports, these two groups show marked rise in exports accompanied by fall in imports. Prior to 1897, the imports of tar oils and tar products considerably exceeded the exports, whilst to-day the value of the exports is nearly treble that of the imports.

These figures indicate a most healthy condition of the German chemical industry; it is interesting to see whether this view is borne out by other available information.

In the first place, I will give some statistics relating to the number of workpeople employed in the whole chemical (and associated) industries, together with the average wages paid, and the number of processes in operation. These figures are published from year to year by the "Association for the Protection of Chemical Interests," in connection with the system of accident insurance followed in Germany, and undertaken by the above-mentioned association. I would again refer to Mr. Tyrer's address for further details regarding the aims and work of this Society.

Year.	No. of processes.	No. of workpeople.	Average wage. Marks per annum.
1885	4,162†	70,991	(760)
1890	5,043	87,498	821·25
1895	5,947	114,581	894·00
1900	7,169	153,001	1012·00
1905	8,278	185,820	1030·00

† 1886 year.

This table shows remarkable progress, the number of men employed having almost trebled in the last 20 years. It further teaches that the condition of the workpeople has vastly improved, the rate of wages having risen 25 per cent., and that the annual wages bill now amounts to nearly £10,000,000 sterling.

Other information indicates that there is considerable difficulty in finding sufficient labour to meet the requirements of the industry; in fact, during the second quarter of the present year, lack of workers in the sulphuric acid industry is recorded, notwithstanding advances in wages of from 8—15 per cent. In the aniline dye industry, it has also been found necessary to make very liberal concessions to the workpeople to maintain the manufacture in full swing.

The part played by the various sub-divisions of the

* England and British India take nearly one-half of the alizarin exported from Germany.

industry in furnishing employment is shown in Table 3, which gives the details for the years 1892 and 1902 respectively. With the exception of gunpowder all the divisions show, in general, a very marked increase in employment, the greatest activity being found in the manufacture of aniline dyes, other coal tar derivatives, essential oils, varnishes, rubber, and mineral waters. This is in accord with the import and export statistics already given.

Further confirmation of the growth of the industry is to be found in the increase in invested capital, and in the sum paid annually as dividend. The figures, so far as they relate to limited liability companies, are as follows :—

Year.	No. of companies.	Paid up capital.	Dividend.	Average rate per cent.
		£	£	
1886	82	8,127,042	582,995	7·17
1890	82	9,903,655	1,260,460	12·50
1895	95	12,396,045	1,575,427	12·7
1900	121	17,424,650	2,147,707	12·3
1904	143	22,350,850	3,109,785	13·8

The growth of invested capital is probably not so great as the figures would indicate, owing to part of the increase arising from the conversion of private concerns into limited companies. Nevertheless, the table is of interest, and shows the large annual profits made. These profits vary much for the different industries, and even for different works manufacturing similar products, and it must not be assumed that all works give satisfactory returns. As a matter of fact, in 1904, 26 of the works represented in the table paid no dividend at all, and only 52 paid over 10 per cent. Whilst the heavy chemical trade and the manufacture of fine and pharmaceutical chemicals yield handsome returns, the greatest results have been achieved in the aniline dye industry. There are 31 aniline colour works in Germany, but the bulk of the trade is in the hands of five firms, forming two large combinations. The combined nominal capital of these five firms is nearly £5,000,000, and the net annual profits £2,000,000, 60 per cent. of which is paid in dividends, the remainder going to depreciation and reserve. The average dividend of the aniline dyeworks has exceeded 20 per cent. for years past, and the dividend paid by individual firms has in some cases exceeded 30 per cent. The firm of Bayer alone employs 5200 workpeople, whilst the Badische Anilin und Soda Fabrik employs 7251. The average working day is nine hours in the case of the first-mentioned firm, and 10 hours in that of the second, which latter, in 1905, paid an average wage of 4·01 marks per day, as against 3·38 marks in 1895. The Badische firm began business in 1865, and started with only 40 men. The progress has indeed been great.

England's chemical trade.—And now, gentlemen, what can we show? We have successful firms in this country, some remarkably so, and able to present a rate of growth comparable with that of the more successful in Germany and other countries. Still our progress as a whole falls far short of that of Germany, and is not what it ought to be. I must further add that we are working to a large extent in the dark. Where can we find details similar to those given above as to employment, number of processes in operation, and the relative importance of the various branches of our industry? At present it cannot be done, but I am glad to say that there are hopes of improvement in this respect shortly. I refer to the Industrial Census which the President of the Board of Trade proposes for 1908. The announcement that such a census was to be taken has aroused opposition in certain quarters. Personally I feel that the information such a census affords should, if properly used, be of great help to all manufacturers in this country. Very full information of this kind has been available in Germany and the United States for some years past, and in these countries, at all events, the publication has not hindered progress. Whilst welcoming the proposed census, I might at the same time express a hope that the information will be collected and tabulated in such fashion as to render comparison with the figures of other nations easy; the inquiry, at present being conducted by representatives of our Board of Trade in Germany, would rather indicate that such will be the case. Our present census figures certainly leave much to be desired, in so far as they relate to chemical industry.

Coming to such figures as we have, that is, to the trade returns, I have already pointed out how far they are wanting in exactness. Improvement is, however, taking place, and I am glad to see that, in the last issue (fifty-third) of the "Statistical Abstract or the United Kingdom," an attempt has been made to classify our imports and exports into raw material and manufactured products, and to group the individual items under definite headings, whereas, in previous issues, the articles were merely listed in alphabetical order. According to the classification at present adopted by the Board of Trade, the total values of English imports and exports of chemicals, drugs, dyes, and colours (including tanning materials), for the years 1895 and 1905, were as follows :—

	1895.	1905.
Imports	£8,714,360	£9,624,638
Exports—		
English and Irish prod.	11,463,304	14,536,857
Foreign and Colonial	2,309,209	1,473,578
	£13,772,513	£16,010,435

Examination of the lists, however, shows that many articles which, I think most people will agree, ought to be classed amongst chemicals, appear under other headings. Thus salt, which is prepared in an industry long regarded as chemical, and which finds a considerable outlet in alkali manufacture, is classed amongst "other food and drink." Aerated waters (artificial) also fall in the same group. These are grouped with chemical substances in Germany, and certainly chemicals play an important part in the manufacture of artificial mineral waters. Isinglass and yeast are further to be found under the same sub-heading, whilst essential oils are grouped with the various saponifiable oils under "oil seeds, nuts, oils, fats, and gums."

Classification is always a matter of difficulty, and no system—without useless elaboration—will be found perfect. Much depends on the point of view as to whether the origin or the presumed destination or use of a product is to determine its place in the system. In the English classification, undue importance appears to be given to the destination of the individual articles—this is, however, a matter for argument. Of more importance is the grouping into raw material and manufactured products, and, considering the weight attached to this point in recent controversies, one would have expected at least an approximately correct classification here. Instead of this, we find essential oils and turpentine under "Raw materials and articles mainly unmanufactured," whilst boracite, Peru bark, the various tanning barks, myrobalans, and galls appear as "Articles wholly or mainly manufactured." These last-mentioned articles are entirely natural in their occurrence and origin, and have not undergone any manufacturing operation; the sole labour expended has been that of collecting. They represent a considerable percentage of our imports and also of our exports of foreign and Colonial produce, and, for this reason, correct classification is a matter of some importance. You will thus see that our figures are not directly comparable with those of Germany. Much addition is necessary, and also certain elimination, soap and artificial manures not appearing with the other chemicals in the German list already given.

I have made an attempt to compare our trade with that of Germany, adopting the German classification as a basis and taking the same years, 1895 and 1905, as before. The result is embodied in Table 4, but I do not wish too great importance to be attached to this table, because of the impossibility of separating raw products from manufactured materials in the cases where "unenumerated," generally of large value, appears in our list. I have ranked such "unenumerated goods" as manufactured products, both when appearing as chemicals and as drugs, though in the latter case I feel certain that much is in the nature of raw material.

article are probably due to a greater purity of product, and our tar distillers might find it worth their while to look further into this question.

We now come to Class F, which deals with the aniline and coal tar synthetic dyestuffs, and with pigments generally. This is the most important branch of the German chemical trade, accounting for approximately 40 per cent. of the total chemical exports from Germany, and for 50 per cent. of the chemical exports to this country.

Alizarin, aniline dyes, and indigo are now exported from Germany to England to the extent of over £1,350,000 per annum, an increase of over 50 per cent. compared with the figure for 1895. Our exports to Germany are now less than £30,000, a drop of over £250,000 from the figure of 10 years ago, when natural indigo still held its own, and was sold through this country. Instead of selling indigo to this value, we now buy the artificial product to the value of £178,500.

The other items in this class are in the main inorganic pigments, such as white lead, zinc white, ultramarine, &c. Here we have in all a slight gain of some £14,000 in our exports as compared with 10 years ago; this, however, drops into insignificance beside the German gain of over £200,000.

The picture is sufficiently depressing. As previously stated, it does not represent the course of our chemical trade generally, but, whilst this is so, the trade between ourselves and Germany is fairly typical, certainly as regards exports, of what Germany is doing.

German chemical trade.—Diagram II. indicates the course of German trade over a period of 20 years, and shows at a glance the dimensions and nature of the traffic in raw materials and finished products. The total German imports of chemicals to-day amount to £21,500,000, of which sum a trifle over two-thirds is for raw material. The exports have now a value of over £27,000,000, nearly 90 per cent. of which represents manufactured products. The diagram shows that the import trade has doubled in the period considered, and that the exports have even increased more rapidly still. Whilst the increase in the value of imports is, however, almost entirely for raw material, the increase in exports is, in the main, confined to finished products. The importance of the various sub-groups, and the nature of the changes in these, is shown in Table 2. Of the imports of raw material, more than half the value falls in Class A, and, of this group, nitre is responsible for two-thirds of the total. The other more important items are pyrites and manganese ore, and the figures for these for the two countries are instructive. They are as follows:—

	Pyrites.			
	England.		Germany.	
	Tons.	£	Tons.	£
1895	582,463	987,165	288,000*	291,000*
1905	698,746	1,152,759	540,000	1,056,350

* Included alum ore.

	Manganese ore.			
	England.		Germany.	
	Tons.	£	Tons.	£
1895	131,519	296,948	22,200	56,450
1905	238,700	490,612	258,000	552,350

The pyrites figures alone, as affording an index of the manufacture of sulphuric acid, are sufficient to show the rate of progress and development in the two countries. Sulphuric acid plays a considerable part in many important processes, and Hasenclever's figures for the output and use of the acid in Germany in 1904 will be of interest. The acid made is given as 1,300,000 tons of 60° acid, made up as to 1,100,000 tons from pyrites, and 200,000 tons from blend and gas residuals. Its destination is stated to be: 5—600,000 tons for superphosphate, 150,000 tons for ammonium sulphate, and 250,000 tons (=19 per cent.) by contact process, for dyes and explosives, and the remaining 3—400,000 tons for sodium sulphate, aluminium sulphate, &c. The ammonium sulphate figure gives some idea of the present extent of the gas and coke oven industries in Germany, whilst the 250,000 tons for dyes and explosives illustrates the important connection between these finer chemicals and the heavy chemical trade.

Of imported manufactured materials, we find that Class A accounts for one-third of the total value, and that, in this particular group, ammonium sulphate and iodine are responsible for slightly more than one-half. (Three-fifths to two-thirds of the ammonium sulphate is supplied by England.)

Coming now to the export trade in manufactured products, we find that, at the present time, the value of substances falling in Classes A and F far outdistances the value of the goods falling outside these groups. Group A, amounting to nearly £7,000,000, accounts for approximately 30 per cent. of the total export, and, of this sum, the various potassium compounds are responsible for nearly £2,500,000. Class F, comprising the various coal tar dyes, alizarin and indigo, together with other pigments, organic and inorganic, amounts to 40 per cent. of the exports in finished goods, totalling very nearly £10,000,000, of which over £5,000,000 is for aniline dyes, and over £2,000,000 for alizarin* and indigo. This group, and the associated group E, have undergone the most marked changes in the course of trade during the 20 years considered. Whilst the other groups show more or less steady increases in both exports and imports, these two groups show marked rise in exports accompanied by fall in imports. Prior to 1897, the imports of tar oils and tar products considerably exceeded the exports, whilst to-day the value of the exports is nearly treble that of the imports.

These figures indicate a most healthy condition of the German chemical industry; it is interesting to see whether this view is borne out by other available information.

In the first place, I will give some statistics relating to the number of workpeople employed in the whole chemical (and associated) industries, together with the average wages paid, and the number of processes in operation. These figures are published from year to year by the "Association for the Protection of Chemical Interests," in connection with the system of accident insurance followed in Germany, and undertaken by the above-mentioned association. I would again refer to Mr. Tyrer's address for further details regarding the aims and work of this Society.

Year.	No. of processes.	No. of workpeople.	Average wage. Marks per annum.
1885	4,162†	70,991	(760)
1890	5,043	87,498	821·25
1895	5,947	114,581	894·00
1900	7,169	153,001	1012·00
1905	8,278	185,820	1030·00

† 1886 year.

This table shows remarkable progress, the number of men employed having almost trebled in the last 20 years. It further teaches that the condition of the workpeople has vastly improved, the rate of wages having risen 25 per cent., and that the annual wages bill now amounts to nearly £10,000,000 sterling.

Other information indicates that there is considerable difficulty in finding sufficient labour to meet the requirements of the industry; in fact, during the second quarter of the present year, lack of workers in the sulphuric acid industry is recorded, notwithstanding advances in wages of from 8—15 per cent. The part played by the various sub-divisions of the

* England and British India take nearly one-half of the alizarin exported from Germany.

and all must be removed before a full and satisfactory advance can be made. In addition, steps must be taken to avoid mistakes in the future. We must not be content to wait, as we have too often done in the past, until our grievances have become acute, and then expect to effect a cure by forming a deputation to the Government of the day. No, we must act before matters have reached this stage; in other words, we require a close and continuous touch and co-operation between the Government and the representatives of the country's industries. With such co-operation, difficulties would be officially recognised as they arose, and preparations made to prevent them assuming giant and almost insurmountable proportions. There are already signs of improvement in this direction, for we now have an advisory committee of business men to the Board of Trade, and, in the near future, we are to have a Minister of Commerce. Our disabilities must, however, be made known, and united effort on our part ought to accomplish much. Our Society is, as regards chemical industry, a thoroughly representative body, and holds to-day a strong and influential position. It has shown initiative and skill in dealing with matters of public importance, and, to judge from Dr. Divers' presidential address of last July, it is prepared to continue its activities in such direction. Dr. Divers expressed the hope that "the Society may soon have a Royal Charter to work under, and so secure for its recommendation even greater consideration in legislation and other public matters than they have already received." (Presidential address, 1906.) The fulfilment of this hope rests largely with our members, and I would urge them to carefully consider the facts disclosed in this paper and to discuss what can be done to remedy the present state of affairs.

We certainly ought to have the same full information as to our industrial progress and position as is available in Germany and in the United States, for only with such information can we know where we are strong, and where weak, and discover the road in which improvement lies.

I had originally intended to say something about certain of the later discoveries and inventions in manufacturing chemistry, to refer to the number of uses, many of them important, now being found for elements and compounds which were until recently regarded as rare, and, to the manufacturer, comparatively valueless. I had also wished to discuss the industrial development now taking place in countries which, up to a year or so ago, were dependent on ourselves and others for the bulk of their supply of chemical products. All these points demand attention in considering the prospects of our present industries, and in helping us to shape our future course.

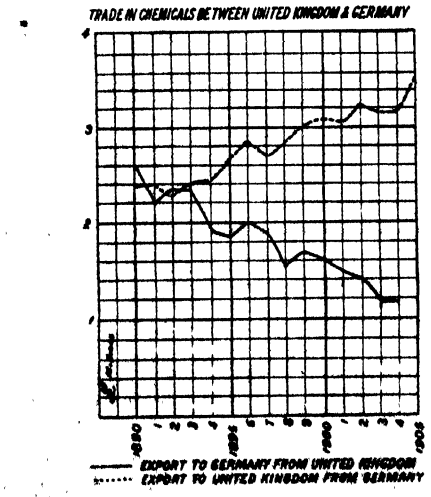

FIG. 1.

The address has, however, already reached a sufficient length, and to now go into further detail would only lead to weariness. If what I have written should lead to a better understanding of the present position of our country's trade in chemical products, and further emphasise our large and inexcusable dependence on Germany for what are looked upon as necessities in to-day's progressive age, this address will not have been in vain.

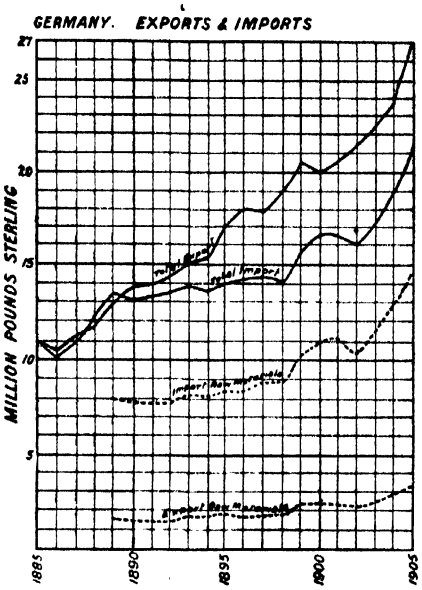

FIG. 2.

TABLE 5.

England and Germany—Increases in Imports and Exports, 1895—1905.

		England	Germany.
Imports.		£	£
Raw materials	1905	8,802,072	14,527,950
	1895	8,091,003	8,443,850
Increase		711,069	6,084,100
Manufactures	1905	9,106,496	7,014,550
	1895	7,158,044	5,546,850
Increase		1,948,452	1,467,700
Of which Groups A. and B.	1905	4,440,789	3,842,300
	1895	3,143,861	2,077,350
Increase		1,296,928	1,764,950
Exports.			
Raw material	1905	2,006,585	3,325,550
	1895	1,515,162	1,863,200
Increase		491,423	1,462,350
Manufactures	1905	15,455,402	23,701,500
	1895	13,593,471	15,094,150
Increase		1,861,931	8,697,350
Of which Groups A. and B.	1905	11,089,544	9,432,950
	1895	8,621,243	6,705,850
Increase		2,468,301	2,727,100

Note.—In the English figures exported salt has been ranked as a manufactured article.

DISCUSSION.

Prof. WILHELM OSTWALD said that the causes of the present situation and its cure were so well known that it was not revealing a secret to repeat them once more. They might sum up the facts by saying that Germany had managed to put more brains into her goods, or, if they preferred a more scientific expression, to combine more mental energy with the rough energies of primary material. As mental energy was the most valuable kind of energy, the value of the goods was enhanced in proportion to the percentage of the mental energy embodied in them. Now there was no doubt that the English store of mental energy was at least as great as the German one; the only difference was, therefore, that here the channels leading that energy into industry were not so broad or deep or numerous as in Germany. There seemed to exist in parts of Great Britain not only a disregard for, but even a mistrust in science or theory. In Germany everybody trusted science, even the Government. They were quite accustomed to consult a scientific expert before going into a new business. Of course there were cases in which they failed to act in this way, but then they generally fell into scrapes. Sometimes even theory led into scrapes; but it proved to be bad or incomplete theory. But the sum total of experience had convinced them of the value of theory, and their trust in it was rather too large than too small.

The common argument of the practical man against theory was that science had no practical value. This could be disproved at once by the fact that flourishing German chemical factories spent no small sum of money on scientific laboratories. Perhaps he might tell them his own experience as a theoretical inventor. Several years ago, when the newspapers had managed once more to construct the appearance of strained relations between Germany and England, one of his colleagues, a very clever, but a little too anxious man, pointed out that, in case of war, the export of saltpetre from Chili to Germany could be interrupted by England, and then they would have to stop fighting altogether. This position being unbearable to a patriotic physico-chemist, some remedy had to be discovered. Before a fortnight was gone, his assistant, Dr. Brauer, and himself had found out, experimentally, how to transform ammonia into strong nitric acid, with an output of 100 per cent. of the theoretical value. Thus, he thought, the main thing was done; but when the process was tried on a larger scale it was at once clear that *one* invention was *no* invention, every central invention requiring quite a number of secondary ones to put practical life into it. The misunderstanding of this general fact had surely led very often to a misunderstanding of the value of science.

In a year or so, however, these difficulties were got over, and an output of 85 per cent. to 92 per cent. was reached in a plant built on the scale of a small factory. Now they were building works in Westphalia to convert about 50 tons of ammonia a month into nitric acid. During this whole development (and this was the reason why he related this bit of personal experience) he never found any difficulty in getting money for these experiments on a large scale. The leading men with them were quite accustomed to spend money for costly experiments, the issue of which was uncertain, though hopeful, when the thing was based only upon laboratory experiments, *i.e.*, upon scientific evidence. To risk a considerable amount of money on such a small evidence seemed the most convincing proof of the real trust in science prevailing in Germany.

A foreigner was, of course, the last person to teach them how to develop a similar state of mind in their own land. In discussing these matters with his English friends he had been told over and over again how difficult they found it to overcome existing resistances. But he was sure these difficulties were considerable only in the beginning of the work. Once bring the carriage over the top of the hill and it would go by itself.

The CHAIRMAN said that Prof. Ostwald had emphasised, first, the belief of the German Government and people in the value of science, and secondly, the close touch between scientific men and the German Government, coupled with the readiness of the Government to deal with a scientific problem in the proper way, instead of leaving such problems entirely to politicians as they did in England. They certainly wanted closer touch between the leaders of scientific thought and the Government than they had had up to the present. They were all glad to hear that Prof. Ostwald had been so successful in his nitric acid manufacture.

The PRESIDENT of the Society expressed their indebtedness to Prof. Ostwald for the very interesting remarks he had made. He then proposed a very hearty vote of thanks to the Chairman for his address, which he thought well worthy of discussion at another time.

Dr. J. CAMPBELL BROWN, in seconding the vote of thanks, said that in order to bring industries in this country into their proper position, they must make their power as a united body felt by the Government. Whatever manufacturers felt they required, that they had to impress upon the minds of their rulers, whoever they might be; and that was the great lesson that Germany taught them.

Prof. DONNAN understood the Chairman to say that 85 per cent. of the bleach exported from Germany was made from electrically-produced chlorine. Where was

the chlorine got for the production of bleach in England as compared with Germany? If Germany were using 65 per cent. of electrolytic chlorine, why was not England? Had the Germans not so much hydrochloric acid available as the English?

The CHAIRMAN said that he would be very pleased to follow the President's suggestion and to have a discussion upon the points in this address at some future date, if the members wished it.

With regard to Prof. Donnan's question, he had no personal knowledge of what was done in Germany. He merely quoted the statement made by Hasenclever, that 65 per cent. of the bleach produced in Germany was produced electrolytically, and chiefly from potassium chloride. There were three points to be considered in looking at the commercial aspect: In the first place, electrolysis gave per unit of current a much greater output of caustic potash than it did of caustic soda. Secondly, caustic soda was very easily produced by the Leblanc process, caustic potash only with great difficulty; and thirdly, caustic potash had a relatively high selling price, and caustic soda a low one. The difficulty of making caustic potash by the old process, and the higher price of caustic potash, were the main points which made the electrolytic potash industry so profitable in Germany, and explained why electrolysis should be so much more profitable in the case of potassium chloride than in that of sodium chloride.

In conclusion, he wished to express his indebtedness to Mr. Pritchard and also to Mr. Anderson for the care they had taken in the production of the diagrams and the tables of figures.

London Section.

Meeting held at Burlington House, on Monday, June 11th, 1906.

MR. A. GORDON SALAMON IN THE CHAIR.

RECENT PROGRESS IN THE CEMENT INDUSTRY.

BY BERTRAM BLOUNT.

During the last 20 years the cement industry has undergone a process of evolution which has been of great importance and significance to itself, and, as a consequence, to those arts which utilise its product. It is not much more than 20 years ago when the manufacture of cement was carried on as an empirical trade; at the present time it is recognised as one of the largest chemical industries, and, as all chemical industries must be, is directed by the chemist and the engineer. Its increase in size is only less striking than its growth in precision; both are probably small compared with the development which may reasonably be expected. The growth may be judged by the figures for production and export given in Appendix A. Although not as complete as could be wished, they will serve to illustrate the great expansion of trade which has taken place in cement.

In the earlier days of the cement industry, manufacture was to a large extent confined to places where the natural conditions were peculiarly favourable, and even at the date chosen as a starting point (1886) many of the sources of supply which are now in active operation were either unutilised or were developed to so small an extent that their influence on the older centres of the trade was trifling. But because cement is a heavy and cheap commodity, and because with proper knowledge and skill it can be made from a great variety of raw materials very widely distributed in the earth's crust, this condition of things could not persist. In fact, the preparation of cement is naturally a local manufacture, and the conveyance of the material for long distances from a few large centres is economically anomalous. The removal of this anomaly, though of great ultimate advantage to the cement industry and to the many trades in which cement is used, has been attended by those temporary hardships which inevitably occur when the conditions of commercial success in any given industry are substantially modified. The great producing centres, especially those in this country and in Germany, which had been developed rapidly on the strength not merely of their command of their home market, but also on their reliance on a great export trade, found themselves gradually opposed in those countries to which they were accustomed to export cement by a growing local manufacture, and in consequence had to be content with a non-progressive or diminishing export, or were obliged to lower their prices in foreign markets to a point that was barely remunerative. This natural shifting of the centre of gravity of the cement industry, if it had taken place gradually, would have inflicted little injury to those manufactories whose position was economically sound; but it happened, during the time I am dealing with, that the largest single customer for exported cement —the United States—took up and developed its home manufacture on so huge a scale and with such rapidity that the European works found themselves deprived of an outlet for a large part of their product with inconvenient celerity, losing a valuable consumer before they had time to find or create other directions in which their cement might be profitably disposed of.

As a result of this alteration in trade conditions it became of urgent necessity to effect economies in manufacture, and it is the steps which have been taken for this purpose which appear particularly worth discussion, as they have brought about such alterations in the mode of manufacture as have changed the whole technique of the industry. Perhaps the simplest way of illustrating the change is to compare a works typical of what was general practice in 1886 with one which represents the practice of to-day.

There are, of course, various modifications of manufacture according to the nature of the raw materials, and twenty years ago these differences equally existed; there were works using wet raw materials and washing them to a slurry; works using dry raw materials, grinding them, and moulding the product into bricks; works using discontinuous kilns of the chamber type, and others continuous kilns of the shaft or of the ring type; works having millstones for grinding the clinker, and others employing pulverisers with metallic grinding surfaces of various design. Similarly to-day there are works in which slurry is prepared and others where the material is dried, and there are still different opinions about the best form of grinding apparatus. But in all this diversity in practice then, and similarity between practice then and now, two facts differentiate the two periods sharply. In 1886 the fixed kiln and the millstone were in general use and were generally approved; in 1906 they are obsolete and have been replaced the one by the rotatory kiln and the other by one of two types of grinding apparatus, which will be particularised later. On account of the shifting of the centre of the industry from the districts using wet raw material to those employing dry (due largely to the enormous growth of the manufacture in the United States), and on account of the fact that already there is a tendency even in the wet districts to consider whether the materials should not be dried before they are mixed, it is convenient to take as our illustration a works such as once was common on the Thames and Medway using wet raw materials, to exemplify 1886 practice, and a works such as is put up in any region where dry raw materials are available, to represent the practice of to-day.

In a typical wet process works in 1886, chalk and clay were brought to the wash-mill in their natural moist state in barrows, as quarried or dug, and there mixed in the proportion of about three to one, using a barrow-load as a unit. In some of the better equipped works the loads were weighed, but in most this was regarded as a needless refinement. No determination of the water present in the raw materials was attempted, and the very considerable variations which occur were rectified, as far as the judgment of the man in charge of the wash-mill allowed, by the occasional addition or withdrawal of

a portion of the clay. In the wash-mill the materials were made into a slurry containing 40 to 45 per cent. of water, and the flints eliminated. The slurry was sometimes passed between grinding rings, and frequently was sent from the wash-mill to wet millstones, where the coarser particles of chalk were ground. But at that date it was not universally recognised that the grinding of the raw materials must be fine, and in consequence a sample of ordinary slurry often gave a residue of several per cent. on a 40 by 40 mesh sieve. This residue consisted largely of chalk, and undoubtedly was a source of unsoundness in the finished cement. After the wash-mill (or the wet stones as might be the case) the slurry went, without further preparation as a rule, to the drying floors of chamber kilns. The use of dosage tanks was not general, in this country at least, and no opportunity was given for correcting the composition of the wash, although means of correction were certainly desirable both because of the primitive method of measuring the proportions of the raw materials, and because even when wet stones were used the chalk ground by them had little chance of being uniformly distributed throughout the mass of the slurry, so that the full advantage of the finer grinding was not obtained. The usual method of ascertaining whether a proper mixture had been obtained was to burn a small quantity in a trial kiln and examine the resulting clinker. Evidently it was then too late to correct the mixture. The use of the calcimeter was not at that date general.

The slurry, dried on the drying floors of the chamber kilns, was removed by hand and carried to the kiln. The whole of the loading of the kiln was by hand, slurry and coke being brought in barrows or skips and stacked in alternate layers until the kiln was full. The kiln was then fired, and if of average size burnt off in four or five days. Unloading the kiln was done by hand, and the clinker carried in barrows to the grinding plant. During unloading the underburnt material from the top of the charge was kept separate, as far as possible, from the bulk of well-burnt clinker, and some picking out of inferior material took place; but it will be easily understood that there were great difficulties in the way of its complete removal, even with careful and vigilant management. It was quite common to omit picking and send substantially the whole product of the kiln to the crushers.

At this period millstones were in almost universal use for grinding the clinker. They were relatively cheap to erect, but very costly to maintain, and required a number of skilled artisans to dress them. The output per pair of stones was small and the horse power required was large. In fact, as a comminuting apparatus, they have nothing to recommend them except the difficulty of reducing the percentage of coarse, gritty particles; in consequence of this difficulty, the remainder of the cement must be ground for a long time, and is thus made very fine, or "floury." When sieves are used in conjunction with the stones, this advantage tends to disappear.

The cement made in the manner described was regarded, and rightly, as an unfinished material. It needed to be matured by aëration and storage, or in works' parlance, it had to be "cooled." The notion of "cooling" no doubt arose from the accident that the cement is physically hot when it comes from the stones, and the notion was conveniently extended to the slaking of those unsaturated lime compounds which are apt to exist in a product imperfectly mixed and irregularly burnt. There is no doubt that, under the conditions then existing, this storage and maturing was of the greatest value as a safeguard to the user, and it is only now—20 years later—when, with better means of manufacture, the precaution is almost superfluous. Even now cases arise in which cement is not sound when it leaves the grinding machinery, but such instances are becoming rarer, and may reasonably be expected to disappear with the growing improvement in manufacture. The manufacturing cost of cement 20 years ago, at a typical works of fair size, say, making 500 tons a week, and run with a sufficient application of the skill and knowledge then available, may be taken at an average figure of 18s. a ton, assuming a normal price for gas coke of 11s. per ton. A large part of this cost (about 5s. 6d.) was incurred for labour, as the heavy work of loading the kiln and carrying the clinker to the grinding plant was all done by hand.

Another large item was for fuel, both for power and for burning. The high cost for power was due to the wasteful methods of raising and using steam which were then general; the necessity for employing large coal of steam quality in the absence of mechanical devices for feeding small cheap coal, the production of low-pressure steam, and the use of uneconomical engines, all tended to make the production of power dearer in those days; but as these causes of waste were equally active in all industries at that date, no special comment need be made as to their effect on the cost of manufacture of cement. It is sufficient to note that as a good deal of power is used in making cement (the amount varying from 1 to 2 h.p. per ton per week), the cost of production has fallen naturally with the lowering of the price of energy which has been achieved within the last quarter of a century.

But under the old manufacturing régime there was another serious cause of expense in the cost of the coke needed for burning the raw materials to clinker. At one time the cement maker was accustomed to make his own coke, but in more recent times his supply was obtained from gas-works. As no form of fuel could be satisfactorily substituted for coke, the cement maker was a good deal in the hands of the gas companies, and at times he experienced inconvenient pressure from high prices. These three items, labour, high cost of power, and high and uncertain cost of coke, made any permanent or substantial reduction in cost of manufacture seem unlikely as long as the methods of 1886 were in use.

A typical works of the present time differs altogether from the works of 20 years ago which I have attempted to sketch. The contrast between the two represents the vast difference in knowledge which separates the two periods. The empirical stage has closed, and the use of scientific methods is accepted and in process of establishment.

It seems not improbable that the use of materials in a wet state will be superseded, and in consequence it is convenient to take a works using dry raw materials as typical of the most advanced practice. Of course, wet raw materials will continue to be used, but they will be dried before their manufacture into cement is begun. It follows that a works using dry raw materials does not merely represent the greater part of modern manufacture, but it also exemplifies what may become universal practice.

In a modern works using dry raw materials, these are dealt with in truck-loads instead of barrows; manual labour is suppressed wherever possible. The materials are weighed approximately, crushed in crushers of the coffee-mill type, and dried in rotatory driers. The drying is as important for ensuring the proper mixture of the raw materials as is the thorough mingling with a sufficient quantity of water in the case when wet raw materials are used. Although in all cases very fine grinding and most intimate mixing are requisite, yet this necessity is more urgent with some raw materials than with others. For example, typical dry raw materials are limestone and shale, and these may vary widely in composition. If the limestone is nearly pure calcium carbonate, evidently it will need more thorough mixing with the shale than if it is siliceous and consequently already contains naturally and intimately mixed with it a large proportion of those acid oxides with which the lime must be caused to unite in order to produce cement. The extreme case is reached when, as sometimes happens, the limestone contains enough silica and alumina to form cement without the admixture of a second material. Even in this instance the limestone must be well ground and mixed, because it is rare indeed that the siliceous constituents are distributed through the mass of the calcium carbonate uniformly. The same necessity, of course, arises when marls containing an appropriate amount of clay are used instead of limestones.

In a typical modern works the grinding of the raw materials is carried out in mills either of the Griffin or Huntington class, or of the ball and tube kind. Both sorts have their merits and their advocates, and both are greatly better in economy of power and in output than

the millstones which they have replaced. The fine dry coal is mechanically transported, generally by some form of screw conveyor, to large bins, from which the kilns are fed. These bins are a characteristic necessity of a modern cement works. The necessity arises from the fact that as the rotatory kiln runs continuously there must be a store of raw material for feeding the kiln large enough to supply the kilns over Sunday and at other times when the grinding plant is not running. The bins are naturally placed above the upper end of the rotatory kilns, and their contents are fed in by a worm or similar device, so that from the time the raw material is tipped into the crusher to the time when it enters the kiln it is not touched by hand. On account of the fact that the raw materials are dried and then accurately weighed, their proportions are kept within very narrow limits. If any correction is necessary it is done at once by the addition of a small quantity of one or other of the two materials before the bins are reached. In a modern works of the kind, variations of the composition of the raw material on the site are constantly watched, and the mixture correspondingly controlled by analysis. In consequence, subsequent correction is rarely necessary.

All the preceding part of the evolution of the manufacture might have been expected to take place on these or parallel lines, even if no successful form of rotatory kiln had been devised, but the rapidity of evolution and the particular line along which it has proceeded are directly dependent on the arrival of the rotatory kiln. The history of the rotatory kiln has been written elsewhere, and I do not propose to repeat it now. It is sufficient to consider the machine as it exists. A few years ago the rotatory kiln was about 60 ft. long and 6 ft. external diameter, and had an output of about 1 ton an hour or 170 tons per week. At the time of writing the size has reached 120 ft. by 8 ft. 6 ins., and the output is not less than 400 tons per week. Thus a single kiln is capable of the output of what would have been considered a moderate sized works in 1886. At the present time the output of one particular factory is some 25,000 tons per week, equivalent to the output of 25 largish works of the old type.

The dry, finely powdered raw materials find their way mechanically down the rotatory kiln and are met by fuel propelled mechanically. The preparation of the fuel is important, and characteristic of modern practice. It may be said that powdered coal is almost universally used, and that it is conveyed into the kiln by a blast of air. The coal must be very finely powdered, and, in consequence, has first to be dried. As powdering is necessary, cheap small coal is used, a great advantage being secured over the older process, where a dearer fuel and one the supply of which was limited and local had to be employed. The small coal is dried in a rotatory drier and is mechanically taken to the grinding plant, which is one of the two types used for the raw materials, viz., mills of the Huntington or Griffin type or those of the ball and tube class. The powdered coal is carried to bins, again being transported mechanically, which hold a sufficient supply for the kilns on Sunday, during the night, and at other times when the coal-drying or grinding plant may be out of operation.

The three products of the rotatory kiln are clinker, coal ash, and burnt gases, and all escape from the kiln without manual aid. The process of unloading the clinker, which is laborious and disagreeable in fixed kilns, disappears. The automatic removal of the burnt gases is the same in both cases. The removal of the ash of the fuel is a debatable merit. There is a substantial quantity of ash reckoned on the weight of the clinker, and this in the rotatory kiln goes almost wholly up the flue; in the older method it was incorporated with the product from the kiln, and increased the output by about 3 per cent. But the advantages of the rotatory kiln are so manifest that until it is replaced by some apparatus based on a different principle it is the only burning plant worth consideration under ordinary conditions of manufacture. These advantages were apparent nearly 20 years ago, but on account of practical difficulties were not fully attainable until some 10 years later. It is peculiarly gratifying to those—and they were few indeed—who were convinced from the first that the rotatory kiln would displace the older forms, to find at the present time that the event has justified their views.

At present only one of the three products of the rotatory kiln is utilised, namely, the clinker, and as this is a description of contemporary practice, it alone need be considered. The clinker emerges at a temperature of about 1200°—1300° C., and has to be cooled. Usually this is done in an inclined revolving cylinder like the rotatory kiln, but smaller and unlined; in the best practice the cooled clinker is allowed to fall into trucks, which are run on rails to the storage bins, or on to a travelling band, or into the boot of an elevator, and by these to the bins, mechanical transport being adopted at this point as in the earlier stages of the process of manufacture. In the process of cooling, generally at the exit from the cooling cylinders, the clinker is usually sprinkled with water. This is done to slake any unsaturated lime compounds which may have resulted from imperfect mixing and burning. In a rotatory cement kiln properly run there should be almost no badly burned clinker, and as picking of such small material is evidently impracticable it is essential that this condition should be approached; hence the sprinkling with water is a precaution rather than a necessity as far as slaking lime compounds which might cause unsoundness is concerned. But the sprinkling has another object: it is done to regulate the setting time of the cement, which may be necessary for the following reason. When an ordinary mixture of raw materials is burnt in a fixed kiln a great part of the sulphur in the fuel remains as sulphate in the clinker; in a rotatory kiln the fuel is burnt almost out of contact with the clinker, and its products, even the ash, pass away. Hence the clinker contains sulphates corresponding only with the sulphur present in the raw material. As sulphates tend to lengthen the setting time, it is natural that clinker from which the sulphate derived from the fuel is excluded should set more quickly than that which contains this sulphate, and, as a matter of experience, clinker from a rotatory kiln is apt to be quick-setting. Artificial maturing by the regulated addition of water goes far to qualify this tendency.

The slightly moistened clinker is kept in the storage bins, and is transferred mechanically to the grinding plant, the absence of manual labour at this point being in striking contrast to the old plan requiring a small army of labourers with barrows to carry the clinker from the kiln to the crushers. On account of the uniformly small size of the clinker, crushers can as a rule be dispensed with, or used at most to crack up any large lumps which may have formed by the agglomeration of the small nut-like pieces of clinker into rough balls. The grinding plant is usually a duplicate of that used for the raw materials, consisting of Griffin or Huntington mills, or more frequently ball and tube mills. During the process of grinding the small quantity of water added to the clinker becomes incorporated with the finely ground cement, and performs its function of slaking any loosely combined lime and in lengthening the setting time. In some works this slaking is effected in the tube mills by blowing in steam, the purpose served being the same as that accomplished by watering the clinker. The cement is carried by screw conveyors or some similar method of transport to storage bins, and in some cases fed from these by gravity into sacks or barrels, untouched by hand throughout. To one familiar with the older type of works, nothing is more striking than the appearance of a modern works, in which full advantage has been taken of mechanical means of transport. Throughout the works there are signs of great activity, and yet an almost complete absence of men. At the crushers for the raw materials there will be a few; about the fine grinding plant one or two hands sauntering about with oilcans; on the platforms in front of the rotatory kiln a few burners, perhaps one to each pair of kilns; and a greaser or two looking after the driving gear of the kilns; in the cement grinding plant no one but the necessary oiler—and someone watching the conveyors, perhaps. The whole process of manufacture has been brought very nearly to that ideal state of industry where the man is put into his proper place of supervisor and is not used as a sentient machine.

Almost the opposite change from ancient to modern procedure in point of the process of manufacture, is the alteration which has occurred in the power plant. It would be out of place to deal with this in detail here, because the change is not characteristic of the cement industry, but is general in industry. Whereas at the earlier date (1886) power was provided by curious old steam engines working at something above atmospheric pressure and consuming almost as many pounds of coal per h.p. hour as their successors consume of steam, nowadays a cement works rightly thinks itself behind the times if it is not equipped with the most modern form of engine. I say "engine" advisedly, because the best form ultimately to be adopted has yet to be settled. Usually the cement maker has been content with compound or triple expansion reciprocating steam engines, but he is passing easily to the use of large gas engines or of Diesel oil engines. Steam turbines may present a little difficulty as their rate of rotation is inconveniently large, but they are by no means to be overlooked. Whatever the outcome, it is certain that in a modern works a modern power plant must be adopted, because the cost of power is a substantial fraction of the whole cost of cement manufacture, and the margin of profit is not so great as to permit of any but the best appliances. The same limitation makes an economical method of distributing the power of importance only second to that of its production, and in consequence electrical methods of distribution are freely used in modern cement works.

As a result of this alteration of procedure, the manufacturing cost of cement has been substantially reduced. As stated above, the cost at the works by the older methods was about 18s. per ton under ordinarily favourable conditions. By the modern method, and under similar conditions, the cost is about 13s. per ton. These figures are taken as representing fairly enough the difference in cost of the two processes. It would be easy to find exceptions to them, and no doubt examples of higher and lower cost by each process might be cited, but such citation does not affect the argument that by the adoption of modern methods a substantial economy in manufacturing cost has been obtained. Incidentally to this change, there has been, as already indicated, a shifting of the centre of gravity of the trade, and at the present time the users of wet raw materials are at some disadvantage.

The expansion of the manufacture during the period under discussion is shown by the figures given in Appendix A, already mentioned. The utilisation of this greatly increased output has been due to the general increase in engineering and structural enterprises of all kinds, and to the fact that all builders—using that term in its broadest sense, from the greatest architect to the humblest building contractor—have been gradually replacing many of their older materials of construction by cement concrete and mortar. It is beginning to be realised that lime mortar is a poor structural material, and wherever possible cement mortar is substituted for it. A great variety of systems of construction in what is known as armoured concrete have been devised and are being daily extended in use; the manufacture of artificial stone is constantly increasing, and requires great quantities of cement. These causes of increased consumption fall ultimately under two heads: (1) The greater use of cement for well-known purposes, and (2) the growing use of cement for new purposes. Both follow pretty closely the enormous increase in constructional work which has occurred during the last 20 years.

Comparison of the ancient and modern methods of manufacture being completed, it may be useful to consider the present position of the industry. The essentially local nature of the trade will be allowed on all sides, and also that wherever there are natural deposits of suitable acid and basic oxides the industry can be established if fuel is even moderately dear. It follows that profitable manufacture in this country is no longer assured by the natural advantages of excellent raw materials and cheap fuel, but depends upon the skill and enterprise of the manufacturer. Every industry goes through periods of inflation and depression, and in the former there is so great a tendency to be content with old and imperfect methods, and in the latter there is [illegible] a damaging trade; and something of the sort has occurred in this particular industry. There has been a period of depression partly due to outside causes, some of which are permanent, and partly to a want of realisation of the fact that industrial methods are changing. Some have argued from this delay in realising his new industrial position that the cement maker in this country is dead, but such a statement is not just. It must be remembered that his old position was one apparently of great security, and that more than usual prescience would have been required to foresee (*a*) that he would lose almost at a stroke his importance in the world's output, and (*b*) that with diminished resources he would have to rebuild his works. To adjust oneself to so altered a position, easy to state but most uncomfortable to occupy, certainly needs a little time, and the time has been spent in a fruitful manner. There are now in operation in the United Kingdom cement works which are on level terms with the best abroad, and the quality of their product is of equal excellence.

A discourse on recent progress in the cement industry would be incomplete if some account were not given of the relative importance at the present time of the chief varieties of hydraulic cement. Portland cement stands first, a long way ahead of any of its congeners. There is little doubt that the greater part of the Portland cement now manufactured is made from dry raw materials of the limestone and shale class; the second largest source is from wet raw materials of the chalk and clay class. One special raw material is blast-furnace slag, which is mixed with limestone and burnt to make Portland cement. The product, from its origin, has acquired the name "Eisen Portland Cement" in Germany, but there seems no good reason why it should be distinguished by any qualification. If properly made of suitable acid and basic oxides, Portland cement is Portland cement whatever may be the origin of its constituents or whatever their previous state of combination may have been. The second great group consists of so-called "natural" cements, by which is meant hydraulic cements made from raw materials which occur in nature, mixed in approximately correct proportions, and prepared by burning such materials without previous mixing or addition. Roman cement is typical of this class; American natural cements belong to the same division, but may be regarded as a separate group on account of their frequent high content of magnesia. The use of natural cements is declining relatively to the total consumption of hydraulic cement, as is shown by the following figures:—In 1904 the world's output of natural cement was about 1,000,000 tons, as against 11,000,000 tons of Portland cement. In 1886 the respective figures are 600,000 tons of natural cement and 2,500,000 tons of Portland cement. It will be seen that whereas the output of Portland cement has more than quadrupled in the period under discussion, the output of natural cement has barely doubled.

This change is due to the cheapening of Portland cement and to the growing understanding that a carefully manufactured product with its composition chemically controlled is in many respects preferable to a material which from its origin and mode of preparation must vary according to the natural fluctuations of the raw material. There is still a considerable field for natural cement at the place of its production, but on account of its mediocre quality it will not bear much freight; and it may be safely predicted that in cases where it is practicable to establish a manufacture of Portland cement, using the raw materials formerly employed for making "natural" cement, this change in the industry will occur. It has already occurred in the Cambridge district, where formerly natural cement was made, and now is replaced by Portland cement of excellent quality. The recognition of the necessity for intimate admixture of raw materials, even when of approximately correct composition, has been commented on above.

The present position of the trade in hydraulic lime is not quite similar. It is true that hydraulic lime is being steadily replaced by Portland cement for most purposes, but there are some uses in which it still holds its ground. Moreover, there are some deposits, such as those of Theil,

which could not easily be utilised for making Portland cement, because they contain so little alumina that no ordinary clayey material would bring their composition within the limits proper to Portland cement. The fact that a true hydraulic lime can be slaked and used after a long time, and that its ultimate setting is very deliberate, is of advantage in some engineering operations.

The utilisation of blast-furnace slag for the manufacture of cement is of more than a little interest. One direction in which blast-furnace slag is employed is to produce Portland cement by burning with a suitable proportion of limestone, and has already been mentioned. Another is the production of a puzzuolanic cement by mixture of granulated blast-furnace slag with lime; this mixture at one time assumed some importance, but is now not largely made; about 350,000 tons was manufactured in 1903. A third mode of turning blast-furnace slag to account is of more modern and immediate interest, and needs somewhat closer description. About six years ago, Dr. Passow, of Hamburg, discovered that when blast-furnace slag containing a fairly high percentage of lime, *e.g.*, 40—45 per cent., was cooled in a regulated manner, so that in passing from the liquid to the solid state it was reduced to a granular condition, it underwent a surprising modification of its properties. Whereas the slag, when run from the blast furnace and allowed to cool in blocks, or when granulated in water, as is done in making puzzuolanic cement, exhibits only the feeblest tendency to set, yet on being treated in the way mentioned so that the rate and mode of cooling can be controlled, this same slag when finely ground will set and attain a strength comparable with that of Portland cement. It is an advantage to add a small quantity of Portland cement, say 10 per cent., but this addition has no sensible influence on the strength of the product, its function being merely to cause the material to set more rapidly than the slag will set by itself. When asked to investigate this process I felt somewhat sceptical as to the correctness of these statements; but as a matter of fact experiment showed that they are accurate, and it must be accepted that it is practicable to prepare hydraulic cement of great strength from suitable blast-furnace slag by the regulated cooling of the slag while solidifying. A good deal of this Passow cement has been made in Germany and in the United States, and a considerable amount has been prepared in this country. A cement of this kind, on account of its cheapness and the fact that it is made from a material which has been actually fused, and, therefore, must be homogeneous and free from uncombined lime, has noteworthy merits, and should occupy an important position among cements for structural purposes.

There is another cementitious material, the present position of which calls for comment. This is puzzuolana, using the term in its widest sense. Although the oldest of all materials by aid of which hydraulic cement can be prepared, it has of late years fallen somewhat into the background, because of the great growth in importance of Portland cement. But it has uses of its own, and there are signs that these are beginning to be better understood. For example, in places where there is a supply of lime but no suitable argillaceous material for preparing Portland cement, it may be advantageous to convert the lime into an hydraulic cement by mixing with it some form of puzzuolana, such as trass or granulated blast-furnace slag, which may be imported more cheaply than Portland cement. A much larger use is as an addition to Portland cement concrete. It is well known that when Portland cement is hydrated in setting, a large part of the lime which it contains becomes liberated as calcium hydroxide, which may, under some conditions, be a source of weakness. If an active siliceous material such as a puzzuolana is added, it combines with this lime and forms with it a cement as useful as the Portland cement itself. As the use of puzzuolana turns the useless and superfluous lime into a valuable cementing material, its addition is of particular value for marine work, where resistance to the known destructive action of sea-water depends primarily on the closeness of texture of the concrete, and the absence in it of any material such as uncombined lime, which reacts easily with the magnesium salts present in the sea-water. At the present time these advantages are not so generally recognised as would be expected, and the production and use of puzzuolanic materials is not very large.

There is, however, evidence that a better understanding of the true functions of these substances is developing, and the demand for trass and its congeners may be expected to increase. That the older engineers fully understood the value of puzzuolana is shown by the following passage from Smeaton (1791):—

"On this subject I was already apprised that two measures of quenched or slaked lime, in the dry powder, mixed with one measure of Dutch Tarras, and both very well beat together to the consistence of a paste, using as little water as possible, was the common composition, generally used in the construction of the best water-works both in stone and brick; and which, after being *once set*,* would afterwards become hard, without being completely dry; nay, that it would in time grow hard, even under water."

"Having heard of a lime produced from a stone found at Aberthaw, upon the coast of Glamorganshire, that had the same qualities of setting as Tarras, I was very anxious to procure some of the stone; which I did, and burnt it into lime. I found it to require a good deal of fire to make it, by quenching, fall into a fine powder. This stone, before burning, was of a very even, but dead sky blue, with very few shining particles; but when burnt and sifted it was of a bright *buff colour*. Having made up a couple of balls, according to each of the former proportions, and also a couple of balls with common lime (by which I mean Plymouth lime), the difference of hardness after 24 hours was very remarkable; the composition of two measures of Aberthaw to one of Tarras considerably exceeded in hardness that of common lime and Tarras in equal parts. The composition of Aberthaw and Tarras in equal parts was still considerably harder, and this difference was the more apparent the longer the compositions were kept.

"The Puzzuolana is also a porous substance, and, like the Tarras, produces no effervescence with *aqua fortis*; it has much the appearance of being a volcanic production, is of a brown colour, and, as my friend, Mr. Cookworthy, told me, contains iron; it has the look of an iron ore rendered porous, or burnt to a cinder by fire. It is said to be found in large quantities in the neighbourhood of Mount Vesuvius, and in several other parts of Italy. That which was the subject of my experiments, as well as the best of what I have since caused to be imported, or have seen, was from Civita Vecchia. I have seen a kind of puzzuolana said to be brought from Naples, of a less ruddy and more grey colour, but on trial I did not find it to be near so strong as the former, for one-half of the quantity from Civita Vecchia would cause a composition of calcareous mortar to set harder in water than that from Naples would do. It is said that the ancient baths and water-works of the Romans were built with this kind of mortar, and their duration has, it seems, proved the validity of the composition; but I apprehend, unless they have the Lyas limestone in Italy,† it was reserved to the Eddystone to have those two materials first combined, and of consequence, so far as has yet appeared, the perfect composition of water mortar was now first ascertained to be a proper mixture of blue Lyas lime and puzzuolana."

A word may be said as to a product which is of future, if not of immediate, interest. This is white Portland cement. There is no cement suitable for external use which is white; all the ordinary white cements are of the plaster class, and, although excellently suited for interior work, fail when exposed to the weather, because of the fact that calcium sulphate is a soluble salt. There is a large field for a cement capable of resisting moisture, and of lending itself to decorative effects as easily as Keene's. At first sight it would seem that nothing could be easier

* "This is the term used in the application of calcareous mortar, which denotes its first step, or degree of hardening; but in this state, though it has lost its ductility, it is a very friable substance."

† "Lyas is the general term for strata of stone of the species of Aberthaw, in several countries."

then to supply this architectural requirement. It is well known that the colour of Portland cement depends on the oxide of iron which it contains, and it is also known that the iron compounds contribute little to the strength of the cement, and are not essential in inducing proper combination of the acid and basic oxides during burning; they can be replaced by corresponding compounds of alumina, and these are white. It follows that to make a white cement identical in its mechanical properties with Portland cement, all that is required is to use raw materials free from iron, and to prevent the introduction of iron from the fuel or grinding apparatus. It is not difficult to obtain raw materials that contain mere traces of iron, and it is quite practicable to avoid this contamination during manufacture, and after a few trials Portland cement very nearly white can be prepared. But as the colour approaches white, the influence of various small impurities becomes apparent, and to obtain a true Portland cement approaching Keene's cement in purity of tint is not quite an easy matter. Still, it has been and can be done, and a product prepared admirably adapted for ornamental purposes.

I now come to the second part of this paper, namely, that dealing with the advance in methods of control which has taken place during the last 20 years. This advance has naturally taken place *pari passu* with the improvement in manufacture, the two being so intimately interwoven that they have acted alternately on each other as cause and effect. Perhaps at the beginning of the period, say, in 1886, as there was about that time a considerable increase in the frequency with which tests were applied and an increase in the reliance placed on them, improvement in manufacture owed a good deal to the greater activity in testing; more recently the rate of improvement in manufacture has been at least as great as the rate of improvement in testing, and some of the alterations for the better in testing have been made in order that the system of testing may be sufficiently searching and exact correctly to appraise modern cements, the great bulk of which are excellent, and some even a little ahead of present demand, though not of present need.

It is interesting to compare a specification of 1886 with one now current, and for that purpose I have chosen one much used at the former date, and have placed it in company with the British Standard Specification as at present used. These are given in Appendix B.

It will be seen that the improvement is great. The points of chief importance are the increased fineness required, the specification of a proper chemical composition, and the insistence on a quantitative test for soundness. Incidentally there is, in the later specification, recognition of the fact that a sand test in necessary, and there is created a beautiful blank by the abolition of that monstrous survival, the weight per bushel test. Cement faithfully complying with the British Standard Specification, is some 100 per cent. better than a cement which complied without much margin with the 1886 specification, and is about 30 per cent. cheaper.

But although the current British specification is in all respects an improvement on its forerunners, it is not to be considered a perfect document. As one who had some part in producing it, I admit this freely, but I say without reservation that it has proved to be a useful working compromise, satisfactory in the main to the great bulk of consumers and manufacturers. No doubt there are clauses which may stand in need of modification or amendment, and recognition of this is shown by the impending re-assembly of the committee to prepare a revised edition.

Quite apart from this matter of revision, I may perhaps be allowed to indicate the direction in which the specification of the future should be carried.

To begin with, neat tests should be abolished. Sand tests should be on a weaker mixture than 1:3, and the sand should be finer; quite possibly a sand of much greater variety of grain, approximating to an ordinary building sand, might be made the standard. The tests for fineness and soundness should be a good deal more rigorous than at present, and the stipulations as to chemical composition should be extended to the limits defined by modern knowledge. With a specification constructed on these lines, cement in cases of urgency might be passed on its soundness, fineness, and chemical composition, leaving its mechanical strength for determination at leisure.

Improvement in the *nature* of methods of testing has not been great. There has been a substantial improvement in the application of well-known processes such as the customary mechanical and chemical modes of evaluation, but there has been little alteration in essence. For example, there has been no successful attempt to appraise cement from its proximate composition, although that is the natural and right method of deciding its quality.

The most pressing and practical of all the questions relating to the composition of cement is the determination of what is called "free lime," and many have been the prescriptions put forward for the purpose. On examination all fail, and there is at the present time absolutely no method of determining by any chemical process whether a given cement contains free lime or not. There is no known method of dissolving "free lime" from cement without acting on the somewhat labile calcium compounds which constitute the cement itself. A clever attempt on different lines was made by Keiser and Forder, which consists in treating the cement with a small quantity of water with the view of completely hydrating the lime, and driving off any excess of water which may have united with the calcium silicates and aluminates, by heating to a temperature of 185° C; this temperature is chosen as being below the temperature of decomposition of calcium hydroxide, while above that at which the water not combined with full lime is expelled. I carried out a series of experiments with this method when it was published and abandoned it with some reluctance. Its radical defect appears to be that, under the prescribed conditions, a portion at least of the calcium silicates, aluminates, and ferrites are decomposed, and yield calcium hydroxide, which, by this method, is of course counted as if it had been derived from the hydration of CaO itself.

Fortunately, although it has hitherto been found impracticable to determine "free lime" chemically, the evil effects which its presence involves can be detected mechanically with simplicity and certainty. The old-fashioned cold water pat test for soundness is happily obsolete, and the various forms of hot test which depend on qualitative observations, and whose results are expressions of opinion and not of measurement, may be reckoned obsolescent. Of quantitative soundness tests there are two which, used at an appropriate temperature, give excellent results, namely, the Bauschinger and the Le Chatelier tests. The whole subject was investigated by a Committee appointed by the International Society for Testing Materials. As Chairman of that Committee I had the duty of collating the results obtained by my colleagues in their examination of the merits of these tests. The figures showed incontestably that admirable data could be obtained by either method. On the ground of its greater simplicity, the Le Chatelier test was preferred, and although I hold that the direct method of measurement in the Bauschinger apparatus has much to recommend it, yet I concur fully in the preference expressed by the Committee for the use of the Le Chatelier test in every-day work. Partly as the result of this inquiry, the Le Chatelier test has become general in this country, and is prescribed in the British Standard Specification. It constitutes a valuable safeguard against the production or acceptance of unsound cement, and represents one of the most notable improvements in methods of testing in recent years. Messrs. Dounan and Barker have recently devised a method for determining the total dilatation of cement, which for laboratory use may be of much service.

In the period of which this paper treats much progress has been made in a knowledge of the chemistry of cement. Prior to 1886 there were many conflicting theories and little real knowledge. The condition of things may perhaps be judged that at so recent a date it was possible to put forward an hypothesis cited by Le Chatelier in the delicately ironical words:—"M. Mercerom has proposed an entirely original theory which attributes the hardening to the desiccation of the clay under the influence of the heat disengaged by the hydration of the lime." It was Le Chatelier himself who, in 1887, first communicated a

definite statement based on sound experimental evidence as to the chief compounds present in Portland cement, and added to that a coherent explanation of the principal changes which these undergo when cement sets. Since then other chemists, notably the Newberrys, have extended and consolidated this work, and recently also Clifford Richardson.

The two chief methods which have been successfully employed in investigating the chemistry of cement are the synthetic and the microscopical. All analytical methods have failed, as they have failed when applied to the determination of the proximate composition of natural rocks. By synthesis three calcium silicates, $CaOSiO_2$, $2CaOSiO_2$, $3CaOSiO_2$, have been prepared and are recognised as individual bodies; the four aluminates, $CaOAl_2O_3$, $3CaO_22Al_2O_3$, $2CaOAl_2O_3$ and $3CaOAl_2O_3$, have similarly been prepared and identified. It is generally accepted that of these, tricalcium silicate, $3CaOSiO_2$, is the essential constituent of Portland cement. The constituent of next importance is a basic aluminate, but there is still some difference of opinion as to whether this body should be represented by the formula $3CaOAl_2O_3$ or $2CaOAl_2O_3$. The remaining silicates and aluminates are of minor moment, and their presence in Portland cement clinker may be regarded as due to the natural imperfection of the raw materials employed and the limitation of the means of uniting these raw materials under the conditions of manufacture at present obtaining; in short, if a mixture of tricalcium silicate and tri- (or di-) calcium aluminate in suitable proportions could be industrially prepared, it would be an ideal cement. The silicates and aluminates going to make up commercial Portland cement clinker, whether essential or subsidiary, are not necessarily present in the clinker as separate individuals. There is good reason to believe that they exist as solid solutions, and that these solid solutions may have been mingled whilst the clinker was plastic, and have separated out when it cooled. The two chief minerals which have been recognised in cement clinker have received the names alite and celite, and according to the best current knowledge consist respectively of a solid solution of tricalcium aluminate in tricalcium silicate, and one of dicalcium aluminate in dicalcium silicate. Of these two substances alite alone is of value in the setting of the cement. It is generally accepted that in normal Portland cement clinker containing only moderate quantities of ferric oxide, magnesia, and alkalis, these minor constituents play quite a subsidiary part. No doubt they contribute to the fusible magma from which the main minerals crystallise, but the fact that what is truly Portland cement can be prepared from materials in which they are absent is sufficient proof of their relative insignificance. Whether any modification of this very clear and simple view of the constitution of Portland cement clinker may later be found necessary or not, it is in my judgment the nearest approach to the truth yet obtained, and on account of its philosophic basis, no less than because of its experimental foundation, it is as far in advance of the explanations current 20 years ago concerning the chemistry of cement as the manufacture of to-day is ahead of that at the same earlier date.

It will be observed that this theory does not necessarily apply to cements, such as Roman cement, less basic than Portland cement, or containing substantial quantities of constituents which are subsidiary in Portland cement, as, for example, natural cements rich in magnesia. Each of these will have to be examined on its merits, but although the inquiry will be far from a repetition of the Portland cement investigation, yet its successful prosecution will be greatly aided by the knowledge already at our disposal.

Correspondingly with the establishment of a good working hypothesis of the constitution of Portland cement clinker, has grown a reasonable explanation of the chief changes which occur when Portland cement sets, and it may fairly be said that this explanation has been reached during the period with which I am dealing. The underlying idea is derived from researches on the setting of plaster of Paris which is known to be due to the dissolution of a more soluble form of calcium sulphate and the deposition of a less soluble form in felted crystals, the dissolution and deposition being successively accomplished by the agency of a quantity of water small relatively to the mass of solid matter dissolved and deposited. This idea can be applied to those constituents of Portland cement which are soluble in water and will form hydrated crystalline products, provided that the substances dissolved have a transient greater solubility than the substances deposited. Now, in Portland cement the most important constituent, alite (*i.e.*, a solid solution of tricalcium aluminate in tricalcium silicate), is affected by water; and celite, the second large constituent, is but little influenced. Alite when acted on by water is decomposed according to the equation:—

$$n[2(3CaOSiO_2)]+m[3CaOAl_2O_3]+n[9H_2O]+m[12H_2O]=n[2(CaOSiO_2)5H_2O]+n[4CaOH_2O]+m[3(CaOAl_2O_3)12H_2O],$$

n and m being written in merely to recall the fact that alite may contain various proportions of its two components, tricalcium silicate and tricalcium aluminate. It is believed that the tricalcium aluminate, once liberated from its solid solution in tricalcium silicate, goes through the stages of hydration, dissolution in a more soluble form, and deposition in a less soluble form, by the action of a relatively small quantity of water as an intermediary,* precisely as does hemi-hydrated calcium sulphate when plaster of Paris sets. The behaviour of the tricalcium silicate is not quite so simple. On liberation from its solid solution it is decomposed, yielding hydrated monocalcium silicate and calcium hydroxide. Both crystallise and form a hard coherent mass. It must be assumed that one or both substances possess two degrees of solubility if the plaster hypothesis is to be used. Unfortunately, there is not, as far as I know, any direct evidence on this question. The dual solubility of hydrated monocalcium silicate has not been established, and that of calcium hydroxide, though it exists, is dependent on alteration of temperature, and is not a transient phenomenon occurring at the time of dissolution. It is possible that these two substances are mutual solvents, and communicate to each other the necessary property of transition from a higher unstable solubility to a lower stable solubility. If no proof of this is forthcoming, the plaster theory may have to be displaced.

Precisely as in the case of the constitution of clinker, so in that of the setting of cement derived from it, no serious attempt has been made to deal with other cements than Portland. The setting of that noteworthy product, Passow cement, to which I have already alluded, has not been explained, and is certainly worthy of study, if only for the fact that it is accompanied by the combination of a proportion of water so small as to appear quite inadequate for hydration.

There is an ample field for investigation, and, with the present-day view that the manufacture of cement is a great chemical industry, workers will be forthcoming, properly trained and equipped, and in adequate numbers, to carry to a fruitful conclusion researches whose outlines I have endeavoured to indicate.

In the foregoing part of this paper I have endeavoured to sketch the progress which has been made during the last 20 years in the methods of manufacture, in the methods of controlling and appraising the quality of the product, and in knowledge of the chemical changes concerned in the production of cement clinker and in the setting and hardening of cement. I may now, perhaps, be permitted to indicate on what lines, in my opinion, further progress is likely to be made, gathering together the statements on the question which have been made as commentary on particular aspects of the question.

It is practically certain that the distribution of the industry will continue until every considerable centre of trade will have its local supply of cement. It is equally probable that the consumption of cement will increase at a rapid rate. Unless and until it is replaced by an equivalent cementitious material, it will become the standard binding agent and will gradually displace lime for all ordinary building operations. In addition, it is

* I do not know whether any direct experiments on this point have been made.

more than likely that there will be a great development in the use of armoured concrete, which from its monolithic character is admirably fitted for massive and permanent structures, especially such as must be fireproof. Concrete, by itself, or reinforced with steel, will become the most important of all structural materials, and will be the one to which the builder turns naturally when first considering what method of construction to adopt in any given case. Huge quantities of cement will be needed for the preparation of this concrete, and that cement must, if possible, be a good deal cheaper than it is now.

Several improvements, not involving any great change in existing arrangements, though necessitating some departure from current practice, may be expected. The first, and perhaps the most important, is the drying of wet raw materials before mixing. At present water is added to these wet materials so liberally that approximately twice as much water as is naturally present has to be driven off. There are certain practical reasons why it is easier to work with a slurry than to abolish the preparation of slurry, to dry the chalk and clay, and to mix them precisely as limestone and shale are mixed in the dry process; but in my opinion the advantages of working by the dry method are so substantial that they will lead to its adoption. Another direction in which improvement is to be looked for is the better utilisation of the waste heat of the kilns. The total number of heat units escaping is enormous, and in the case of dry raw materials the temperature of the waste gases is relatively high. A good deal of saving should be effected by using these gases either direct under a boiler or in a producer.

Whatever may be the details of operation, the fundamental necessity for finely grinding and intimately mingling the raw materials remains, because at the temperature of a rotatory kiln the clinker is merely plastic and the acid and basic oxides can only unite slowly. If the plasticity is modified so that the mass is a little more fluid, the rate of union will be increased and the size of the particles may be larger. To reap the full benefit of the greater mobility of the particles at a high temperature, the whole mass must be fluid. As soon as this state is reached the need for grinding the raw materials disappears and the rotatory kiln becomes an obsolete machine. In the furnace of the future the raw materials without grinding, or mixing, perhaps without even drying, will be tipped in by the truck-load, and tapped out as liquid Portland cement.

There is no physical difficulty in fusing Portland cement. Years ago Michaëlis fused the raw materials in an oxyhydrogen blow-pipe flame and obtained an excellent product containing 70 per cent. of lime and perfectly sound, and at the present time no competent experimenter would hesitate to undertake the preparation of fused Portland cement in quantity if he were not too seriously restricted in expenditure of money. But to pass from this experimental achievement to the manufacture of fused Portland cement is a step of some magnitude. Several attempts have been made, notably by Messrs. Hurry and Seaman, to adapt the blast furnace to this end. A blast furnace is an ideal apparatus for the purpose, because it is a fairly efficient thermal device, is of simple construction, and can handle large quantities of material; it also has sufficient capacity to ensure tolerable uniformity of product in spite of moderate irregularities in burden. Unfortunately, the temperature normally attainable in a blast furnace is below the fusing point of clinker, and some modification must be made to reach and surpass this point. In the Hurry and Seaman process the temperature is raised by working at a pressure of 10—20 lb. above that of the atmosphere, the furnace necessarily being closed so as to prevent the waste gases escaping below this pressure. Evidently this is a device to increase the partial pressure of the oxygen in the air injected, from 0·2 atmosphere to 0·33—0·47 atmosphere, which moderate increase proved to be sufficient to fuse clinker somewhat low in lime. As the lime content is raised the clinker becomes less fusible, until at the saturation point, represented by the equation—

$$\frac{CaO}{SiO_2 + Al_2O_3} = 3,$$

a temperature greatly above that obtainable in an ordin blast furnace is needed. Therefore, if the Hurry a Seaman system is adopted the furnace must be work under a somewhat heavy pressure, which may invol difficulties in constructing an apparatus capable at or of remaining tight to this pressure and of supporting t high temperature necessary. An alternative is to increa the partial pressure of the oxygen by using a gas rich than air in oxygen. This seems to me a possible solutic but at present the cost of air enriched in oxygen is t high for its use in the manufacture of so cheap a mater as cement to be practicable.

There remains the method of raising the charge to temperature somewhere near its melting point by a bla of air at the ordinary pressure or at the highest workal pressure (and, of course, at the highest feasible tempe ture), and then completing the raising of the temperatu to the fusing point of the clinker by some other metho To introduce a limited quantity of air rich in oxyg below the plane at which ordinary air is injected mig serve if sufficient fuel remained at this point to be utilis by the extra oxygen; should that be already burnt, fu would need to be injected together with the enriched a Quite possibly the secondary heating could be don electrically; the heated charge in a semi-plastic sta would descend into the crucible of the furnace, where i temperature would be raised to its fusing point. Agai the difficulty in realising this possibility depends on t fact that cement is terribly cheap.

However it may be accomplished, the commerci preparation of Portland cement by fusing the raw materia together is the task now before the manufacturer. Th advantages are substantial. Every kind of raw materi —sandy clay, flinty chalk, irregular limestone—can b used provided that the ultimate composition of the whol charge is correct. All need of preparation of these ra materials is abolished. The materials are tipped in b the same wholesale methods that obtain with a blas furnace. A single furnace will give the output of a good sized factory. The proportion of the raw material can be so adjusted that the fused cement will be of pre cisely calculated composition, approaching theoretica perfection, and, from its mode of preparation, absolutel sound. It can be granulated by air or steam so that i is readily ground. The whole process of manufactur will be reduced to a simplicity not easy to surpass.

Until that new era comes we must accept what progres has been made, and certainly there is no cause for dis content. The very appearance of a modern works with well-kept machinery, dust-removing appliances the kilns kept almost like engines, and the engines kep like a gun, is a sufficient contrast with the wonderful ol collections of tumbledown sheds full of discarded mill stones and toothless harrows, and having nearly as much cement on the floor and in the air as was in the warehouse where clinker grit formed a large percentage of the lubri cant, and which were provided with power by an asthmati prime mover easily recognisable as a steam engine by mar observation of any gland or joint. The systematic and business-like control of a modern works, the high technical equipment of its staff, the constant resort to scientific methods of inquiry, are equally distinctive, and of even greater importance for the successful prosecution of a vast and growing chemical industry. I venture to think that whilst that spirit of investigation and enterprise, which has done so much during the last 20 years, continues to prevail, progress will be continuous and of solid advan tage to the consumer and producer alike.

APPENDIX B.

Specifications for Portland cement.

	1886.	British Standard, 1904.
Fineness :		
On sieve 50 by 50..	10 per cent.	—
76 by 76..	—	3·0 per cent.
180 by 180..	—	22·5 per cent.
Specific gravity :		
At works	—	3·15
After delivery	—	3·10
Weight per bushel	116 lb.	—
Soundness	Pats warmed and watered.	Le Chatelier test. Expansion after 24 hours—12 mm. Expansion after 7 days' aeration—6 mm.

	1886.	British Standard, 1904.
Tensile strength:		
Neat 1¼ by 1¼—		
2 days	350 lb.	—
4 days	500 lb.	—
7 days	750 lb.	—
1 by 1 section—		
7 days	—	400 lb.
28 days	—	500 lb.
3 Sand, 1 cement 1 by 1:		
7 days	—	120 lb.
28 days	—	225 lb.
Analysis	—	Required.
Bulking	Required.	—

Discussion.

The Chairman suggested that, as Mr. Blount had indicated that the Standards Committee was to meet very shortly, it would be well if some competent authority were to make suggestions on that head, which would certainly receive consideration at the hands of the Committee. They would also like to hear any views as to the possibility of the future improvements to which allusion had been made.

Mr. J. L. Spoor said he thought up to the present time a rotary kiln could not burn a ton of cement with so low a percentage of fuel as the best form of vertical kiln. A few months ago he examined Mr. Edison's rotary kiln at his works at Stewartsville, N.J. It was 150 ft. long, and he had seen it make 1000 tons a week of excellent cement. It was a dry process, and was using under 17 per cent. of fuel, which was the best record in the world. At the present time English practice could not compete with that, but of course it must be remembered that we were dealing with rather different materials. The materials they had in the Lehigh valley were exceedingly well adapted both for grinding and burning cheaply. Then there was a vertical kiln which was taking its raw material in the shape of bricks, or pieces of dry slurry, and would burn it into excellent clinker of a specific gravity as high as the rotary kiln on 14 per cent. of fuel. Of course the rotary kiln had come to stay. If the cement trade was going to move into districts where the cement was to be used, the plant would have to be adapted to the raw materials and fuel most easily obtained on the spot. At present the rotary kiln held the field, and was likely to. With regard to the Standard Specification, he did not quite know on what principles it was framed. It looked very much like a compromise, and not a scientific standard. Some of their friends were a little bit worried about magnesia, as to which he was not quite orthodox. There were cements made out of dolomite which behaved very well for a number of years, even better than Portland cement, so that one got a little bit sceptical about the various theories as to the evil of magnesia. But at any rate he did not know why the Standard Specification Committee drew the line at 3 per cent. In other countries the question had formed the subject of inquiry by Commissions of cement manufacturers and engineers. They drew the line at about 4 per cent. It was an open question, and if it was a hardship pressing on some makers it ought to be proved that cement having above 3 per cent. ought not to be put on the market before adopting a Standard Specification. The question of the use of puzzuolana had been prominent for many years on the Continent, and there were two schools of opinion. Michaelis told them that it would be a very good thing to use trass as an admixture with cement, especially for use in sea-water, but he hoped that before it was done they would carefully consider by whom it was to be done, and in what quantities, and not before they had thoroughly proved that it was in itself desirable. He doubted its advantage, and was afraid it would lead to adulteration.

Mr. H. K. G. Bamber asked the author for his reasons for hoping that the wet process would become obsolete. He knew that, from the manufacturing point of view, with many materials it was much easier to produce a more perfect mixture with the aid of water as a medium than to grind the dry materials together. Speaking with some knowledge of that point, it seemed that the wet process was very effective in that respect, inasmuch as the common practice was to reduce the raw materials to such a fine state of subdivision that 97 or 98 per cent. of the whole material was capable, before leaving the mixing machine, of passing through a sieve of 32,400 holes to the square inch, and that calculated on the dry materials. Of course the difference between the wet and dry process only applied to that part of the process previous to calcination. The author told them something about the action of the fuel ash in the ordinary or chamber kilns, and referred to the sulphur compounds which were present in some form or other, which had the effect, either by becoming mechanically mixed or chemically combined during calcination, of producing a somewhat more slow-setting cement than that manufactured by the rotary process. Could the author tell them whether the presence of sulphur in some form in the cement, probably in the form of sulphates, would be equally effective in slowing the material, if it were present in the clinker derived from the sulphur compounds present in the raw material, as if the same were derived from the fuel used for calcining? An instance had come before him recently in which, by selecting portions of clinker from an ordinary chamber kiln, which had clearly not been contaminated with any fuel, ash, or dust, and by grinding those portions and analysing carefully, he found that clinker taken from four or five different chamber kilns, manufactured at different works, were all practically free from fuel ash, but varied in the content of sulphate (SO_3) from 0·3 up to 1 per cent. All these clinkers, when mixed with water, even to the extent of 35 per cent., had an initial set of about five seconds, and an increase of temperature of about 20° F. in five minutes during the completion of setting, which was about that of a clinker burnt in a rotary kiln, where the ash did not contaminate it. Again, Mr. Blount referred to the great importance of reducing the raw material to an extremely fine state, which was well known to cement manufacturers. A case came before him recently in which a material which contained a very large percentage of sand was mixed with chalk in the right proportion to make a good Portland cement clinker. It was burned in a rotary kiln, and the clinker, which was excellent in appearance, was entirely soluble in acids, the whole of the sand, which was in particles of considerable size, having under these circumstances become combined; but the clinker, or the cement made from it, was quite unstable, and not volume constant. Was it possible that portions of silica on the surface of the particles of sand might by intimate contact with the lime present become tri-calcic silicate, whereas a portion somewhat nearer the interior might only have become di-calcic silicate, and the portion in the interior, mono-calcic silicate? Was that a possibility? Because, if so, the mixture of those three substances, although all soluble in acids, might be the cause of the unstable condition of that particular clinker. Reference had been made to a new apparatus brought forward before this Society at Liverpool, which determined the expansion of cement, which he believed was that of Professor Donnan. He had had an opportunity of trying its accuracy, and it appeared to him that there was a great difficulty in connection with it, inasmuch as the mercury, a material of such high specific gravity, did not appear to penetrate into the cavities of the briquette or block that was being tested, with the result that there was a certain amount of expansion on boiling the block; and if there were cracks, which probably there would be, the mercury did not find its way into them, and therefore an accurate measurement of the expansion of that particular cube was not obtained.

Mr. Gilbert said as regards the automatic handling of the material, with the exception of the rotary kiln, he rather thought the upper diagram had the advantage. In the lower diagram there was a great deal of handling at different stages, the whole of which [illegible] be dispensed with, which would effect a saving of about 1s. a ton. With regard to the saving in the cost of manufacture

from the rotary kiln, as compared with the Schneider kiln, he put it at about 2s. 6d. a ton. As to the mechanical difficulties connected with the rotary kiln, he had been mainly concerned with kilns built by German firms, and one defect was that the cooler was made too small in diameter. In one making about 1¼ tons of clinker per hour, which took 28 per cent. of coal, there should be about 3000 cb. ft. of cold air going through per minute, to cool down the clinker, and support combustion, but in all the experiments he had made, he had never found more than 1000 cb. ft. per minute of cold air enter the clinker cooler. The effect was not so much that the clinker did not get cold, but the end of the cooler got red hot, and its life became very short. Another difficulty was the deposit of a large quantity of coal ash and raw material dust in the flues. The actual length of kilns working on the dry process depended on the amount of moisture in the raw materials, if the waste gases were used for drying in separate drums. He had found 60 ft. satisfactory when the moisture amounted to 16 per cent., but in materials containing only 3 or 4 per cent., he thought the kilns might be 90 to 100 ft. long, and the waste gases would still have sufficient temperature for drying purposes.

Mr. W. F. Reid said he thought the contrast drawn between the practice of 1886 and the present time was a little exaggerated. For instance, the use of hand barrows was not universal in cement manufactories in 1886. He himself in 1870 put up trucks for delivering the stuff at the top of the stone crusher. With regard to the specification quoted, he could only say that any engineer who had such a specification in 1886 was justified in not allowing his name to be published. The specification of Mr. Grant, of the Metropolitan Board of Works, which was the standard specification in the trade, even in the sixties, and certainly before 1870, was far preferable. He mentioned that, so that it might not be supposed that these points in 1886 really were, as they were represented to have been, the general practice in this country. Our great competitors, the Germans, had preceded us in the scientific testing of materials. In 1869, there was no cement manufactory in this country that tested its raw material chemically. He brought over the first carbonic acid apparatus. Dr. Michaëlis at that time fused a piece of cement so highly limed, that it raised his astonishment that it did not "fly." The reason was a very good one. Fused cement did not set at all. They could get cement fused in a kiln if enough fuel were put in; and it ran through the bars; but the custom was to throw it away because it would not set. One might, perhaps, thus produce a setting cement; but the fact that one of the most highly trained scientific men who had tried fused materials since 1870, and had not succeeded, rendered this improbable. He did not himself think that the fusing of materials in that way would produce economically a good Portland cement, or that the process would be one which would be advisable in any way as regarded the material. When the materials were fused, it was by no means certain that they were homogeneous. There was another more hopeful way he thought. The composition of the slag from some of the blast furnaces in the United States was now being accurately proportioned for the purpose of making cement. At the late Congress of Applied Chemistry in Rome, he learnt that what the Americans chiefly worked for now was not the iron but the slag, which they made into cement and carefully proportioned the materials so that they should get slag suitable for cement making. Apparently the iron was now becoming a by-product, and the slag was the chief product. With regard to the puzzuolana, that was a very important product in some countries, but in this country he thought the question of transport was altogether against it, as they had to use a large proportion of it. In the ashes recently ejected from Vesuvius, nature had supplied them with a new material which he had tested and found hydraulic; 60 per cent. was soluble in hydrochloric acid. With regard to the tests at the present day, he thought there was an opening for some modification. The fineness was undoubtedly the one thing the consumer wanted. If he got that, he could utilise the cementitious properties of the product to the highest degree, and the finer the cement the greater the trade would be. Although perhaps the manufacturer might object to greater fineness, yet, if he could only increase the demand and supplant ordinary lime, he would be working to his own interests. He should have liked to have heard something about the very extensive plant put up by Mr. Edison in the States. He had taken the whole cement industry in hand and remodelled it, and started cement works. When he was in the States he endeavoured to see them, but was unable to do so, and if any gentleman present had been there it would be very interesting to hear something about them.

Mr. Friswell said he should like to say a few words on behalf of a man who was long dead. In the year 1887, he wrote an article in the "Engineer"* on the process of burning cement in a cylinder, which had been published in the previous year by Mr. Frederick Ransome. Mr. Ransome had nearly ruined himself in endeavouring to get this process introduced, and in that year he had succeeded in getting a kiln at work at Messrs. Gibbs' Works at Grays. He went down and saw that kiln. It was an iron cylinder 25 ft. long and 5 ft. in diameter, lined with fire brick, fired by means of small Siemens producer, about 3 cwt. per hour, and was supplied with regenerative chambers, so that the waste heat from the kiln was returned to it. Ransome was making cement then at the small rate of something less than 1 ton an hour, but it was quite successful, and good cement was produced. He spent many months after that in endeavouring to get it taken up here, but in vain. It was not until the invention had travelled to the United States, was adopted there, and had then been brought back again, that the matter became interesting to English manufacturers. It was a sad story, but one which ought to be put on record.

Mr. A. O. Trechmann said he agreed with Mr. Bamber that no better method of bringing the raw materials into close combination than the wet method could be devised, and he would like to know the reason of Mr. Blount's preference for the dry process. It could scarcely be on the score of smaller fuel consumption causing less contamination of the purity of the product through coal ash, because in the rotary kiln, as Mr. Blount stated, practically all the coal ash went up the chimney. There was one serious objection to the dry process with rotary kilns. In America, round about the dry-process works, the country was coated with a covering of dust, which was anything but pleasing to the neighbours. With regard to the setting time, Mr. Blount seemed to consider it was very easy to bring rotary burnt clinker to the required setting-time by the addition of water, but he thought in practice it was not so easy. The ash of the fuel used in the fixed kiln acted as a useful retarding agent in the setting process. If clinker were taken quite free from impurities of that kind, the setting time was a difficulty. It was therefore very useful to mix the clinker from a rotary kiln with that from a fixed kiln; the product might not be so pure from the critic's point of view, but it was a very useful article. With regard to the Standard Specification, he did not think it ought to be made much more severe. So far it had been very useful to the manufacturer, because it had been the means of his coming to an understanding with his customers as to their requirements; but he had had to modify his plant more or less in order to bring the whole of his product to that standard, and to make it more severe now would be rather a hardship. He did not agree with Mr. Blount that the manufacture of cement would necessarily for the future be localised in the large consuming centres. It took about 50 cwt. of material to make 1 ton of cement, and therefore cost of transport would prohibit works being put down in districts in which the raw materials were not to be found. As to the use of puzzuolana, he really thought the proportion to be added and the reasons for which it was to be used, should be very carefully stated. It would not do to introduce it for all classes of work. For sea work it might be specified, but the proportions should be accurately stated. He thought the theory of Clifford

* "Engineer," March 4th, 1887. The patent is No. 5442, May 3, 1886.

Richardson that cement clinker was a solid solution was quite obvious, but it did not explain anything serviceable to the manufacturer.

Mr. W. J. A. Butterfield said he recollected the introduction of the rotary kiln by Mr. Ransome, and he understood that one of the chief causes of failure then was the difficulty of getting a sufficiently good basic lining. The principal change, however, was that then it was fired by gaseous fuel; now it appeared to be always fired by coal dust, and he would be glad to hear if the author considered that this change in the mode of firing had been in a large measure responsible for the present success of the rotary kiln.

Dr. Stevens said, with regard to the specification for Portland cement, there was one standard he looked for in vain on the table, and that was the ratio of lime to silica *plus* alumina. In the pamphlet published by the Standard Specification Committee this ratio was given as a sort of footnote. He did not know why it was put as a footnote, because if it was intended to hold good it should have been put in the text, but there appeared to be some difference of opinion about it, and it might want revising. For that reason he should like to hear the author's opinion on the matter.

Mr. Rhodin said he happened to consult Mr. Blount with regard to making white Portland cement; they were bent on the idea of utilising the potash in felspar for agricultural purposes, but they found the difficulty of having about 70 per cent. of residue which they did not know what to do with. Then they thought of utilising it for making Portland cement which should be white. They tried it in Denmark and other places, and eventually came to Mr. Blount and he tried it and actually made cement of exactly the same properties as ordinary Portland cement with practically very little colour. Mr. Blount ascribed the green colour to the 0·02 per cent. of manganese which occurred in felspar. But it appeared to him that if it could be derived from any trace of oxide, even a small trace of iron in these alkalis would cause a remarkable discoloration. There was one point on which he differed from Mr. Blount, and that was that the decrease in the cost of producing power should have made such a difference to chemical manufacturers. He had known of a case where £40,000 or £50,000 was spent on new machinery, and a saving of from 17 to 15½ per cent. resulted; but if they calculated the interest on the money spent he believed it would be the other way about. Last year he saw a 60 h.p. rolling mill driven by one of the old engines made by Mr. Watt himself, and it was quite economical.

Mr. Clayton Beadle asked what was the best length of a rotary kiln, and whether any great increase in the length above those now in use was probable. The Edison kilns were made of cast iron instead of wrought iron or steel, and they very quickly cracked; one of them had to be supported by iron bands. The prevalent idea then seemed to be that kilns 50 ft. long were the best, although some manufacturers were building them about 72 ft. Now, they heard that Edison had them in operation at a length of 150 ft.

Mr. Blount, in reply, drew attention to an old machine for testing the strength of cement which had been lent by Messrs. Cubitt, which was an interesting forerunner of modern testing machines. He said he should prefer to answer the criticisms which had been made on the paper in writing, as he could not go into them at that late hour, and he would only refer to such points as he could dispose of very briefly. As to the length of the kilns he should say a maximum length of 120 ft. was not far out. The ratio of lime to acid oxides was based on Le Chatelier's equation, but the value 2·75 was written in instead of 3, because the consensus of opinion on the Standard Committee was rather against going the full length; he quite agreed that the figure might be revised, and possibly raised a little. With regard to Mr. Butterfield's remarks, it was quite true there was trouble, apart from the basic lining; the producer gas was a cause of difficulty, because with it regeneration was necessary, and regeneration with a cement kiln was not an easy matter on account of the dust, among other things. He thought the rotary kiln in the early days had no great prospect before it until some form of fuel equivalent to oil fuel, which had already proved a success, had been devised. This end was attained when powdered coal was used. With regard to sulphur in the fuel, he did not know why it should be that sulphates should have a greater influence in one case than in another, but he admitted that there were many peculiarities in their action, and that sometimes an advantage was gained by using a mixture. With regard to the silica in the clinker, he thought that Mr. Bamber put the explanation correctly, but perhaps it was clearer to say that it was the surplus lime which made the cement unsound. He should like to join issue with Mr. Reid about the practice in 1886; he had no doubt the works with which Mr. Reid was acquainted pursued a practice better than he (Mr. Blount) had represented, but at the same time the methods which he had described were typical of what prevailed at that time. The engineer to whom he had referred was one of the largest users of cement, and had constructed most important works.

Mr. Blount, replying in writing to the rest of the discussion, agreed that all reasonable suggestions would be most carefully and impartially considered by the Standards Committee. He was much interested in Mr. Spoor's account of a vertical kiln using as little as 14 per cent. of fuel, and should like further details, as this consumption was within sight of the calculated minimum. It was true that there had been much debate concerning the permissible limit for magnesia, and that some magnesian cements behaved well; in view, however, of the want of precision of our knowledge of the chemistry of magnesian cements, caution was obligatory, at least on those responsible for a standard specification. With regard to trass, he did not think there could be two opinions as to its beneficial effect on the strength of concrete; where, when, and by whom it should be mixed, was another matter; on the whole the balance of advantage was with the plan of carrying out the mixture at the place where the cement was being used under the supervision of the engineer.

Mr. Bamber had unintentionally over-emphasised his (Mr. Blount's) views regarding the obsolescence of the use of wet raw materials. He believed that from the technical standpoint it was desirable that the wet process should be abandoned because of the necessity of driving off a large quantity of water, superfluous for any other purpose than aiding admixture. There was really no difficulty in mixing dry raw materials thoroughly; every-day experience was sufficient proof of this. He had touched on the sulphate question in his oral reply. He thought the difficulty of making sound cement from a sandy raw material arose from the fact that many of the particles were not sufficiently fine even after careful grinding to be in such intimate contact with the lime as to ensure their uniform union; thus silicates lower in lime, mixed with lime uncombined with silica, would exist side by side in the cement, the whole of the clinker would be soluble in acids, and nevertheless, because of its unsaturated lime, it would be unsound. Prof. Donnan's apparatus was, as he understood it, designed to measure the dilatation of the test piece as a block, and not to take account of pores or fissures; if that was the correct view, the best measurement was obtained when the mercury did not find its way into the interior of the block.

In reply to Mr. Gilbert, he wished to remark that the diagram given of a modern cement works was chosen as an instance of contemporary practice; every works had its different conditions to be met, and no doubt in some, even cheaper and simpler methods of handling would be possible; the sketch was typical and illustrative, and was not intended as a rigid standard which could not be departed from, whatever the situation and facilities of the works. He agreed that as at present the rotatory process was relatively young, and was being continually applied to raw materials, and in situations that were not quite identical with the materials and places where it had already been used, there was need for each case to be studied on its merits, and the plant modified accordingly.

He would add to what he had already said to

Mr. Reid, that he felt it was not that his description failed to give a true picture of the condition of things in 1886, but that Mr. Reid at that date was a little ahead of his time. The experiments on fused clinker referred to were of much later date than 1869, and proved clearly that fused cement, if of proper composition, was sound and strong. The fused cement which would not set and had to be thrown away was either of the same composition as ordinary clinker, or more probably was even lower in lime; in consequence, when fused, it was little better than a slag, and generally inert. He thought that so far from a blast-furnace process failing to produce a homogeneous cement, it was an apparatus eminently fitted to turn out a product of unfailing uniformity. He was glad to know that Mr. Reid regarded the replacement of ordinary lime by cement as desirable, and not improbable.

He thanked Mr. Friswell for his reference to the good work in early days of Mr. Frederick Ransome; he had himself touched on it some years ago in a paper presented to another institution. In his opinion the substitution of coal dust for gaseous firing had had a most important influence on the development of the rotary kiln.

Mr. Rhodin's remarks were of particular interest as showing how a waste product which was rather an incumbrance might be the raw material of a new industry; white Portland cement would serve many constructional and decorative uses, and its manufacture might well be undertaken. He could hardly believe that Mr. Rhodin, whom he knew to be eminently modern in his ideas, was serious in his contention that it was impolitic on the part of chemical manufacturers to adopt modern power plant. Of course, if the cost of the power was a small part of the whole cost of manufacture, it might not be worth while to replace old engines, but when, as in the case of the cement industry, the cost of power was an important item in the cost of manufacture, the manufacturer simply could not afford to go on using the heat engines of a past generation.

Journal and Patent Literature.

I.—PLANT, APPARATUS, AND MACHINERY.

(*Continued from page* 973.)

English Patent.

Distilling and evaporating liquids in vacuo; Method of and apparatus for ——. O. Unglaub, Salford. Eng. Pat. 18,172, Sept. 8, 1905.

The liquid to be evaporated, or distilled, is first run through a coil arranged within a jacket surrounding a vacuum chamber, and heated by steam traversing the jacket. The bottom end of the coil discharges into the vacuum chamber, wherein the lighter portions of the liquid are vaporised, and the heavier portions are discharged into a receiving chamber. (Reference is directed to Eng. Pats. 17,053 of 1896; 19,262 and 19,957 of 1898; and 6972 of 1902; this J., 1897, 601; 1902, 765.)—C. S.

United States Patents.

Vacuum pan. J. Kostálek, Prague, Austria-Hungary. U.S. Pat. 832,677, Oct. 9, 1906.

The vacuum pan has a "non-scorching" heating system movably mounted within; this consists of a series of superposed heating coils separated by inlet and outlet compartments, and so arranged that the outlet of one coil is connected to the inlet of the next. Valves are placed between the coils, so that the heating can be controlled, and the coils are provided with valved outlets for the escape of condensed liquid.—W. H. C.

[Separating] machine; Centrifugal ——. A. J. Ericsson, Assignor to Aktiebolaget Separator, Stockholm. U.S. Pats. 832,047 and 832,048, Oct. 2, 1906.

See Eng. Pats. 10,862 and 19,109 of 1905; this J., 1905, 958, and 1906, 418.—T. F. B.

Separator bowls; Distributing device for centrifugal ——. N. S. Bök, Stockholm. U.S. Pat. 832,837, Oct. 9, 1906.

See Fr. Pat. 355,062 of 1905; this J., 1905, 1162.—T. F. B.

Filter; Parallel ——. J. Kostálek, Prague, Austria-Hungary. U.S. Pat. 832,678, Oct. 9, 1906.

The claim is for a receptacle for the filtering medium, provided with inlet and outlet pockets arranged alternately, and connected to separate gutters. The pockets comprise a lower, unperforated collecting tube, an upper, perforated inlet tube, and a perforated collecting chamber, connecting and communicating with the tubes. —W. H. C.

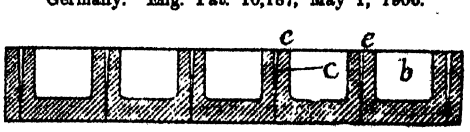
Drying apparatus. W. J. McElroy, Assignor to W. W. McElroy, Buffalo, N.Y. U.S. Pat. 832,874, Oct. 9, 1906.

An upright cylindrical casing is divided into chambers by horizontal partitions which have openings alternately at the centre and at the sides, through which the material passes from chamber to chamber. A vertical shaft, driven from above, passes through the centre of the casing, and is provided with an adjustable rotary horizontal shaft in each chamber, supported at its outer end by a wheel which runs in a track situated round the periphery of each chamber. A screw-conveying worm, supported and driven from the horizontal shaft, moves the material towards, and away from, the centre of alternate chambers.—W. H. C.

German Patent.

Steaming and drying apparatus; Movable perforated shelf in ——. H. Meyer. Ger. Pat. 172,451, May 3, 1905.

The patent relates to an apparatus which can be used both as a steaming or extracting apparatus, and as a dryer. When used for the first-mentioned purpose, the material under treatment rests on a perforated shelf in the rotating drum of the apparatus, but when used as a dryer, the shelf, by means of a suitable arrangement of levers, is made to hang loosely from one end, so that as the drum rotates, the material can come in contact with the whole of the heating surface.—A. S.



II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 976.)

Sugar cane; Composition and percentage of woody fibre in ——. *Value of bagasse as fuel.* H. Pellet. XVI., page 1059.

English Patents.

Filter-presses [for peat, &c.]. J. Hemmerling, Dresden, Germany. Eng. Pat. 10,187, May 1, 1906.

To avoid the contamination of the expressed liquid by fine particles of solid matter, a hollow chamber, a cross-

section of which is shown in the figure, is placed between each layer of material and the ordinary perforated separating plate. The liquid accumulates in the spaces, *b*, which are made sufficiently large to contain the whole of the liquid expressed from each layer of material, the fine particles of solid matter being kept back by the air pressure in the chambers. The latter are connected by shallow cross channels at *c*, which are provided with fine passages, *c*, through which the air, but not the liquid, can escape.—W. H. C.

Burners or furnaces; Hydrocarbon-fuel-. A. J. Boult, London. From Soc. in Partecipaz. per la Combustione Liquida, Genoa. Eng. Pat. 9121, April 17, 1906.

A HOLLOW metal casing is provided with a compressed-air inlet, and also with two inclined planes (one forming the hearth) down which the liquid fuel flows, these planes being perforated with slots or holes, in such wise that the compressed air escapes through them in different directions, but substantially, at right angles to each other, *i.e.*, the perforations in the one inclined plane are horizontal, whilst those in the other are vertical. A series of refractory bricks may be arranged in a suitable position above the burner, to ensure complete combustion, and, by reflecting heat on to the descending oil fuel, accelerate the vaporisation of the same.—C. S.

Coke ovens. W. Hiby, London. Eng. Pat. 27,001, Dec. 27, 1905.

IN order to protect the workmen from the smoke which is given off during the introduction of the fresh charge, the connection to the hydraulic main being shut off, a pipe is temporarily connected to the soot door of the ascension pipe. This pipe, which projects vertically upwards, has a steam jet so that it acts as an ejector which draws off the gases and smoke, and delivers them at a point well away from the door of the oven. The pipe is slung from a traveller which works on a gantry extending the whole length of the battery of ovens, so that it can be moved from oven to oven as required.—W. H. C.

Power Gas; Generation of ——. H. G. Boyd and W. R. McKay, London. Eng. Pat. 18,930, Sept. 19, 1905.

A MIXTURE of oyster, mussel, or other marine shells (9 parts), with iron, copper, or other metallic filings (say, 1 part), is placed in a vessel fitted with a rotary shaft and stirring blades. Dilute sulphuric acid is fed into the mixture according to requirements, and the gas generated is led off through a moisture trap, and storage vessel, to the motor to be worked by it.—H. B.

Gas generator furnaces. L. Bemelmans, Brussels. Eng. Pat. 19,617, Sept. 28, 1905.

THE generator has a rotary central shaft, and stationary outer wall, the shaft carrying devices which continuously raise the fuel, both at the sides and in the centre, in vertical slices, and let it drop, so as to prevent clinkering, &c. To agitate the main body of fuel in this way, arms carried by the rotary shaft, and provided with scrapers, extend over the stepped grate at a small distance above it, the arms being of such shape that the upper face forms an incline in the direction of rotation; as each arm moves, the fuel is raised by the inclined surface, and then suddenly drops behind the arm. In the centre of the furnace, where rotating arms have but little effect, a cylindrical body, forming a worm or screw-shaped incline, is provided upon the shaft; this likewise raises the fuel gradually, and then allows it to drop abruptly. The rising and falling movements affect the fuel throughout its entire height.—H. B.

Gas producer furnace; Processes of regulating the temperature of combustion in a —— for heating retort ovens or for other uses. H. L. Doherty, Madison, U.S.A. Eng. Pat. 19,716, Sept. 29, 1905. Under Int. Conv., Oct. 25, 1904.

See U.S. Pat. 829,105 of 1906; this J., 1906, 877.—T. F. B.

Gas producers. J. J. Bowmer, Newcastle-on-Tyne. Eng. Pat. 21,406, Oct. 21, 1905.

FOR the purpose of facilitating the removal of clinker from the grate of the producer, the bars of the grate are unconnected at one end, and are free from bearers or other obstructions below, so that an L-shaped pricker, inserted through the bars from below, may be drawn forward the full length of the bars, thus pulling out the clinker. A box-like device, which is open below and the inner side of which reaches down to near the fire-bars, is fixed over their front end; this maintains a clear space at the end of the bars, down through which the extracted clinker may fall into the ash-pit, whilst the inner side of the box holds back the main body of fuel, preventing it from falling forward over the front ends of the fire-bars. —H. B.

Carbonising coals for the production of illuminating and heating gases, and apparatus therefor. W. Young, Peebles, and S. Glover, St. Helens. Eng. Pat. 23,650, Nov. 17, 1905.

THE coal is carbonised in vertical or highly inclined retorts, which are heated externally by means of generator gases so that the coal becomes progressively hotter as it descends. The upper section of each retort, which is above the top level of the coal, and through which the coal-gas has to pass, is heated to a temperature lower than that of the sections below, whereby the gas is subjected to the action of radiant heat sufficient to "crack" the more complex vapours efficiently. The gas, on its way from the top of the retort to the hydraulic main, is led through the charge of raw coal contained in a closed section of the hopper surmounting the retort, whereby tarry and sooty matters are filtered off.—H. B.

Petrol and other oils; Process and apparatus for the vaporisation of —— for the production of carburetted air. W. P. Thompson, London. From Soc. d'Eclair. et de Chauff. par les Procédés A. Guy, Neuilly, France. Eng. Pat. 3892, Feb. 16, 1906.

IN the process of carburetting air, wherein the petrol or heavier hydrocarbon is fed, according to requirements, on to the surface of a body of water within the carburetting chamber, the evaporation of the hydrocarbon is quickened by heating the water by means of an external source of heat, as, for example, an ordinary hot-water circulating device.—H. B.

Gas [Carburetted air] for illuminating and heating purposes from petroleum spirit or other volatile oil or spirit; Apparatus for producing ——. B. K. Green and C. A. Horn, Great Malvern. Eng. Pat. 5222, March 3, 1906.

THE apparatus consists of a carburetting chamber, into which a part of the air supply is blown through pipes immersed in the hydrocarbon, so as to produce a spray, whilst the other portion of the air-supply is projected into the spray; a series of vertical pipes, leading the gas upwards to a drying and condensing chamber, which is charged with calcium chloride or bath-stone; and a back-flash safety valve fixed in the outlet from the condenser to the gas mains. In order that the gas production may vary automatically with the consumption, an air-escape valve, controlled by the internal pressure of the apparatus, is provided on the air-supply pipe of the carburetter: if, owing to fall in the gas consumption, the pressure rises, the relief valve opens more or less and allows more or less of the air to escape into the atmosphere. —H. B.

Carburetted air; Apparatus for the production of ——. Economic Safety Gas Co., Ltd., and C. C. Fowler, London. Eng. Pat. 12,076, May 23, 1906.

THE apparatus comprises a hot-air motor, the burner of which is fed with gas from the apparatus; a blower, driven by the motor, and forcing air through a pipe which is situated near the motor flame so as to be heated; a carburetter, through which the warmed air passes; and a gas-holder. The carburetter consists of a horizontal casing, divided by a partition into two compartments. From the smaller chamber, which is in communication with the petrol and warm-air supplies, three perforated pipes extend into the larger compartment, along the bottom, and the air forces petrol through these pipes, so that it issues upwards as a spray into the larger com-

compartment. The warm air flows from the small into the large compartment through several nozzles which pass through the partition, and mixes with the petrol spray before entering the gas-holder.—H. B.

Gases; Processes and apparatus for purifying ——, *and otherwise treating gases with liquids.* A. Elsenhans, Essen-Rüttenscheid, Germany. Eng. Pat. 25,665, Dec. 6, 1905. Under Int. Conv., Dec. 13, 1904.

See Fr. Pat. 360,341 of 1905; this J., 1906, 466.—T. F. B.

Explosive and other gases; Apparatus for detecting ——. H. E. Hauger and C. P. Pescheux, trading as Soc. H. Hauger and Pescheux, Paris. Eng. Pat. 3371, Feb. 12, 1906. Under Int. Conv., Feb. 22, 1905.

The apparatus consists essentially of a sensitive balance enclosed in a case open to the surrounding air by means of gratings; one arm of this balance carries a hermetically closed receptacle containing air at the usual temperature and pressure, the other arm carries a stirrup-shaped tray (bell-jar) of the same surface as the closed receptacle. The object of balancing in this way is to cause dust to settle equally on the receptacle and its counterpoise. The balance is adjusted so as to be in equilibrium in ordinary air; when, through the presence of foreign gases in the outer air, one side becomes heavier than the other and the balance inclines either way, pointers on the arms slip into mercury cups and close an electric circuit, thereby ringing an electric bell. Difference in temperature of the enclosed and outer air are equalised by a compensator fixed to the end of the arm which carries the counterpoise. This compensator consists of a spiral of soft iron and zinc soldered together, with the zinc on the outside. Expansion or contraction of the spiral through differences in temperature, causes a reel to slide horizontally on a wire attached to the beam in such a way that equilibrium is maintained. (Compare Eng. Pats. 15,694 of 1884; 7846 of 1891; and 11,703 of 1895; this J., 1885, 746.)—A. G. L.

Glow lamps; Process of manufacturing light-emitting bodies for electric ——, *and of connecting them with the supply conductors.* H. Kuzel, Baden, Austria. Eng. Pat. 5129, March 2, 1906.

See Fr. Pat. 366,267 of 1906; following these.—T. F. B.

United States Patents.

Combustible gas from carbonaceous liquids; Process and apparatus for generating a ——. F. Cotton, Hornsby, N.S.W. U.S. Pat. 831,835, Sept. 25, 1906.

See Eng. Pat. 18,291 of 1904; this J., 1904, 1021.—T.F.B.

Solvent and combustible for internal combustion engines; Liquid suitable as —— *and process of making the same.* W. Oppenheimer, Ewell. U.S. Pat. 832,409, Oct. 2, 1906.

See Eng. Pat. 4271 of 1904; this J., 1905, 722.—T. F. B.

Combustibles; Process for determining the heating power of ——. H. Junkers, Aix-la-Chapelle, Germany. U.S. Pat. 832,611. Oct. 9, 1906.

See Eng. Pat. 18,847 of 1904; this J., 1904, 1116.—T.F.B.

Coking apparatus. W. Kennedy, Pittsburg, Pa. U.S. Pat. 831,163, Sept. 18, 1906.

The plant claimed, comprises coking beds on which movable ovens are mounted, the gas-exit pipes of which communicate with a gas-exit flue beneath the coking-bed, when the ovens are in position. When the coking process is complete, the ovens are lifted by means of a kind of travelling crane, moved over a car, and the mass of coke discharged into the latter. Means are provided on the crane for operating a charging-hopper for delivering coal to the ovens.—A. S.

Gas; Apparatus for making ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 833,070, Oct. 9, 1906.

The gas-making apparatus consists of an L-shaped chamber, the upright limb being filled with refractory material, and the horizontal limb forming a coking and combustion chamber. The gases are withdrawn through an outlet some distance up the vertical limb of the chamber, and means are provided for introducing atomised oil into the combustion chamber. Oil and steam are admitted into the chamber at a point on the side of the outlet and opposite to the coking and combustion chamber. Coke is thus burned at one end of the casing, and the products of combustion pass in one direction entirely through the casing, whereby the refractory material next to the point of combustion is more highly heated than the rest of the material; also means are provided for excluding air, and for passing oil and steam through a portion of the refractory material nearest the point of combustion in one direction, and for simultaneously passing oil and steam in the other direction through a portion of the refractory material on the other side of the outlet.—W. C. H.

Gas Producer. A. M. Gow, Edgewood Park, Pa. U.S. Pat. 831,854, Sept. 25, 1906.

The producer consists of an upper (down-draught) chamber and a narrower lower (up-draught) chamber, the two being arranged out of vertical alignment and connected by means of a lateral passage, through which fuel may be discharged from the upper to the lower chamber. A gas off-take is situated adjacent to this passage, in the gasification chamber formed at the top of the lower chamber. Means are provided for feeding fuel to the upper chamber, and for controlling, independently, the supply of air and steam to the upper and lower chambers.—C. S.

Gases; Apparatus for manufacturing and mixing ——. B. Loomis, Hartford, Conn., and H. Pettibone, New Rochelle, N.Y., Assignors to Loomis-Pettibone Gas Machinery Co. U.S. Pat. 833,137, Oct. 9, 1906.

See Eng. Pat. 5911 of 1904; this J., 1904, 929.—T. F. B.

Gas purifying materials; Apparatus for treating ——. J. J. M. Bécigneul, Nantes, France. U.S. Pat. 813,114, Oct. 9, 1906.

See Addition of April 26, 1905, to Fr. Pat. 345,071 of 1904; this J., 1905, 1067.—T. F. B.

French Patents.

Coal; New artificial —— *composed of a mixture of beet-pulp and powdered coal, wood-charcoal, or coke, and an agglomerant.* J. P. Reneaux. Fr. Pat. 366,141, April 28, 1906.

The residual pulp from beet sugar works is ground (after drying if desired), and is then mixed with about 30 per cent. of powdered coal, wood-charcoal, or coke, the whole being rendered coherent by an admixture of about 10 per cent. of pitch, or other suitable adjunct, and pressed into any desired shape.—C. S.

Fuel; Production of —— *by treatment of "vinasse" or the liquid residues of alcohol distillation.* J. T. Connell, F. F. Haldane, and J. Thomson. Fr. Pat. 366,658, May 29, 1906. Under Int. Conv., July 6, 1905.

See Eng. Pat. 13,914 of 1905; this J., 1906, 604.—T. F. B.

Carburetted air; Apparatus for producing ——. Economic Safety Gas Co. Fr. Pat. 366,647, May 28, 1906.

See Eng. Pat. 12,076 of 1906; preceding these.—T.F.B.

Hydrogen gas; Installation for the production of ——. A. Thoms. Fr. Pat. 366,658, May 29, 1906.

A centrifugal pump, which takes gas from a hydrogen-generator and delivers it into a gas-holder, is driven by means of a gas motor, the gas-supply cock of which is so connected to the bell of the gas-holder that the gas is practically shut off when the bell is full, and is turned on as the bell descends. The cock which admits the gas from the pump into the gas-holder is similarly controlled by the movements of the bell. A cord, carrying a weight at one end, and attached to a tripping bar at the other, passes over a pulley on the shaft of the gas motor, and serves to give the latter the initial impulse required on restarting

[illegible] being at rest the [illegible] is connected to the [illegible] and [illegible] while the [illegible] is [illegible] with the [illegible] of the [illegible] gives the initial lift to the valve. The consecutive [illegible] may be sub-driven, instead of motor-driven, in which case the slip-on gear of the driving belt is controlled by the rise and fall of the gas-holder.—L. B.

Condenser for the separation of tar in gas-works. Cie pour l'Eclair. des Villes et la Fabr. des Compteurs et Appareils Divers. Fr. Pat. 366,447, May 21, 1906.

A HORIZONTALLY-ARRANGED casing, the bottom of which is inclined towards an opening at one end, from which the condensed tar flows into an ordinary tar-pot, is provided internally with a series of vertical partitions. The holes in one plate are not opposite to those in the adjacent plates; hence the gas is obliged to pursue a tortuous course in passing through the apparatus, and the tar is retained by impact against the surfaces of the plates. The sum of the areas of the perforations in each partition is equal to the cross-sectional area of the inlet or outlet pipe.—H. B.

Electrodes and filaments of pure graphite for electric lamps. M. Cresta. Fr. Pat. 366,142, May 12, 1906.

GRAPHITE, from which all impurities have been removed, is mixed into a paste with collodion and a small quantity of petroleum. The paste is formed into pencils or filaments, and the solvents are then driven off.—H. B.

Incandescence electric lamps; Process of making conductive connections, of metallic character, between the filaments and current leads of ——. H. Kuzel. Fr. Pat. 366,267, May 16, 1906. Under Int. Conv., Aug. 4, 1905.

FOR making the joints between the filaments (especially carbon filaments) and metallic leads of incandescence lamps, there are employed, as solder, the carbides of refractory metals, such as manganese, tungsten, thorium, &c., the carbides being either pure, or containing excess of carbon, or in solid solution in excess of the metal. For example, the ends of a carbon filament and of a nickel-wire lead are dipped into fused tungsten carbide, and the two ends are then united; or the carbide, finely powdered, may be mixed with an agglutinant, such as gum arabic, and then applied to the ends to be joined, the joint being next dried, and finally raised to a white heat in a suitable atmosphere. The carbide may also be formed in the process of soldering; for example, a mixture of 90 parts of powdered vanadium, 5 parts of graphite, 5 parts of gum arabic, and a little water, may be applied to the joint; on heating, vanadium carbide is produced.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 978.)

Crude petroleum; Determination of water in ——. E. Graefe. Petroleum, 1906, 1, 813—817.

ACCORDING to the author, the methods proposed by Wieleszynski (this J., 1904, 504) and by Nettel (this J., 1904, 952) for the determination of water in crude petroleum do not give concordant results. The method of inferring the proportion of the water by the difference of specific gravities of the crude oil and of the dehydrated oil is shown to be inaccurate. The author proposes a process based on the decomposition of the water by metallic sodium, and collection of the hydrogen evolved. From 5 to 10 c.c. of ether free from water and alcohol are placed in a small distilling flask of 30—40 c.c. capacity, a small quantity of finely-divided metallic sodium is introduced quickly through a funnel with a wide stem, and the latter washed with a further 5 c.c. of ether. A cork carrying a small separating-funnel, the stem of which is drawn out to a point, is now fixed in the neck of the flask, so that the stem dips below the surface of the ether. The delivery tube of the distilling flask [illegible] mercury [illegible] burette, [illegible] bursting of the [illegible] shaken, is now introduced into the separating-funnel well mixed therein with 1 c.c. of ether, the mixture run into the distilling flask, and the funnel washed with further 1 c.c. of ether. From the volume of hydrogen obtained, 2 c.c. are deducted to allow for the [illegible] by the petroleum and other introduced [illegible]. From the number of c.c. of hydrogen the [illegible] in mgrms. can be calculated by means of the [illegible]

$$\frac{a \times 0{\cdot}679 \times b}{273+t}$$

where a represents the volume of hydrogen in c.c., [illegible] barometric pressure, and t, the temperature.—A. S.

ENGLISH PATENT.

Sewage sludge and other waste matters of an organic origin; Destructive distillation of ——, *for the recovery of by-products such as ammonia and oil therefrom, and the utilisation of the residue.* J. C. Buttenshaw, London, and G. Watson, Leeds. Eng. Pat. 19,538, Sept. 27, 1905.

THE precipitated sludge, from which the greater part of the water has been removed by pressing or other means, is introduced into a retort, and subjected to the action of heat and steam. The organic matter is decomposed into gaseous and oily products, which are recovered in the usual manner, whilst the residue is converted into ammonia. The retort is surrounded by flues fitted with dampers, so arranged as to permit of the formation of zones of different temperature, some of which may be so far heated that the carbonaceous residue may be burned by the oxygen resulting from the decomposition of the steam, the retort being heated by the waste gases given off by the material, or by previously treated and heated air with or without the addition of producer or other gas. The retort is preferably vertical, and is fed from the top. Provision is made for the continuous removal of the spent material through the bottom, which material may be employed after suitable treatment as precipitant for fresh sewage.—D. B.

UNITED STATES PATENTS.

Retort [for wood distillation]. P. Jackson, Assignor to J. S. Schofield's Sons Co., Macon, Ga. U.S. Pat. 832,976, Oct. 9, 1906.

A CLOSED cylindrical vessel with a removable cover at one end is mounted by hollow trunnions on a support so that it can be inclined at any angle. Two parallel perforated pipes, connected by a cross pipe at the centre, extend the whole length of the vessel parallel with and close to the interior surface, so that when the vessel is in the horizontal or working position they lie parallel with the bottom. The cross piece is connected by a pipe with one of the hollow trunnions through which steam can be introduced into the perforated pipes. The products of distillation escape through an opening opposite the steam inlet, which is connected to the other hollow trunnion.—W. H. C.

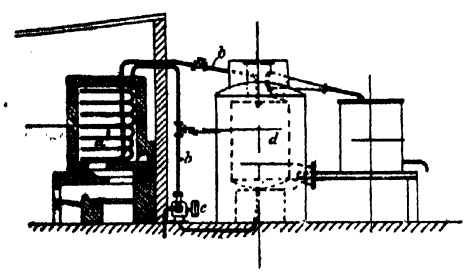
Hydrocarbon oils; Refining and purifying ——. D. T. Day, Washington, D.C. U.S. Pat. 826,089, July 17, 1906.

THE distilled oil is filtered through a porous absorbent material such as palladium black or platinum sponge, charged with hydrogen or absorbable hydrogen-carrying (hydrocarbon) gas or vapour, a supply of such gas or vapour being kept in contact with the absorbent material during the filtering process.—C. S.

"Mastic"; Art of producing ——. H. Paschke, New York. U.S. Pat. 832,697, Oct. 9, 1906.

THE method of producing "mastic" described consists in granulating a cold, soluble, waterproof (bituminous) substance, and subjecting it to the action of a volatile solvent, whereby the evaporation of the solvent is delayed sufficiently to enable it to attack the outer surfaces of the

grains of granulated waterproof material, and soften them so that they adhere to form a stiff plastic mass. Such a mass may be laid in any desired form or position before the action of the solvent extends to the interior of the grains of granulated waterproof material.—W. C. H.



FRENCH PATENT.

Mineral oils furnishing a stable emulsion, and mineral-oil soaps that dissolve to a clear solution; Method of preparing ——. E. Junginger. Fr. Pat. 366,293, March 29, 1906. Under Int. Conv., June 20, 1905.

AN alkali compound of a sulphonated oil (Turkey red oil) is treated with a salt of magnesia or other soluble metallic salt that will furnish a soluble product, and the resulting compound is mixed with an equal quantity of oleic acid and sufficient ammonia (sp. gr. about 0·910) to impart an alkaline reaction and clarify the mixture, whereupon the whole is incorporated with mineral oil and allowed to cool. To produce a fairly clear and stable soap, this product is dissolved in hot water along with about 3 per cent. of calcined potassium or sodium carbonate (calculated on the weight of the oil). This can be concentrated by heat to the consistence of ordinary soft soap.—C. S.

GERMAN PATENTS.

Distilling apparatus for tar and other inflammable liquids and those liable to froth. De Clercq's Patent-Ges. zur Fabrikation der Teer- und Dachpappenmaschinen m. b. H. Ger. Pat. 166,723, Jan. 27, 1904.

THE feature of the type of apparatus, of which the accompanying diagram is an example, is that the tar or other liquid is caused to circulate, by means of the pump, *c*, from the jacketed still proper, *d*, through the coil, *a*, in which it is heated by the gases from the furnace below, and is then pumped back, through *b*, to the still. In this way, it is stated that high temperatures can be attained, without risk of frothing or fire.—T. F. B.

Tar oils for impregnating, preserving, and disinfecting purposes; Process for working up heavy ——. H. Nördlinger. Ger. Pat. 168,611, Jan. 21, 1905. Addition to Ger. Pat. 121,901, May 24, 1899.

THE antiseptic properties of heavy tar oils are said to be considerably increased by the addition of normal or acid (metallic) salts of fatty acids from propionic acid to caprylic acid, or of the corresponding acids of the acrylic acid series; these salts are more readily soluble in the tar oils than are acetates.—T. F. B.

Lubricants; Apparatus for testing ——. J. Walther. Ger. Pat. 171,181, May 29, 1904. XXIII., page 1068.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 978.)

Aromatic amines; New method for the preparation of ——. F. Sachs. Ber., 1906, **39**, 3006—3028.

THE author has investigated the action of sodamide on naphthalene and some of its derivatives, whereby primary amines have been obtained. These are formed in three ways, viz.:—(1) By substitution of the amino for the sulphonic acid group; (2) by replacement of hydrogen in the naphthols and naphthylamines; (3) by replacement of hydrogen in naphthalene itself in presence of substances capable of supplying oxygen. From the 1:5-, 1:8-, and 2:7-naphtholsulphonic acids the corresponding aminonaphthols were prepared in good yield. In the case of the 2:6- and 2:8-naphtholsulphonic acids the entering amino-group did not take the place of the eliminated sulphonic group, but 1:6-aminonaphthol was produced in each case. When β-naphthol (30 grms.) was heated with 1½ parts of sodamide in presence of naphthalene for one to two hours at 205°—220° C., hydrogen was evolved, and 1:6-amino-naphthol (15·5 grms.) obtained. α-Naphthol similarly yielded 1:5-aminonaphthol. Naphthionic acid gave 1:4-naphthylenediamine together with α-naphthylamine. Anthraquinone-β-sulphonic acid gave an aminoanthraquinone, m. pt. 256° C., which did not correspond to the two known aminoanthraquinones. The naphthylamines behaved similarly to the naphthols: thus from α- and β-naphthylamine, 1:5- and 1:6-naphthylenediamine respectively were obtained. Naphthalene itself, when treated with sodamide in presence of phenol, formed substitution products, and α-naphthylamine as well as 1:5-naphthylenediamine resulted.—J. C. C.

Phenylhydrazine; Reduction with ——. *New method for the preparation of the 5-amino-derivative of salicylic acid.* E. Puxeddu. Gaz. Chim. Ital., 1906, **36** [2], 87—89.

THE method described by Oddo and Puxeddu (this J., 1905, 1103) for the reduction of hydroxyazo compounds by means of phenylhydrazine can be used for the preparation of 5-aminosalicylic acid, which has recently become of importance in the dyestuff industry. The benzeneazo-derivative of salicylic acid, $(COOH)(OH)C_6H_3N:NC_6H_5$, (m. pt. 211° C.), was prepared by combining 14 grms. of salicylic acid dissolved in 45 c.c. of 20 per cent. sodium hydroxide solution, and diluted to 200 c.c., with the diazo solution obtained from 9 grms. of aniline, 30 c.c. of 40 per cent. hydrochloric acid, and 50 c.c. of 20 per cent. sodium nitrite solution. Five grms. of the azo compound were heated with excess of phenylhydrazine to 100° C., and the source of heat was then removed; the temperature rises to 185° C., and the reduction is complete in about 10 minutes. The pure aminosalicylic acid, $(COOH)(OH)C_6H_3.NH_2$, is obtained, with a quantitative yield, by washing the product with petroleum spirit. It forms a white crystalline mass, with no definite melting point, which becomes brown when exposed to the air. It is soluble in dilute alkalis and acids.—A. S.

1.4-Anthraquinone. C. Haslinger. Ber., 1906, **39**, 3537—3538.

DIENEL (this J., 1906, 309) gives the melting point of the above compound as 206° C. The author, however, states that at 190° C. blackening takes place, the substance undergoing decomposition. Its conversion into quinizarin has been further investigated, and the progress of the reaction followed quantitatively. From 2 grms. of the anthraquinone, 2·6 grms. of diacetyl-1.4-anthrahydroquinone were obtained. This crystallises from alcohol in almost colourless needles, melting at 169° C., and is converted into diacetylquinizarin when subjected to oxidation with chromic and glacial acetic acids, 2 grms. of the hydroquinone yielding 1·4 grms. of the diacetyl compound. For the production of quinizarin the latter is treated with sulphuric acid, 0·9 grm. of diacetyl derivative giving 0·6 grm. of quinizarin.—D. B.

Hydroxyanthraquinones; Methylation of ——. C. Graebe, C. Thode, and H. Bernhard. Annalen, 1906, **349**, 201—231.

HYDROXYANTHRAQUINONES containing the hydroxyl group in the 1-position either resist methylation wholly or are but imperfectly methylated. Better results are obtained when the corresponding desoxy-derivatives are subjected to methylation. From the resulting ethers the respective methoxyanthraquinones are thereupon obtained by oxidation. Desoxyalizarin dimethyl ether was prepared by treating desoxyalizarin with dimethyl sulphate in

alkaline solution. It crystallises in yellow needles melting at 150° C., and fails to yield an oxime or acetyl derivative. The diethyl ether melts at 128° C. By subjecting the dimethyl ether to oxidation with sodium chromate and glacial acetic acid, alizarin dimethyl ether (this J., 1905, 192) is obtained. Alizarin mono-methyl ether, like alizarin, can only be completely methylated when it is first reduced, then methylated, and eventually re-oxidised. Alizarin dimethyl ether is reduced by zinc dust and ammonia to desoxyalizarin dimethyl ether. The action of diethyl sulphate on alizarin in alkaline solution leads to the formation of a diethyl ether which crystallises in yellow needles melting at 162° C. Flavopurpurin dimethyl ether obtained by treating flavopurpurin in alkaline solution with dimethyl sulphate forms yellow needles, which melt at 239° C. It is also prepared by heating the trimethyl ether with sulphuric acid at 100° C. The latter was produced by methylating desoxyflavopurpurin, and oxidising the resulting ether with sodium chromate and glacial acetic acid. It crystallises from alcohol in needles which melt at 225°—226° C. When hydroxyanthrarufin is subjected to direct methylation, its monomethyl ether is formed. This melts at 202° C., and does not possess tinctorial properties. Reduction with zinc dust and dilute ammonia gives rise to the formation of 1.2.5-trihydroxyanthrone, the desoxy-derivative of hydroxyanthrarufin, which melts at 258° C. and gives on methylation a methyl ether melting at 140° C. Hydroxychrysazin trimethyl ether was prepared by reducing hydroxychrysazin with zinc dust and ammonia, methylating with dimethyl sulphate, and oxidising. It melts at 157° C. and is converted into the dimethyl ether when heated with sulphuric acid for 15—30 minutes at 100° C. The mono-methyl ether is produced by direct methylation, forming orange-yellow needles which melt at 220° C. 2-Methoxyanthraquinone was obtained by methylating 2-hydroxyanthraquinone, whilst the 1-methoxy-derivative was best prepared by heating the sodium salt of erythrohydroxyanthraquinone with potassium methyl sulphate at 200° C. The latter melts at 169·5° C. 2.7-Anthrapurpurin dimethyl ether, melting at 241° C., was produced by methylating anthrapurpurin or heating its trimethyl ether with sulphuric acid at 100° C. The latter was formed by treating desoxyanthrapurpurin with dimethyl sulphate in alkaline solution, and subjecting the resulting ether to oxidation. It crystallises in yellow needles melting at 201° C. The direct methylation of purpurin leads to the formation of an orange-red mono-methyl ether melting at 240° C., whilst the methylation of the reduction products of purpurin gives rise to the production of xanthopurpurin methyl ethers.—D. B.

Phenosafranines; Symmetrical and unsymmetrical —— [*Azine dyestuffs*]. *II.* P. Barbier and P. Sisley. Bull. Soc. Chim., 1906, **35**, 858—868.

When the two phenosafranines (see this J., 1905, 1296) are diazotised under similar conditions, the solution of the symmetrical isomeride rapidly changes to blue, whilst that containing the unsymmetrical base changes very slowly; this difference in rates of diazotisation may be utilised to separate a mixture of the two isomerides, if, after a few minutes, the diazotised solution is extracted with amyl alcohol; the greater portion of the *unsymm*-phenosafranine is extracted, most of the symmetrical isomeride having already been diazotised. Another method of separation consists in extracting the solution of mixed hydrochlorides with pure chloroform; no *symm*-phenosafranine is extracted, but the major part of the unsymmetrical compound is removed; it is stated that 5 per cent. of "azophenosafranine" can be detected in this way. The authors conclude by describing the preparation of the pure anhydrous hydrochlorides, the hydrochlorides containing 1·5 and 5 mols. of water of crystallisation, the sulphates, nitrates, and oxalates; also the hydrochloride of unsymmetrical phenosafranine containing 3 mols. of water, and that of symmetrical phenosafranine containing 4 mols. of water of crystallisation.—T. F. B.

Azomethine compounds; Influence of the carbon double bond on the colour of ——. R. Möhlau and R. Adam. Z. Farben-Ind., 1906, **5**, 377—383.

The authors have investigated the azomethine compounds from the point of view that an increase in the number of chromophores in the molecule leads to an increase in the depth of colour. For this purpose the group—C:C—C:N— was chosen. Compounds possessing this group were obtained by condensing cinnamic aldehydes with primary amines containing an auxochrome group. To determine the influence of the group—C:C—the simple azomethine compounds were compared with the foregoing. The following substances were examined with regard to the increase in colour by the introduction of chromophore and auxochrome groups, and the change of shade due to their position: the condensation products of (1) *p*-aminodimethylaniline, (2) *p*-aminophenol, (3) *o*-aminophenol, (4) 1-amino-4-naphthol, (5) 1-amino-2-naphthol, (6) 1:2:5-aminosalicylic acid with benzaldehyde, the three nitrobenzaldehydes, and *p*-dimethylamino-benzaldehyde on the one hand, and with cinnamic aldehyde, the three nitrocinnamic aldehydes, and *p*-dimethylaminocinnamic aldehyde on the other hand. Thus cinnamylidene-*p*-aminodimethylaniline is yellow, whilst the three isomeric nitro-compounds are orange to dark red; *p*-nitrocinnamylideneaniline is yellow, and *p*-nitrocinnamylidene-*p*-aminodimethylaniline is dark red. The above-mentioned substances do not all react in the same manner; thus, under normal conditions *o*- and *p*-aminophenol form addition products with the three nitrobenzaldehydes, and judging from a number of other similar cases occurring in literature, it would appear that the presence of acid groups prevents the elimination of water in these reactions. A large number of examples from literature bearing on the subject are cited, and further results will be published later.—J. C. C.

Synthetic organic dyestuffs; Action of liquid sulphur dioxide on certain ——. E. Grandmougin. Z. Farben-Ind., 1906, **5**, 383—385.

Liquid sulphur dioxide behaves as a solvent towards organic dyestuffs; it does not act as a reducing agent or as an acid. Benzeneazo-*p*-naphthol and similar dyestuffs were crystallised from solution in the liquid sulphur dioxide, such solution being very similar in colour to those which are obtained with glacial acetic acid.—J. C. C.

English Patents.

Colouring matters [*Dyestuffs*]; *Manufacture of blue and black* [*Azo*] ——. Read Holliday and Sons, J. Turner, and H. Dean, Huddersfield. Eng. Pat. 22,513, Nov. 2, 1905.

By combining diazotised *p*-aminobenzeneazo-*a*-naphthylaminesulphonic acids (1:6 or 1:7) with 1 mol. of aminonaphtholmonosulphonic acid in alkaline solution, intermediate products are obtained, which, when further diazotised and combined with 1 mol. of *m*-phenylenediamine, *m*-toluylenediamine, or chloro-*m*-phenylenediamine (1:2:4), lead to the formation of blue to bluish-black dyestuffs, dyeing cotton directly and possessing great affinity.—D. B.

Colouring matters [*Dyestuffs*]; *Production of* ——. E. Vidal, Huddersfield. Eng. Pat. 23,740, Nov. 17, 1905.

Blue-black dyestuffs which dye cotton direct are produced by heating *p*-aminohydroxy-compounds with sulphur, and then adding caustic soda solution (40° B.) to the melt at below 100° C. The fluid mixture solidifies, and is dried. Example:—A mixture of *p*-aminophenol (100 kilos.) and sulphur (60 kilos.) is melted, and is then heated at 160°—200° C. until the whole is solid. The product is crushed, and mixed with 75 kilos. of caustic soda solution (40° B.). After solidification the mixture is dried below 100° C., and crushed.

A dyestuff producing a blacker shade may be obtained by adding sulphur (13 kilos.) or sodium sulphide (20 kilos.) or both to the melt before the final solidification takes place. The *p*-aminophenol may be replaced by the corresponding amino-ortho- and amino-meta-cresols, 1:2:4-diaminophenol, 1:4-aminonaphthol, or a mixture of two of these; the quantity of sulphur being increased in proportion to the increase of the molecular weight of the amino-compound.—J. C. C.

Dyestuff; Manufacture of a red —— [*Thioindigo Red*]. Kalle und Co. Akt.-Ges., Biebrich on Rhine, Germany. Eng. Pat. 17,162, July 30, 1906. Under Int. Conv., Nov. 13, 1905.

It has been found that the products described in Eng. Pats. 22,736 and 23,316 of 1905 (this J., 1906, 424 and 736) combine readily with isatin resulting in condensation products having the formula:

$$C_6H_4\!<\!\overset{S}{CO}\!>\!C\!:\!C\!<\!\overset{CO}{C_6H_4}\!>\!NH$$

and forming red dyestuffs, which are insoluble in water, but dissolve in alkaline reducing agents.—D. B.

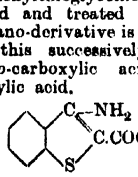
UNITED STATES PATENTS.

Dyestuff; Process of making a red vat-dyeing —— [*from salicylthioacetic acid*]. G. Engi, Assignor to Society of Chemical Industry in Basle, Switzerland. U.S. Pat. 831,844, Sept. 25, 1906.

SEE Eng. Pat. 4687 of 1906; this J., 1906, 470.—T. F. B.

Dyestuff; Black polyazo ——, *and process of making same.* A. L. Laska, Offenbach, Assignor to Chem. Fabr. Griesheim-Elektron, Frankfort-on-Maine, Germany. U.S. Pat. 832,393, Oct. 2, 1906.

SEE Eng. Pat. 6189 of 1906; this J., 1906, 750.—T. F. B.



FRENCH PATENTS.

Anthracene compounds; Production of new ——. Badische Anilin und Soda Fabrik. First Addition, dated May 7, 1906, to Fr. Pat. 357,239, Aug. 25, 1905. Under Int. Conv., April 12, 1906.

SEE Eng. Pat. 10,505 of 1906; this J., 1906, 751.—T. F. B.

Thionaphthene; Process for preparing derivatives of ——. Kalle und Co. Fr. Pat. 366,611, May 26, 1906. Under Int. Conv., March 9, 12, and 27, 1906.

CHLORACETIC acid is condensed with o-aminothiophenol, and the product further condensed to form an inner anhydride; this may be saponified by heating with dilute alkali, *o*-aminophenylthioglycollic acid being produced. This is diazotised and treated with cuprous cyanide, whereby the *o*-cyano-derivative is obtained. Saponifying agents convert this successively into the amide of phenylthioglycol-*o*-carboxylic acid, and *a*-aminothionaphthenecarboxylic acid.

Twenty per cent. sodium hydroxide solution may be used for the condensation. The carboxylic acid may be converted into *a*-aminothionaphthene by gently heating with dilute acids, and, by further heating, into *a*-hydroxythionaphthene (thioindoxyl).—T. F. B.

Phenylthioglycol-o-carboxylic acid; Process for preparing ——. Kalle und Co. Fr. Pat. 366,612, May 26, 1906. Under Int. Conv., March 9, 12, and 27, 1906.

A SOLUTION of diazotised anthranilic acid reacts with sodium polysulphides, at low temperatures, with evolution of nitrogen. When this has ceased, the original yellow solution will have become colourless, and acids will precipitate from it a thio-derivative of benzoic acid. If chloracetic acid or one of its salts be added to an alkaline solution of this compound, and the mixture heated to about 80° C. and filtered, phenylthioglycol-*o*-carboxylic acid may be precipitated by addition of acids.—T. F. B.

Thioindigo Red; Process for preparing the leuco-derivative of ——. Kalle und Co. Fr. Pat. 366,613, May 26, 1906.

THIOINDIGO Red (see Fr. Pat. 359,399 of 1905; this J., 1906, 424) may be reduced to a leuco-derivative of acid character by treatment with a reducing agent. If the reduction is effected in alkaline solution, the alkali salts of the leuco-compound are obtained, and the free base is precipitated from these by addition of acids; it is very slightly soluble in water, and only oxidises very slowly in air; it is so stable that it can be used in industry. Five kilos. of the dyestuff, in the form of a 30 per cent. paste, may be reduced by means of a solution containing 300 grms. of anhydrous sodium hyposulphite (hydrosulphite) and 2·5 litres of caustic soda solution, 40° B., heated gradually to 60°—70° C., until reduction is complete; the product is run into dilute acid, in absence of air, and the precipitate filtered and washed with water. Thioindigo Red may also be reduced in alkaline solution by thioindoxyl or thioindoxylcarboxylic acid (see Fr. Pat. 366,611, preceding this).—T. F. B.

Chloroacetanilides; Process of making ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 366,646, May 28, 1906.

YIELDS of *w*-chloroacetanilide or its homologues, amounting to 70 per cent. and upwards of the theoretical yield, are obtained by heating a suitable salt of aniline or one of its homologues with monochloracetic acid, in presence of a chloride of phosphorus or of sulphur. For example, 260 parts of aniline hydrochloride and 200 parts of monochloracetic acid are heated together to about 100° C., in a vessel provided with a stirring device and a vertical condenser; 100 parts of phosphorus trichloride are gradually added to the mixture, and the heating is carried to 140°—160° C. for a short time, and the product allowed to solidify, when it is introduced into water, and the chloroacetanilide filtered off and re-crystallised if desired.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 982.)

Textile fibres; Chemical functions of ——. L. Vignon. Compt. rend., 1906, **143**, 550—552.

THE author has continued his former researches (this J., 1890, 771 and 855) on the behaviour of wool, silk, and cotton when immersed in solutions of acids, bases, and neutral salts. Known weights, usually about 10 grms., of the scoured fabrics were allowed to remain for one hour at the ordinary temperature in aqueous solutions (1 : 100 and 1 : 1000) of these reagents, and thoroughly washed with distilled water after treatment. In the following table, K is the weight in grammes of the acid, base, or neutral salt in 100 grms. of the solution before contact with the fabric, K_1 the weight of the reagent in 100 grms. of the solution after treatment, K_2 the weight of substance fixed by 100 grms. of the fabric. $\frac{K_2}{K_1}$ is called the coefficient of division of the acid, base, or salt between the fabric and the water.

(1) *Action of acids.* Sulphuric acid:—

Fabric.	H_2SO_4 (1 : 100); 400 grms.				
	Weight of fabric.	K	K_1	K_2	$\frac{K_2}{K_1}$
Silk (raw)	10·0	1·015	0·959	2·169	2·26
Silk (ungummed) ...	8·53	1·015	0·985	1·279	1·40
Cotton	9·12	1·015	1·016	nil	nil
Wool	9·85	1·015	0·902	4·379	4·85

Fabric.	H_2SO_4 (1 : 1000); 400 grms.				
	Weight of fabric.	K	K_1	K_2	$\frac{K_2}{K_1}$
Silk (raw)	9·92	0·093	0·054	1·77	33·77
Silk (ungummed) ...	10·20	0·093	0·079	1·06	14·93
Cotton	9·13	0·093	0·095	nil	nil
Wool	9·70	0·093	0·035	3·90	111·5

(2) *Action of base.* Barium hydroxide:—

Fabric.	$Ba(OH)_2$ (1:100); 350 grms.				
	Weight of fabric.	K	K_1	K_2	$\frac{K_2}{K_1}$
Wool	10·16	1·103	0·853	4·916	5·76
Cotton	9·77	1·103	1·026	2·673	2·60

Fabric.	$Ba(OH)_2$ (1:1000); 350 grms.				
	Weight of fabric.	K	K_1	K_2	$\frac{K_2}{K_1}$
Wool	9·78	0·105	0·037	2·379	64·5
Cotton	9·53	0·105	0·094	0·388	4·127

To avoid carbonation of the baryta, the samples of fabric and the baryta solution were mechanically shaken for one hour in a closed glass vessel.

(3) *Action of neutral salts (sodium chloride).*—Similar experiments were made with cotton and wool using solutions of sodium chloride (1:100 and 1:1000), but no change in the concentration of the solution was observed. Check experiments were made with powdered wood-charcoal and the foregoing reagents, but the results were negative in each case, no absorption taking place. The following conclusions are drawn: (1) Textile fabrics should be regarded as active chemical molecules; (2) animal fibres possess acidic and basic properties; (3) vegetable fibres have no basic properties, but are faintly acidic in character, being comparable with the alcohols; (4) porous substances such as powdered wood-charcoal are chemically inert. The chemical activity, acidic or basic, of fabrics increases with the dilution of the solution. This is shown by the variations of $\frac{K_2}{K_1}$ and is connected with the ionisation of the solution employed. An explanation of the exhaustion of dye-liquors by textile fibres is thus provided.—J. C. C.

Chromate of lead; Suggestions for the amendment of the special rules for factories and workshops in which —— is used, or in which goods dyed with it undergo the processes of bundling and noddling, winding, reeling, weaving, or other treatment. Report to the Home Office by the Medical Inspector of Factories, Oct. 1, 1906.

Recent inspection of dye-works in which lead compounds are employed has shown that a serious percentage of the workers are more or less affected both by the lead and by the chromate solutions used in dyeing yarn with yellow and orange lead chromate. (See this J., 1905, 1282.) The chief danger from lead seems to occur in the operation of "heading" or manipulating the yarn over a bar or post. The existing Special Rules for dye-works in which lead chromate is used have given rise to considerable difficulties in administration, by reason of their very wide application, and amendment of them in certain respects is now desirable. It is therefore proposed that they should be replaced by new regulations, which should be limited to those factories where the danger of lead poisoning has been found to be serious, and a draft of the suggested regulations is submitted for consideration. Many of the clauses are identical with those contained in regulations for factories where lead compounds are used for the manufacture of paints (this J., 1906, 702), such as those for periodical inspection of the workers (every three months), for a record of the results in a Health Register, and for power of suspension from working with lead compounds; also for the provision and use of lavatory accommodation and overalls, suitable places for depositing food, clothing, &c., and of a separate meal room in cases where the factory is not closed during meal times. The employment of efficient exhaust draught is regarded as the most effectual means of ensuring safety, and although it is thought undesirable to specify too closely how the draught should be applied, the opinion is expressed that the air should have a linear velocity of 250 ft. per minute at a distance of 8 ins. behind or under the point where heading is done. The speed of the draught at the ordinary opening is to be determined at least once in every three months and recorded in the Health Register. To protect against the local ulcerating action of chromate solutions where any abrasion of the skin has occurred, adhesive plaster and any other requisites prescribed by the certifying surgeon are to be provided and kept in readiness for the use of persons employed. The Secretary of State invites observations on the suggested regulations.—M. J. S.

Red diazo ground, reserving a black dyestuff printed over it. L. Bloch and E. Zeidler. Bull. Soc. Ind. Mulhouse, 1906, 76, 229—230.

Starting from the fact that the diazo compound of paranitraniline withstands the action of chromic acid, Elbers, Frey, Kurz, and Grosheintz obtained a red discharge on indigo by mixing the diazo solution with alkali chromate, and afterwards passing the material through an acid bath. The authors add chromate to the usual red, which is printed on fabric which has been prepared with β-naphthol, and printed over with a dyestuff which can be developed on β-naphthol, and destroy the dyestuff afterwards by the chromic acid which is formed on taking the goods through an acid bath. Besides Dianisidine Blue and Benzidine Brown, used by the authors, all other dyestuffs known under the names of Diazo Black, Azophor Black, &c., can be used in the same way.—H. Bz.

α-Naphthylamine Claret; Discharge of ——, by means of formaldehyde-sulphoxylate. A. Schaunert and J. Frossard. Sealed communication, 1574, dated Oct. 18, 1905. Bull. Soc. Ind. Mulhouse, 1906, 76, 219—221.

The authors have succeeded in discharging α-Naphthylamine Claret with a neutral discharge, which at the same time completely discharges Paranitraniline Red, Chrysoïdine, &c. On heating formaldehyde-sulphoxylate with a thickening material and aniline, preparations are obtained which completely discharge α-Naphthylamine Claret. The formaldehyde-sulphoxylate is heated to about 60° C., the aniline or xylidine added, and the temperature raised to about 70° C.

In an additional note, dated June 27, 1906, to the preceding communication, it is stated that on working according to the process therein described bad results were frequently obtained with white discharges. It is now found that the discharging power is considerably increased by the addition of certain salts, as, for instance, carbonate, acetate, citrate, or oxalate of ammonium. In presence of xylidine these salts do not decompose formaldehyde-sulphoxylate. The addition of these salts is only required for white discharges and not for coloured ones. A few examples are given. After printing, the goods are taken once or twice through the Mather-Platt, then through a 10 per cent. bichromate solution, and soaped.

White discharge on α-Naphthylamine Claret.—*White T. W. I.:* Rongalite C., 300 grms.; tragacanth solution, 200 grms.; water, 125 grms., and xylidine, 175 grms., the whole being heated to 40° C. *White T. W. O.:* White T. W. I., 800 grms., ammonium oxalate, 50 grms., and tragacanth solution, 150 grms. (this white is the one which is printed on Naphthylamine Claret). *Yellow T. W.:* Thioflavine T., 50 grms.; water, 50 grms.; White T. W. I., 800 grms.; and tannin 50 per cent., 100 grms. *Blue T. W.:* Thiomine Blue, 50 grms.; water 50 grms.; White T. W. Dry cleaning. Home Office Memorandum 824, Oct., 1906. E. A. Whitelegge, Inspector of Factories.

To minimise the risk of ignition of the "benzine" by electric sparks generated by friction of the materials, the air should be kept moist, so that the relative humidity does not fall below about 70 per cent. of saturation. An addition of 0·1 per cent. of "antibenzinpyrin," or a soluble oleate, is also a preventive. The working appliances in which inflammable spirit is used should be kept closed by means of balanced covers that will fall back into place if disturbed by an explosion. For such as must be open while in use, easily lowered iron covers should be provided. Used spirit should be conveyed in closed pipes to the settler or still, situated in a special room. No naked lights should be used in benzine rooms; incandescent electric lights should be enclosed in double airtight glass covers, failing which, the rooms should be lit from outside, through airtight windows. Blankets and sand should be kept for extinguishing burning spirit, and water hydrants and hose for preventing extension of flame, steam jets being also useful. Non-inflammable outer garments should be worn by all employees. Outside staircases should be provided, as a means of escape, for all rooms above the ground floor. Ample space and free ventilation will lessen the risk of accidents. No meals should be taken in rooms where inflammable spirit is used. Periodical medical inspection of women and young persons exposed to the fumes is desirable.—C. S.

Silk; Weighted ——. R. Gnehm and W. Dürsteler. XXIII., page 1069.

Serine; Resolution of racemic ——, *into optically active components.* E. Fischer and W. A. Jacobs. XXIV., page 1070.

ENGLISH PATENTS.

Silk-like threads; Manufacture of ——, *and of cellulose solutions therefor.* E. W. Friedrich, Blaton, Belgium. Eng. Pat. 6072, March 13, 1906. Under Int. Conv., March 13, 1905.

SEE Fr. Pat. 364,066 of 1906; this J., 1906, 980.—T. F. B.

Cellulose threads; Method of producing ——. E. Thiele and Soc. Gén. de la Soie Artificielle Linkmeyer, Brussels. Eng. Pat. 15,133, July 3, 1906.

A CONCENTRATED solution of cellulose in ammoniacal copper oxide solution is allowed to pass through comparatively wide apertures (of about 0·5 mm. in diameter) into water or water mixed with a small proportion of acid or alkali. The threads thus formed are, after being stretched in the bath, drawn through an alkaline bath of either cold caustic soda of 39° B. or a boiling solution of less concentration. They are finally treated with acid. —J. C. C.

Dyeing and printing; Preparation of new products for use in ——, *and as pigments, and their applications.* E. Feilmann, London. Eng. Pat. 25,693, Dec. 11, 1905.

THIS invention relates to the manufacture of products for use in dyeing and printing, and as pigments, by forming a dyestuff or the like in an aqueous medium containing casein or paracasein. The dyestuff may be precipitated as a colloidal preparation by suitable treatment. The method of dyeing, by subjecting the material to such a solution as the above, is also claimed.—B. N.

Bronze prints; Manufacture of ——. C. A. R. Ludewig, Hamburg. Eng. Pat. 11,951, May 22, 1906. Under Int. Conv., Aug. 21, 1905.

THIS invention relates to a method of producing bronze printings, and consists in making a mixture of powdered bronze and a suitable filling material, the mixture being applied to a surface previously printed with colour, whilst it is still in a damp state.—B. N.

Discharging of dyed textile fibre; Imps. in, and manufacture of discharging pastes for use in the ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 7617, March 29, 1906.

SEE Second Addition to Fr. Pat. 355,117 of 1905; following these.—T. F. B.

Washing machines [for textiles]; Rotary ——. H. Stützel, Zürich. Eng. Pat. 26,585, Dec. 20, 1905.

A DOUBLE-DRUM washing machine is claimed in which the inner drum has the walls indented to form troughs, which can be closed on the outside by plates or the like, and which are provided with spraying holes. A great improvement is claimed as compared with washing machines in which perforated sheet metal or perforated tubes form a cylinder, which rotates within the outer drum.—H. BE.

Drying loose wool, yarn, and the like in the form of cops or of strands; Process and apparatus for ——. R. Jahr, Gera, Germany. Eng. Pat. 12,938, June 2, 1906.

SEE Fr. Pat. 366,608 of 1906; following these.—T. F. B.

Dry-cleaning fabrics with the aid of benzene or other volatile fat solvents; Process and cleansing composition for ——. E. Weiss, Weiden, Bavaria. Eng. Pat. 12,080, May 23, 1906.

SEE Fr. Pat. 366,547 of 1906; this J., 1906, 981.—T. F. B.

UNITED STATES PATENTS.

Leaf or fabric; Thin ——, *and method of making the same.* H. R. Gregory, New York, Assignor to W. A. Ker, Brooklyn, N.Y. U.S. Pat. 826,781, July 24, 1906.

ONE-quarter lb. of "soluble cotton" is dissolved in 1 gal. of "amyl oil," and a "colouring matter," such as "bronze," is added in the proportion—one part to four parts of the solution. After thoroughly mixing, the solution is poured on to a liquid, such as water, heavier than the oil. The latter evaporates, leaving a thin leaf on the surface of the water.—B. N.

Textile and paper base. V. A. de Perini, Assignor to C. C. Stockle and T. M. Kentish, Rio de Janeiro, Brazil. U.S. Pat. 831,521, Sept. 18, 1906.

COMMERCIAL fibre, as an article of manufacture, is obtained from the bark of the developed plant *Canhamo brazilensis perini.* Reunited fibres from the plant, and paper-pulp from the core of the plant are also claimed.—B. N.

Silk fabrics; Apparatus for ungumming ——. P. Schmid, Basle, Switzerland. U.S. Pat. 831,097, Sept. 25, 1906.

SEE addition of Jan. 21, 1905, to Fr. Pat. 345,173 of 1904; this J., 1906, 475.—T. F. B.

Dyeing apparatus. G. A. Friedrichs, Assignor to C. A. Proulx, Woonsocket, R.I. U.S. Pat. 832,472, Oct. 2, 1906.

A TUB or vat is provided with an opening in its bottom, and connected to the opening is a conduit, through which a spindle extends into the tub. A "spider," located in the conduit, is fixed on the spindle. The latter, inside the tub, passes through a perforated tube, surrounding which is a basket with an open-work side, the base of the basket resting against and engaging with the "spider" of the spindle. Mounted on the end of the latter is a nut, which also rests against the end of the perforated tube. A movable cover, comprising a tubular portion closed at its outer end and resting over the nut and the foraminated tube, and a flange, surrounding the tubular portion, close the end of the basket.—B. N.

Transfer-printing. J. F. Thorpe, Assignor to Wm. Briggs and Co., Ltd., Manchester. U.S. Pat. 831,582, Sept. 25, 1906.

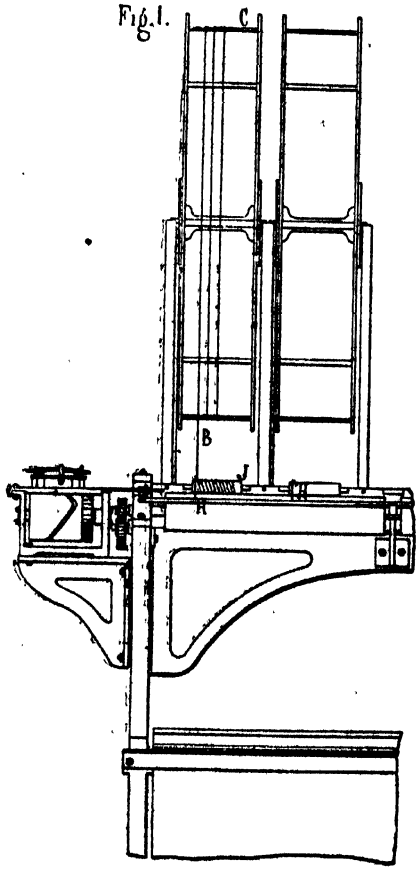
The required design is applied to a suitable supporting medium by means of a mixture of "indigo salt T" and resin, the latter acting as a carrying medium, and the design is then transferred to the fabric by the action of heat. By the addition of an alkaline solution, the resin is converted into soap and may be readily removed, "the indigo salt T" being converted into indigo, thus leaving it indelibly printed on the fibres of the fabric.

—B. N.

French Patents.

Filaments of artificial silk of relatively great diameter, suitable for use in the unspun condition; Process and differential apparatus for producing ——. V. Krafft. Fr. Pat. 363,922, Feb. 13, 1906.

Fig. 1.



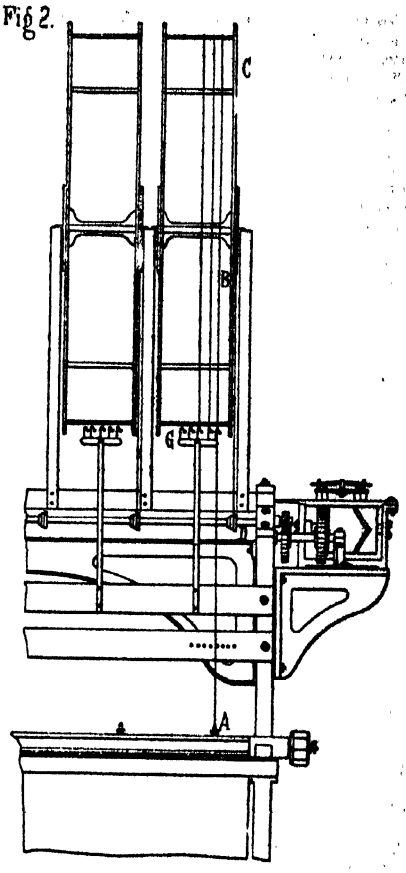


Fig. 2.

Filaments, B (see Figs. 1 and 2), of collodion-silk are drawn by winches, C, from forming nozzles, A, of relatively great, *viz.*, 30—500 "deniers," diameter. After passing spirally several times round the winches, through guide-combs, G, (Fig. 2) they are taken over travelling guides, H, (Fig 1) and wound upon revolving bobbins, J (Fig 1). The circumferential speed of these is made to exceed to any required degree that of the winches, in order to stretch the filaments as they leave the latter in a partially dried state.—E. B.

Glass rollers for use in manufacturing artificial threads. J., W., and H. Röhrens. Fr. Pat. 364,269, March 15, 1906.

The solid glass rollers which are largely employed in the processes of manufacturing artificial threads for the purpose of conducting the latter through baths of ammonia, sulphuric acid, caustic soda, &c., are easily broken, and when broken have to be replaced in their entirety. It is proposed, according to this invention, to construct them in several easily replaceable parts, using for the bodies of the rollers hollow glass cylinders, supported upon rods of metal or other acid-resisting materials enclosed in sleeves or rings of indiarubber. The supporting rods are fixed in the ends of the rollers, by nuts and screws, which, on account of their being the most liable to become damaged, are made of copper or acid-proof bronze or other suitable material.—E. B.

Textile fibres [Artificial silk] from cupro-ammoniacal solutions of cellulose; Process of manufacturing lustrous ——. Soc. anon. "La Soie Nouvelle." Fr. Pat. 365,057, April 10, 1906. Under Int. Conv., April 11 and July 14, 1905.

A cupro-ammoniacal solution of cellulose is forced, under a pressure of 1½—2 atmospheres, through a draw-plate containing holes 0·15—0·12 mm. in diameter, into a precipitating bath of glycerin, rendered acid or alkaline

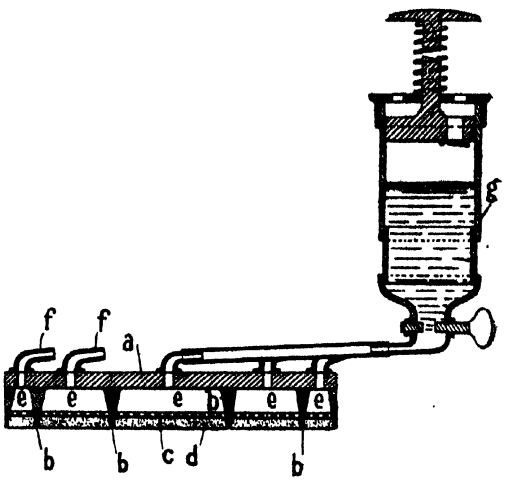
for this purpose consists of glycerol-monosulphuric acid (37½ parts), glycerol (25 parts), and water (37½ parts). The filaments thus produced may next be passed through a "neutralising" bath of a salt, such as common salt, sodium acetate, &c., capable of reacting with the acid still retained by them. If not decolorised by this treatment, they may be given a further passage through a dilute bath of sodium bisulphate, which readily removes the copper left in them. They are afterwards rinsed in water. The copper may be removed by the action of glycerin alone in the forming and washing baths. The filaments obtained by this method are stated to be more silk-like than any hitherto produced.—E. B.

Cotton tissues; Process of chemically treating [Mercerising] ——, with the object of rendering them stronger and more compact, and capable of being dyed in deeper and faster colours. P. Beresin. Fr. Pat. 364,577, March 20, 1906.

COTTON yarns and tissues are treated for a length of time, which may extend to half an hour, with either: (1) a cold solution of caustic soda-lye at about 40° B.; or (2) a hot solution at about 25° B. of a mixed ammonia-soda-lye, made by adding a solution of ammonia to one of caustic soda prepared by causticising sodium carbonate with lime and allowing the calcium carbonate produced to settle out. Considerable heat is evolved when the alkali solutions are mixed together, and a "double salt" of ammonia and sodium is, it is stated, formed. The cotton materials treated with these solutions, especially those acted upon by the second one, after being washed, &c., can be dyed in more intense shades than the same materials in the untreated state, and the dyeings are more durable and faster to light than those obtained on the latter. The second process is, it is stated, more economical than the first.—E. B.

Cotton and ramie slubbing; Process of mercerising and dyeing ——. E. Steiner. Fr. Pat. 364,965, April 5, 1906.

THE slubbing, sliver, rovings, &c., of cotton or ramie, to be mercerised and dyed, is wound upon metal tubes which are slipped over the winding bobbins. The tubes, which are fluted if they are to be used in dyeing, are then drawn from the bobbins, and placed upon wooden supporting rollers. They are thus put into an apparatus where they are treated under high pressure with the usual scouring agents, or advantageously with compounds, such as sodium sulphide and sodium sulphoricinoleate, which act as efficient scouring agents whilst increasing the strength of the fibres. After being rinsed and drained, the slubbing whilst still in the wet state, is unwound from the tubes, made up in the form of hanks, and thus mercerised and dyed in the same manner as ordinary hanks of yarn. It is next again wound upon the tubes, and dried thereon. It is then ready for spinning into yarns. If the slubbing is to be dyed without being mercerised, the tubes upon which it is carried are placed in an apparatus in which the dye-liquors are circulated through it.—E. B.



Mercerising and dyeing cotton or ramie slubbing; Process of ——. E. Steiner. First Addition, dated May 1, 1906, to Fr. Pat. 364,965, April 5, 1906 (see preceding abstract).

THE slubbing is opened out with a suitable machine, and the fibres and waste thus obtained are mixed in different proportions with waste silk, and spun in the ordinary manner. Brilliant fibres, consisting of a mixture of waste silk and mercerised cotton, are thus obtained.
—B. N.

Dyeing and binding threads together to form "baste" ribbons, and drying the same, producing several such ribbons simultaneously; Process for ——. C. Jeschke. Fr. Pat. 364,664, March 23, 1906.

SEVERAL "baste" ribbons are simultaneously manufactured by drawing "groups" of threads, each containing a sufficient number of the latter to form a ribbon of the desired width, successively through a separating comb, a bath containing an agglutinant to which a dye-stuff may be added to colour the threads, between rollers to press them together into sheets, over a drying apparatus; then, if desired, between calender rollers to give them a smooth appearance, and finally on to a roller upon which the ribbons thus simultaneously made are wound apart from one another.—E. B.

Block for printing tissues in several colours. E. Gamby. Fr. Pat. 363,977, March 8, 1906.

THE printing-block which forms the subject of this invention is constructed in such a manner as to be capable of printing tissues simultaneously in any required number of colours. It consists of a plate or board, *a* (see figure), to the underside of which are screwed vertical partitions, *b*, corresponding in shape with the outlines of the pattern to be printed, the colour chambers thus made being filled in at the bottom with a perforated sheet, *c*, beneath which is placed a layer of felt, *d*, forming the printing-surface. Each of the chambers communicates by means of an aperture, *e*, in the board, *a*, above it, through a connecting nozzle, *f*, and indiarubber tube, with a vessel, *g*, containing the printing-mixture to be applied from it, as many such vessels, *g*, as there are colours to be printed, being provided. The block, along with the colour vessels, is placed in a supporting frame, suspended by springs from a travelling press. The tissue to be printed is stretched below the block, which is lowered upon and held against it by suitable means. After printing, the block is lifted, and the press is moved forward through a distance equal to its length. Another length of the tissue is printed in the same manner as before, and the press is again moved forward.—E. B.

Discharging on coloured grounds; Method of ——. Badische Anilin und Soda Fabrik. Second Addition, dated May 14, 1906 (under Int. Conv., Feb. 28, 1906), to Fr. Pat. 355,117, June 9, 1905.

SALTS of organic ammonium bases, or the bases themselves, are mixed with the colour-discharging agents, such as formaldehyde-sulphoxylates, either pure or in combination with formaldehyde-bisulphites.—B. N.

Decolorising textile fibres; Process for ——. Badische Anilin und Soda Fabrik. *Fr. Pat. 366,701, May 30, 1906. Under Int. Conv., Feb. 24, 1906.

SEE Eng. Pat. 12,517 of 1906; this J., 1906, 867.—T. F. B.

Drying of textile materials; Process and arrangement for the ——. M. R. Jahr. Fr. Pat. 366,608, May 26, 1906.

THE moist air, leaving the chamber in which the material has been dried, is again brought into contact in another chamber with the dry material, until the latter has attained

its normal degree of humidity, and the air is then withdrawn from the apparatus. Before each compartment receiving the material to be dried, is a chamber divided by a partition into two channels, one of which is heated and the other not, and the air may be passed through either of these by suitably opening or closing the channels. The external air entering through a channel not heated, as well as the moist air entering the dry chamber, serves to cool the dried material.—B. N.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 985.)

Chlorine and hydrogen; Interaction of ——. C. H. Burgess and D. L. Chapman. Chem. Soc. Trans., 1906, **89**, 1399—1434.

The authors have ascertained that the phenomenon, hitherto known as photochemical induction, is not exhibited by a mixture of chlorine and hydrogen in the absence of such impurities as are capable of being destroyed by the insolation of the gases. What has been known as the "decay" of the activity of the gases in the light, caused by leaving them, when active, to stand in the dark over water, has now been traced to the renewed presence of impurities taken up from the water. The inhibiting impurity can be removed from the gases, without the aid of light, by raising the temperature to 100°C. The addition of minute quantities of ammonia, or of a substance yielding ammonia, has been found to cause the gases to exhibit the so-called induction period. The effect of the presence of a minute quantity of suitable impurity in inhibiting the combination of the gases for a time cannot yet be satisfactorily accounted for. The co-efficient of the extinction of light by a mixture of hydrogen and chlorine in equivalent proportions is almost the same as by that of equal volumes of oxygen and chlorine.—A. S.

Nitric oxide and air; Solubility of —— in sulphuric acid. O. F. Tower. Z. anorg. Chem., 1906, **50**, 382—388.

The author has determined the solubility of nitric oxide and of air in pure sulphuric acid of various concentrations, at different temperatures. The determinations were made in an absorption apparatus fashioned after the style of a Bunsen eudiometer. With 98 per cent. acid no constant results could be obtained in the case of nitric oxide, mercury being dissolved by the sulphuric acid in presence of this gas. Concentrated sulphuric acid, therefore, should never be used in the Lunge nitrometer. Constant results were, however, obtained with sulphuric acid of concentrations between 50 and 90 per cent., the volume of nitric oxide absorbed per c.c. of acid at 18°±1° C. and 760 mm. being as follows: 90 per cent. acid, 0·0193 c.c.; 80 per cent., 0·0117; 70 per cent., 0·0113; 60 per cent., 0·0118, and 50 per cent. acid, 0·0120 c.c. The corresponding results for the solubility of air in sulphuric acid were: 98 per cent. acid, 0·0173 c.c.; 90 per cent., 0·0107; 80 per cent., 0·0069; 70 per cent., 0·0055; 60 per cent., 0·0059, and 50 per cent. acid, 0·0076 c.c.; in this case, constant results were obtained even with the 98 per cent. sulphuric acid. The results obtained show that, in the determination of nitrates, nitrites, or oxides of nitrogen by means of Lunge's nitrometer, the solubility of nitric oxide in sulphuric acid of a concentration below 90 per cent. is so small that it can be neglected, provided not more than 10 c.c. of acid are used. The solubility of air in sulphuric acid is also so small as to be negligible. The best results will be obtained with sulphuric acid of 70 per cent. strength, in which both nitric oxide and air show a minimum solubility.—A. S.

Calcium sulphate; Solution of —— in salt solution. G. Arth and Crétien. Bull. Soc. Chim., 1906, **35**, 778—782.

Five grms. of pure sodium chloride and 5 grms. of precipitated calcium sulphate were heated in a thermostat with 200 c.c. of a solution of sodium chloride saturated at the ordinary temperature, for 15 hours (which is sufficient to produce equilibrium), at temperatures ranging from 0° to 99° C., and the calcium, sulphuric acid and chlorine were determined in the resulting solution; the chlorine content of the solution increased fairly regularly from 15·253 grms. per cent. at 0° to 17·128 grms. at 99°. The calcium content increased regularly from 0·1838 grm. per cent. at 0°, to 0·2309 grm. at 71°, and then decreased to 0·2068 grm. at 99°. The sulphuric anhydride attained its maximum, 0·2993 grm. per cent., at 62·5°, and then fell sharply to 0·2204 grm. at 65°, whence it dropped gradually to 0·2007 grm. at 99°. It is thus impossible to deduce the solubility of calcium sulphate in salt solution by determining one of the constituents. The results were similar when no excess of sodium chloride was present.—T. F. B.

Salts of iron, chromium, tin, cobalt, nickel, and zinc; Hydrolysis of —— in presence of iodides and iodates. S. E. Moody. Amer. J. Science, Silliman, 1906 [4], **22**, 176—184. Chem. Centr., 1906, **2**, 1106—1107.

The action of potassium iodide and iodate on aluminium chloride or sulphate can be utilised for the iodometric determination of aluminium (this J., 1905, 1033). Ferrous and ferric salts are also hydrolysed by the iodide-iodate mixture, the former being also oxidised. $Fe_2(SO_4)_3 + 5KI + KIO_3 + 3H_2O = 2Fe(OH)_3 + 3K_2SO_4 + 6I$. The hydrolysis is complete after boiling the solution for 30 minutes. Sulphates of chromium, tin, cobalt, and nickel are acted upon in a similar manner. In the case of stannic salts, complete hydrolysis can be effected at the ordinary temperature if the iodine be removed as it is liberated. Cobaltous hydroxide is oxidised to cobaltic hydroxide by excess of iodate; a corresponding reaction does not take place with nickelous hydroxide. Zinc sulphate is hydrolysed only to the extent of 80·13 per cent., a basic sulphate, $Zn_3(OH)_6SO_4$, being formed.—A. S.

Silicates; Chemistry of ——. E. Jordis. Z. angew. Chem., 1906, **19**, 1697—1701.

The author has investigated the properties of silicates formed in the wet way. Silicic acid being so weak an acid, is but slightly dissociated in solution; but its salts are highly dissociated, and the more so the less soluble they are, so that it is only possible to obtain them in the presence of other salts of the same metals, added to check the dissociation. Pure colloidal silicic acid does not exist alone—only in presence of traces of other substances (called by the author "Sol-formers"). Gelatinous silica, and hence also the dry silica prepared from it by evaporation, is never pure, but retain chlorine, alkali, iron, or organic substances. Pure silica is obtainable by decomposing silicon tetrachloride, and expelling traces of chlorine from the product by Meyer's method of long ignition at 1000° C. Orthosilicates of the alkalis or alkaline-earths could not be obtained in the wet way—only metasilicates; but fusion processes yielded orthosilicates. Bisilicates of the alkaline-earths appear to exist, more soluble than the monosilicates. Alkaline-earth hydroxides react with alkali silicates, precipitating alkali-free silicates of the alkaline-earths. Possibly this reaction occurs during the hardening of cements. When solutions of alkali silicates and of salts of the heavy metals (iron, copper) react, the results are very complex, and are no doubt rendered so through the varying degrees of hydrolysis of reagents and products. On mixing equivalent quantities, not only is precipitation incomplete, but acid and base are not equivalent to one another, either in precipitate or filtrate. If to the acid filtrate alkali be gradually added, a further precipitate falls, which when neutrality is reached contains all the iron, but only part of the silica present; and this precipitate will absorb a considerable quantity of additional alkali before the solution becomes alkaline to test-papers. The colours of the precipitated iron and copper silicates vary with the content of water, and still more with the temperature. Some of the copper silicates are very bright, but they have only slight covering power and are not likely to become of any industrial importance.—J. T. D.

Sulphur; A hydrate of ——. W. Spring. Rec. trav. chim. Pays-Bas, **25**, 253—259. Bull. Acad. roy. Belg., 1906, 452—459. Chem. Centr., 1906, 2, 1036.

The author finds that Debus's sulphur δ, formed, together with ordinary sulphur and the polythionic acids, by the action of hydrogen sulphide on sulphurous acid in aqueous solution, is not a new allotropic form of sulphur, as stated by Debus (J. Chem. Soc., 1888, **53**, 282—6), but hydrate of sulphur. The precipitated sulphur from the reaction was washed by dialysis, and dried *in vacuo* until the weight was constant, a yellowish, partly transparent substance showing a conchoidal fracture being obtained. This contained about 51·6 per cent. of sulphur soluble in carbon bisulphide. The portion insoluble in carbon bisulphide begins to lose water when heated to 80° C., and the total quantity of water evolved at the melting point of sulphur corresponds to the formula, S_8,H_2O. The hydrate when pressed into the form of a rod has the sp. gr. 1·9385 at 19°/4° C., and loses 1·33 per cent. of water when left standing over sulphuric acid for seven months; the powdered hydrate under similar conditions loses 2·41 per cent. of water. As the hydrate loses water, its specific gravity increases. If the dehydrated product be left in contact with water, its specific gravity becomes lower, indicating that there is a form of sulphur capable of uniting directly with water. After partial dehydration in an exsiccator, the pulverulent hydrate contained 3·1 per cent. soluble in carbon bisulphide, and the compressed hydrate 5·8 per cent.—A. S.

Phosphorus; Investigations on ——. A. Siemens. Arbb. Kais. Ges.-A., **24**, 264—304. Chem. Centr., 1906, 2, 1084—1085.

The author points out that there is no chemical reaction of yellow phosphorus which is not also given by red phosphorus. The differences in the behaviour of the two modifications are due to the fact that the red phosphorus reacts at a much slower rate than the yellow modification. With regard to the cause of phosphorescence, the author confirms the statement of Jungfleisch (this J., 1905, 252) that this is due to the formation of a volatile lower oxide of phosphorus. (Compare Thorpe and Tutton, J. Chem. Soc., 1890, **57**, 569.)

Detection of yellow phosphorus in commercial red phosphorus.—The following process was found to give satisfactory results. Five grms. of the sample are boiled for half an hour with 150 c.c. of benzene under a reflux condenser. After cooling, the solution is filtered from the undissolved red phosphorus, and 1 c.c. is shaken vigorously in a test-tube with 1 c.c. of ammoniacal silver solution (1·7 grms. of silver nitrate in 100 c.c. of ammonia solution of sp. gr. 0·992). If the sample contained no yellow phosphorus, the solution will give only a faint yellow coloration, but if yellow phosphorus be present, a reddish or dark brown coloration or a precipitate is produced. Regard must be paid only to the coloration produced during the first half-hour. Of the 5 grms. of red phosphorus taken for the test, 1·5 mgrms. are dissolved by the 150 c.c. of benzene, and the author suggests that this should be the highest permissible limit for the amount of soluble matter in commercial red phosphorus.

The author states that the work of Roozeboom on the phases of phosphorus shows that the view frequently put forward that red phosphorus is transformed into yellow by friction is incorrect. On striking or rubbing, red phosphorus is merely brought into a finer state of division, and this finely divided phosphorus is more soluble and chemically active than the ordinary red variety. This explanation is confirmed by the fact that the production of the more soluble phosphorus is not influenced by the weight of the grinding agent (large earthenware balls), but is favoured by the use of grinding stones (granite) with sharp edges. Scarlet phosphorus (this J., 1903, 494, 1225, and 1256; 1904, 17), also, is stated to be merely red phosphorus in a very fine state of division. Various points of difference between yellow phosphorus and the finely-divided red phosphorus are mentioned.—A. S.

Chromic acid; Electrolytic production of ——. J. Y. Johnson. From Badische Anilin und Soda Fabrik. Eng. Pat. 27,009, Dec. 27, 1905. XIA., page 1052.

Lime; Kilns for burning ——. W. E. Benton, Acton. Eng. Pat. 11,820, May 26, 1906.

The lime-kiln described is of the continuous type, and comprises a number of chambers that can be successively charged, fired, cooled, and emptied. Over the fire-bars of each chamber is an arch or flue of perforated fire-blocks, from which the hot gases pass either into a flue arranged lengthwise, between the rows of chambers and above the level of the kiln-floor, through openings controlled by suitable dampers, or else into outer longitudinal flues below the level of the kiln floor, being directed downwards thereto by sheet iron plates fitted into the doorways of the firing holes. Footplates are provided to close the openings from the firing hole into the outer flue. Both the upper and lower flues communicate with the chimney. Forced draught is supplied by suitable apparatus through a flue which runs the length of the kiln below the level of the kiln floor, and is provided with side flues controlled by doors, opening into the ash-pits.—W. C. H.

Lithium carbonate; Extraction of lithium as —— *from its ores.* C. Poulenc, Paris. Eng. Pat. 9971, April 28, 1906.

Nitrate of soda; Manufacture of ——, *and the recovery of by-products in connection therewith.* C. Stuart-Bailey, London. Eng. Pat. 19,189, Sept. 22, 1905.

By the process described, carbonaceous matter containing nitrogen is subjected to destructive distillation, to yield ammonia and other by-products. The combustible gases and waste heat derived from the distillation process are employed as the source of power for generating electricity with which to obtain caustic soda solution, hydrogen, and chlorine from brine. The hydrogen is passed through the incandescent carbonaceous matter to recover any residual nitrogen in it. The ammonia produced by the distillation process is passed with air or oxygen over a heated contact substance, preferably platinum, in successive steps, the nitric acid and ammonium nitrate thus produced being removed by the caustic soda solution obtained from the electrolysis of the brine, between each step and the succeeding one. The whole may be worked as a composite or continuous process, in apparatus suitably arranged for it.—W. C. H.

Nitrogen peroxide; Method of working combustion motors [explosion engines] in order to obtain —— as a by-product. F. Häusser. Fr. Pat. 366,604, May 26, 1906. Under Int. Conv., May 31, 1905.

THE combustible mixture of gases with air, or with air and oxygen, after compression is ignited in an explosion engine. When the mixture has attained its maximum temperature, it is cooled suddenly by a jet of water to just below the decomposing point of nitrogen peroxide. At this temperature however the gaseous mixture still has considerable pressure, and it is allowed to expand and perform mechanical work in the usual way.—E. S.

Flowers of sulphur; Process and apparatus for the manufacture of ——. E. Rasse-Courbet. Fr. Pat. 366,280, May 16, 1906.

THE mineral containing sulphur or "orpiment (arsenic sulphide)" is melted in receptacles in the upper part of a furnace, from each of which the melt is run into a closed muffle immediately beneath. From the heated muffles, the vapours are drawn into chambers, having conical bottoms, in which condensation is principally effected, and thence into and through other chambers in which further condensation takes place, whence the gases pass into a coke tower to be washed, and have exit finally into a pipe for combustion. The ore receptacles, the muffles, and the communicating channels are all heated by circulation of gases of combustion from a single fire-place.—E. S.

Oxygen; Apparatus for generating ——. The Roessler and Hasslacher Chem. Co. Fr. Pat. 366,524, May 23, 1906. Under Int. Conv., Feb. 8, 1906.

THE apparatus consists of a cylinder having double sides, inclosing some such non-heat conducting substance as asbestos, charged with a certain quantity of water, and having suspended within it another, considerably smaller cylinder, open at the bottom, containing cartridges of, for instance, compact sodium peroxide, or other substance that will yield oxygen on coming into contact with water. The cartridges are supported by a permanent spring resting on the bottom of the outer cylinder, and the cover of the inner cylinder is formed with a central tube, attached to the cover of the casing. This tube is continued upwards by a valve piece screwed into it, to which valve a flexible delivery tube for the oxygen given off may be attached. There is another valve in the cover communicating with the interior of the casing and the outer atmosphere. When both valves are closed, the water contained in the enclosing cylinder does not gain access to the charge in the inner cylinder; but on opening the valves, pressure in the latter cylinder is released, whereby water has access to the peroxide, and oxygen continues to be evolved as long as the valves remain open. The rate of evolution of the oxygen is under easy control, and it is stated that the apparatus may be put out of action for weeks by closing the valves. The cover to the casing is secured by two screws; but it is so constructed that it can, on partial rotation, be removed without removing the screws.—E. S.

Oxygen; Composition disengaging —— on contact with a liquid. The Roessler and Hasslacher Chem. Co. Fr. Pat. 366,526, May 23, 1906. Under Int. Conv., April 14, 1906.

IT is stated that when an alkali peroxide is decomposed by water in presence of a metallic oxide as catalyst, the production of a hydrate of the peroxide or of hydrogen peroxide is lessened, with increase of the amount of oxygen set free. Amorphous sodium peroxide, mixed with 5 per cent. of a metallic oxide, such as cupric, manganic, nickel, or ferric oxide, yields oxygen, and a small proportion of hydrogen peroxide on treatment with water, and the result is not materially affected by altering the proportion of the metallic oxide. But if sodium peroxide be melted with 5 per cent. of such a metallic oxide, the product yields, on treatment with water, oxygen with almost explosive violence, and no hydrogen peroxide is found in the caustic solution. If less than 5 per cent. of metallic oxide be melted with sodium peroxide, the subsequent reaction with water is proportionally less active. Thus, it is possible to prepare sodium peroxide with a catalytic body under such conditions as to give any desired activity in oxygen production on treatment with water. (See also U.S. Pat. 788,256 of 1905; this J., 1905, 546.)—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 985.)

Silicates; Chemistry of ——. E. Jordis. VII., page 1043.

ENGLISH PATENTS.

Glass; Manufacture of ——. J. A. Chambers, Allegheny, Pa., U.S.A. Eng. Pat. 15,293, July 5, 1906.

THIS patent refers to modifications of the apparatus described in Eng. Pat. 2879 of 1906 (this J., 1906, 427). In the present invention the pot furnace is divided into two chambers by a depending wall or mantle, which extends from the roof to a distance above the rotating table sufficient to allow of the passage of the pots beneath the mantle. One of these chambers, containing pots filled with glass ready for working, is provided with a door, through which full pots can be withdrawn, or empty pots replaced upon the table. The replaced empty pots pass, by the next rotation of the table, into the second or pot-heating chamber, where the chilled glass adhering to the pots is re-melted, before the pots again arrive, by a further rotation of the table, below the trough that supplies molten glass from the tank. Means are provided for heating this pot-heating chamber. By modifying the construction of the depending walls or mantles, the pot furnace can be divided into three portions; in the first the pots are filled with glass from the tank, and carried by the table into the second portion, which is open to form a drawing chamber, from which the empty pots are carried by the table into the third, or pot-heating chamber. To ensure better and more uniform heating of the pots at all stages of the process, heating flues may be arranged below the rotating table, and instead of pots placed on the table, depressions or cups may be made in it to hold the glass, and the cups connected by openings, to maintain a constant level.—W. C. H.

Furnaces; Smelting, crucible, heating, annealing, and like ——, *and kilns for burning and glazing pottery, and for other like purposes.* The Incandescent Heat Co., Ltd., and A. Smallwood. Eng. Pat. 18,877, Sept. 12, 1905. X., page 1049.

Kilns employed for burning or fixing the colours or glaze upon glass or earthenware, and other materials, applicable also for other purposes. H. Thornton, R. N. Sharp, and J. H. Ingle, Leeds, and L. W. Stanley, Bromley, Kent. Eng. Pat. 25,639, Dec. 9, 1905.

THIS patent describes a modification of the apparatus described in Eng. Pat. 28,078 of 1904 (this J., 1906, 122), in which the furnace chamber is heated by the combustion of gases issuing from jets arranged on each side of the hearth. In the present modification it is proposed to use a combustible mixture of air and gas or hydrocarbon vapour, in which the air is in excess of the amount required for complete combustion of the gas or vapour. This mixture is supplied to the jets or burners at a speed greater than the speed of propagation of the flame, ignition occurring by impact of the mixture on a refractory

hood or cap placed over the nozzle of the burner. The firing compartment is provided with an arched top, and with guides for supporting the tray, on which the articles to be fired are placed. The burners pass through holes in the floor of the compartment, and each is provided with a perforated hood or cap, which causes ignition of the combustible mixture at or near the point of impact, and is stated to produce a flameless combustion. Between the underside of the tray and the surface of the floor is a space to allow for the hoods over the burners, which may be filled and made level with asbestos or other refractory material, which also prevents the flame escaping too rapidly from the perforations of the caps.—W. C. H.

UNITED STATES PATENTS.

Glass sheets; Manufacture of ——. W. L. Clause, Sewickley, and H. K. Hitchcock, Tarentum, Pa. U.S. Pat. 832,842, Oct. 9, 1906.

THE process described consists in causing glass to flow through a slot or orifice, and dividing the exuding stream into two or more streams by the application of tension in two or more directions at an angle to each other. The outer portions of the exuding stream are drawn in directions at an angle to, and out of the line of flow, whilst the core or inner portions of the stream are drawn approximately in the direction of flow of the glass, more glass being exuded from the orifice than is sufficient to form the articles required.—W. C. H.

Glass; Apparatus for the manufacture of sheet ——. H. K. Hitchcock, Tarentum, Assignor to C. W. Brown, Pittsburg, Pa. U.S. Pat. 832,860, Oct. 9, 1906.

THE apparatus described comprises a receptacle for glass, provided with a discharge slot, with outwardly flaring walls, which slot can be adjusted relatively to the height of the glass in the receptacle. A spout or channel extends from the glass-containing receptacle, and means are provided for regulating the temperature of and flow of glass in the channel. The glass is drawn away from the slot at the same rate as it passes through it. The mean axis of the sheet is maintained in approximately the same plane, regardless of the variations in thickness, and the sheet passes between pairs of driven rollers constructed to yield in planes at right angles to their axes, without distorting their peripheries, and without shifting their axes of rotation. The connections from the driving mechanism to the rollers are arranged to have a torsional strength less than the frictional bite of the rollers on the sheet. A cutter is provided to move either transversely to, or in the same direction as the sheet, and at the same rate, and means are also provided for receiving and carrying away the severed sections of the sheet.—W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

ENGLISH PATENTS.

Wood; Apparatus for impregnating or colouring ——. F. Pärr and J. Kopetz, Vienna. Eng. Pat. 21,902, Oct. 27, 1905.

THE apparatus described is of the class in which discs, into which liquid under pressure can be introduced, are forced against the ends of the logs. Between the packing rings of the pressure discs and the end surfaces of the log, intermediate rings can be inserted, which hold the packing for the end surfaces securely in position in annular grooves, and also, if desired, by rims on the interior edges of the intermediate rings. To purify the impregnating liquid, filters can be arranged in front of the end surfaces of the log, and within the intermediate rings. The pressing discs are connected with their supports by means of ball and socket joints to enable the discs to be forced tightly against the intermediate rings, when the end surfaces of the logs are not parallel.—W. C. H.

Cement. J. T. South and G. Payne, Brighton, and E. G. Payne, London. Eng. Pat. 13,232, June 8, 1906.

FOR the improved cement, chalk, albo-carbon or naphthalene, sodium sulphate or other suitable alkali salt, zinc sulphate, alum, and coke-breeze or coal ashes, are mixed together in a powdered condition, either dry or with water, and the sediment dried and powdered. This mixture is afterwards mixed with Portland cement and sand, and the whole mixture is then ready for use as cement.—W. C. H.

UNITED STATES PATENTS.

Stone, artificial; Manufacture of ——. J. Purvis and T. Rouse, London. H. C. J. Purvis, executrix of J. Purvis, deceased, and T. Rouse, Assignors to W. W. Tait, Philadelphia. U.S. Pat. 831,296, Sept. 18, 1906.

SEE Eng. Pat. 3294 of 1903; this J., 1903, 629.—T. F. B.

Wood; Process of preserving ——. J. T. Logan, Texarkana, Texas. U.S. Pat. 831,793, Sept. 25, 1906.

WOOD poles are treated in a closed vessel with live steam until the sap has evaporated. The vessel is then exhausted and simultaneously heated with dry heat, after which zinc chloride is injected and forced into the wood by pressure. The poles are then kiln-dried, and the ends treated in quick succession with a bath of hot creosote, followed by a bath of cold creosote.—A. G. L.

Pulp, wood, &c.; Method of treating ——, *and the resulting material.* C. F. Mabery, Cleveland, Ohio. U.S. Pat. 832,799, Oct. 9, 1906.

PULP, wood, and analogous substances are waterproofed and rendered tough and impervious by treating them first with rosin oil, and then with a solution composed of a vegetable gum, *e.g.*, copal gum, a drying-oil or other binder, and a solvent.—A. G. L.

X.—METALLURGY.

(*Continued from page* 991.)

Steel; Manufacture of —— *in the basic Siemens-Martin furnace.* W. Schmidhammer. Stahl und Eisen, 1906, **26**, 1247—1249.

THE article is based on one by A. Mignot in the "Comptes Rendus mensuels de la Société de l'Industrie minérale" (May, 1906), which deals with the basic process in France. The basic process is continually replacing the acid process, on account of its elasticity in permitting different ways of working, and allowing of the use of all sorts of raw materials. It is usual to decarburise completely and then to carburise again by suitable additions. But since 1891 one large works has stopped decarburisation when the required carbon content has been reached. This method is used in making medium hard steels with 0·35 per cent. of carbon from a mixture of 70 per cent. of scrap and 30 to 40 per cent. of pig-iron containing, on the average: phosphorus, 0·58; sulphur, 0·17; carbon, 3·4; silicon, 1·9; and manganese, 1·6 per cent. In making hard steel with 0·65 to 0·70 of carbon for cable wire, decarburisation is carried to the 0·35 point, and the steel then re-carburised by adding ferromanganese or ferrosilicon. The slags are rendered liquid by the addition of fluorspar. In another case soft steel was made from ore and pig-iron containing: carbon, 2·4; silicon, 0·7; manganese, 0·2; phosphorus, 1·4; and sulphur, 0·3 per cent. The hearth was lined with powdered limestone, and covered with limestone in pieces (6 to 7 per cent. of the pig-iron); on this was placed hæmatite ore (10 per cent.), and the whole covered with the pig-iron. After melting down, the slag was removed, another 8 to 10 per cent. of ore was added, as well as burnt limestone and 0·1 to 0·2 per cent. of 80 per cent. ferromanganese, and the whole cast after adding another 1 to 1·25 per cent. of ferromanganese. The steel obtained

contained: carbon, 0·11 per cent.; manganese, 0·40; phosphorus, 0·028; sulphur, 0·052; and a trace of silicon. The basic furnace may also be used to purify pig-iron for the acid process. In this case the hearth is charged with layers of pig-iron, hæmatite ore in large lumps (7 to 8 per cent. of the pig-iron), powdered limestone (10 to 15 times the weight of the silica produced) mixed with fluorspar (2 per cent. of the pig-iron), and more pig-iron on top. Just before casting 4 per cent. of ferromanganese is added. By adding 20 to 30 per cent. of scrap to the charge, ore and flux may be saved. In this way a pig-iron with carbon, 4 per cent.; silicon, 0·5; manganese, 4·5; phosphorus, 0·05; and sulphur, 0·02 per cent., gave a product with carbon, 2·1; silicon, trace; manganese, 2·4; phosphorus, 0·02; and a trace of sulphur. Pig-iron with 1·5 per cent. and more of phosphorus and 0·5 per cent. of sulphur is successfully treated by the Bonnand-Verdié method. In this the working is divided into two distinct phases: In the first a slag is produced very rich in lime, and containing 10 to 12 per cent. of silica, 3 to 4 of ferrous oxide, and 8 to 10 or less of total metallic oxides, together with most of the sulphur and a considerable part of the phosphorus. It is rendered sufficiently liquid by adding fluorspar. In the second phase the phosphorus is completely removed by a slag similar in basicity to the first but with more of the lime replaced by ferrous oxide, of which 15 per cent. may be present. This process has been further developed by working it in three stages. In the first most of the silicon is eliminated by forming a very silicious slag, which renders it easier to obtain the two very basic slags required in the two later stages in which sulphur and phosphorus are removed. In the basic process part or the whole of the pig-iron may also be replaced by ground coke in quantity corresponding to 1½ to 2 times the carbon in the pig-iron it replaces. To guard against its too early combustion, the coke is wrapped up in five times its weight of planings. For a charge of 20 tons about 500 kilos. of coke and 3000 kilos. of planings are used.—A. G. L.

Precipitate [Silver and gold]; Treatment of the ——, and manipulation of the tilting furnaces at the Redjang Lebong mines, Sumatra. S. J. Truscott. Inst. Min. and Metall., Oct. 18, 1906. [Advance proof.]

THE zinc-boxes are cleaned up twice a month; the precipitate and the "short zinc" are collected in separate tanks, and subjected to acid treatment, followed by washing with hot water, the consumption of acid being 0·117 lb. per lb. of precipitate treated and 0·514 lb. per lb. of short zinc. The washed precipitate is pressed and then calcined in quantities of about 500 lb. upon an iron tray over a wood fire; a good sample after calcination contained: gold, 8·19 per cent.; silver, 58·10; zinc, 5·90; lead, 3·80; selenium, 3·56; silica, 3·96; together with smaller proportions of iron, copper, and manganese, and 14·76 per cent. of undetermined matter. One hundred parts of clean precipitate require 16 parts of borax for fluxing; less clean precipitate requires 17·8 parts of borax, 9·0 parts of sodium bicarbonate, and 0·7 part of sand; the precipitate from the short zinc requires 22·7 parts of borax, 9·8 of sodium bicarbonate, and 4·8 parts of sand. The mixing is effected in a large enamelled drum, scrap iron being added when it is expected that matte will form, as is always the case when the short zinc precipitate is under treatment. The matte consists principally of silver selenide, which is readily reduced with sodium bicarbonate in presence of scrap iron. The furnaces are built in pairs, and consist of box-shaped castings lined with fire-bricks, two of the sides having trunnions carried in bearings on iron standards; the furnaces are tilted around these by means of worm and wheel gearing. The retort rests at an angle of about 30° from the horizontal upon an arch of fire-brick placed some inches above the level of the fire-bars. The furnace inside the fire-brick lining is 22 ins. square by 36 ins. high; the retort is 30 ins. long, 9½ ins. diameter at the back, 13¾ ins. at the middle, and 6½ ins. at the mouth, and the neck protrudes slightly through the front casting. The charge is from 150 to 200 lb., and when this is reduced, more is added until a total charge of 250 to 300 lb. is reached; after complete reduction, the slag is run off into slag pots and the metal into moulds of about 640 oz. capacity. The fire is started at 5 a.m. with charcoal; afterwards a mixture of charcoal and coke is used; with ordinary precipitate eight bars can be reduced and poured from each furnace in a day. From July to December, 1905, the amount of slag made was equivalent to 1·82 oz. per ounce of bullion, the average assay being gold, 9·5 oz.; silver, 299·3 oz.; the bullion contained 126·86 parts of gold to 818·54 parts of silver, together with selenium up to 3 per cent. and small amounts of copper, lead, and iron. The costs of smelting 2076 lb. of calcined precipitate during December, 1905, which yielded 3336·8 oz. of gold and 19,510·4 oz. of silver, amounted to £84 15*s.* 7*d.*, of which £12 10*s.* represented Europeans' wages, £8 6*s.* 8*d.* native labour, £22 0*s.* 8*d.* fuel, £10 16*s.* acid, £14 12*s.* 6*d.* borax, £1 9*s.* 9*d.* sodium bicarbonate, £13 retorts (three), and £2 general supplies; the total being equivalent to 0·098 pence per oz. of fine gold or 0·89*d.* per oz. of fine metal. The pot smelting previously employed cost less in pots and fuel, but much more in manipulation.—J. H. C.

Copper and phosphorus. E. Heyn and O. Bauer. Mitt. Königl. Materialprüfungsamt zu Gross-Lichterfelde West, 1906, **24**, 93—108.

THE authors have studied the influence of varying amounts of phosphorus on copper, and have prepared a number of micro-photographs. The structure is found to be perfectly homogeneous in the case of alloys containing not more than 0·175 per cent. of phosphorus. From this point onwards dark crystals are visible, surrounded in the first place by a lighter zone richer in phosphorus and then by eutectic veinings, which become visible with about 0·5 per cent. of phosphorus, and very marked with 0·75 per cent. The eutectic contains 8·27 per cent. of phosphorus, and has a melting point of 707° C. This point is well marked in all the mixtures of up to 14·1 per cent. of phosphorus, the melting point of which decreases at first from 1084° (that of pure copper) to 707° (that of the eutectic), and then rises again up to 1020°. This point is the melting point of the compound, Cu_3P, the existence of which is conclusively proved by measurements of the density and of electric potential. The phosphides of copper are found to be electronegative towards copper itself. In mixtures with from 0·5 to 14·1 per cent. of phosphorus the eutectic point at 707° disappears entirely, these bodies being mixtures of Cu_3P and (probably) Cu_2P_2. It is, however, impossible to prepare homogeneous bodies with more than 15 per cent. of phosphorus by melting, since for every temperature there exists a distinct maximum of phosphorus, beyond which that element is given off at that temperature, and for 1020° this maximum is 14·1 per cent. Bodies with a higher phosphorus content would have higher melting points, and hence no body with more than about 15 per cent. of phosphorus can be prepared by melting, as during the time required for the melting, any excess of phosphorus is volatilised. By heating mixtures of amorphous phosphorus with copper turnings at about 300° to 400°, friable masses with over 20 per cent. of phosphorus can be obtained. It is suggested that this heating be carried out in a series of crucibles filled with the mixtures, each one connected with the next by a tube reaching some way down, so as to minimise the loss due to escaping phosphorus vapour. Phosphorus hardens copper more than does tin, the compound, Cu_3P, being much harder than the corresponding tin compound, Cu_3Sn.—A. G. L.

Manganese-molybdenum alloys. G. Arrivaut. Compt. rend., 1906, **143**, 464—465.

THE author has extended his work (this J., 1906, 849) on this subject, and has made, by the aluminothermic method, alloys containing up to 75 per cent. of molybdenum. They are all silver-white, homogeneous, non-magnetic alloys, very hard, and more brittle as the content of manganese is higher. They are unaffected by air, are completely soluble in nitric acid, hot concentrated sulphuric acid, or fused alkali bisulphates. Acetic acid attacks those containing less than 63 per cent. of molybdenum, and hydrochloric acid attacks all, though it does not dissolve all completely. By the regulated

attack of alcoholic acetic acid or of hydrochloric acid the author has separated respectively from the alloys containing 35—45, 47—59, and 65—72 per cent. of molybdenum, the compounds, Mn_2Mo, MnMo, and $MnMo_2$. These are all steel-grey, non-magnetic, crystalline powders, stable in air at ordinary temperatures, attacked by chlorine, by water vapour at 250° C., and by oxygen or sulphur at a red heat. The alloys appear all to consist of one or other of these compounds in association with metallic manganese.
—J. T. D.

Lead smelting; Formation of fume in ——. F. O. Doeltz and C. A. Graumann. Metallurgie, **3**, 442. Eng. and Min. J., 1906, **82**, 584.

THE authors state that galena is far more volatile than lead oxide. At 860° C. it suffers a loss of weight of 18 per cent. in one hour. The formation of scaffolds of lead sulphide in lead blast-furnaces, and the fine needles of sulphide in the masonry of reverberatory furnaces are due to the sublimation and condensation of galena.

Lead sulphate is only slightly volatile, but is decomposed at about 1000° C. The lead sulphate found in flue-dust chambers is formed chiefly by the action of sulphur trioxide on lead oxide, or by oxidation of lead sulphide.
—A. S.

Sulphide ores; Roasting of —— to sulphates. R. Vondráček. Oesterr. Z. Berg.-Hütt., 1906, **54**, 437—441. Chem. Centr., 1906, **2**, 1089.

THE author has investigated the process of roasting sulphide ores, especially lead sulphide, to sulphates, and concludes from his results that for the formation of good yields of sulphates three conditions are necessary, viz., excess of air; the presence of contact-substances (catalysers), and a favourable temperature for the contact-process; and the presence of metal oxides and a suitable temperature for the formation of sulphates. These three conditions should be attained in succession. The gases formed on roasting must remain in contact for a certain time with the roasted material which acts as a catalyser, and during this period the temperature should not be raised above a certain point. In certain cases, where very stable sulphates are formed, the second and third phases may proceed conjointly, the sulphur trioxide formed being immediately absorbed by the metal oxide acting as contact-substance. All conditions tending to prevent rapid rise of temperature accelerate the formation of sulphates. The presence of inert gangue, of hygroscopic and combined water, and of carbonates thus all exert a favourable effect, as also does the presence of moisture in the air.

If it be desired to avoid the formation of sulphates in the roasting of sulphide ores, excess of air must not be used over that required for the combustion of the fuel gases and the oxidation of the ores, and the ore should be given a preliminary heating.—A. S.

Mineral production of India. Bd. of Trade J., Oct. 18, 1906. [T.R.]

THE quantity of minerals raised in British India in 1905 in mines regulated by the Indian Mines Act was as follows:—

	1904.	1905.
	Statute tons.	Statute tons.
Coal	7,561,338	7,762,779
Manganese ore	138,733	204,194
Mica	21,320	25,548
Limestone	50,847	93,170
Salt	107,413	94,078

The above table does not include the mineral production of Hyderabad and other great native states. The favourable geographical position of the Bengal coal fields, the excellent quality of the coal, and the easy mining conditions, give Bengal a great advantage over other provinces and the development of the coal industry has been remarkable. In 1898 the output was only 3,622,090 tons; in 1905 it amounted to 7,234,103 tons. The Mining Inspector traces a coke output to the extent of 258,958 tons, as carried by the railways, the coke being all produced in crude ovens, which do not average more than 40 tons of hard coke per 100 tons of coal. The East Indian Railway Company are installing a battery of modern retort ovens, with by-product recovery plant, at Giridih. Copper appears for the first time in the list of minerals raised from mines classed under the Indian Mines Act. Only 40 cwts. were raised, but a serious effort is being made to develop copper mining on a considerable scale. The export of manganese ore, in which India now takes a leading position, totalled 281,734 tons.

Australian mineral production and export. Mining World, Oct. 6, 1906. [T.R.]

THE production of gold in the various Australian States is as follows:—

	1904. Fine ozs.	1905. Fine ozs.
New South Wales	269,817	274,267
Queensland	639,151	592,620
South Australia	29,100	20,447
Tasmania	65,921	73,541
Victoria	765,600	747,166
Western Australia	1,983,230	1,955,316
Total	3,752,829	3,663,357

It is anticipated that the production will reach its former level during the present year. The exports of minerals during 1904 and 1905 from Australia were as under:—

	1904. £	1905. £
Alunite	925	6,750
Brass	512	796
Copper:		
Bars, &c.	220	4,973
Ingots	1,550,281	978,384
In matte	—	1,100,139
Ore	100,567	19,517
Bullion	3,693	—
Gold:		
Bullion, &c.	5,563,865	5,259,669
Ore, &c.	9,637	10,174
Specie	10,128,408	4,255,703
Iron and Steel:		
Bar, &c.	2,414	2,140
Girders, &c.	172	117
Lead:		
Pig	872,000	783,823
In matte	—	15,308
Sheet, &c.	16,116	29,643
Mercury	22	—
Ores:		
Antimony	503	5,260
Bismuth	17,910	24,009
Chromium	1,268	—
Cobalt	76	350
Iron	—	98
Molybdenite	5,432	8,372
Scheelite	1,980	10,409
Tungsten	128,179	123,042
Zinc blende	8,375	—
Platinum	—	825
Plumbago	165	188
Silver:		
Bullion, &c.	847,727	699,241
In matte	—	117,899
Silver-lead ore	564,025	236,461
Bullion	793,596	770,623
Spelter, concentrates, &c.	47,231	780,003
Tin:		
Ingots	611,820	765,221
Ore	132,042	202,508
Zinc, all kinds	1,484	1,989

Coal production, although confined principally to New South Wales, is steadily expanding, despite frequent

labour disputes and other difficulties. The value of the exports, other than interstate, in 1905, was £861,692 against £786,490 in 1904. The exports of coke represented a value of £3,105, New Zealand being almost the only customer. Shale production is likely to become a leading industry within the next few years, by reason of the large amount of capital invested in working the enormous deposits in the western portion of New South Wales. In 1904 the value of the exports was £18,897, which became increased to £28,304 in 1905, the Netherlands taking nearly the whole quantity.

Antimony production in 1905. Mining World, Oct. 6, 1906. [T.R]

The supply of ore marketed continues to be exceedingly small. China for the last five or six years has produced the greatest quantity of ore, but since June, 1904, there has been a heavy falling off in these shipments. The production of antimony as a by-product and from imported ores in the United States in 1905 amounted to 3240 short tons, valued at $705,787, as against 3057 tons, valued at $505,524, in 1904. The production of metallic antimony from domestic and foreign ores in the United States is about 500 short tons per annum, whilst that contained in hard lead has amounted to somewhat over 2500 short tons for the last four years. The total consumption of antimony in the United States in 1905 was 5712 short tons, compared with 4759 tons in 1904. Accurate figures showing the output of China, the source of largest supply, are not obtainable, as the empire does not collect mineral and metal statistics. From the most authoritative source—the importers of Chinese antimony—it is learned that the exports from China in the first six months of 1905 amounted to 2014 long tons, while the last half showed a material decrease. In 1904 the exports from China were 12,037 long tons, as against 7341 tons in 1903, 10,087 tons in 1902, and 3633 tons in 1901.

English Patents.

Furnaces; Smelting, crucible, heating, annealing, and like ——, and kilns for burning and glazing pottery and for other like purposes The Incandescent Heat Co., Ltd., and A. Smallwood, Loudon. Eng. Pat. 18,877, Sept. 19, 1905.

The invention consists essentially in arranging above a horizontal combustion chamber a heating chamber for a number of crucibles, an annealing chamber, and a chamber for reheating, &c., all these chambers being so connected to the combustion chamber or to one another by heat-distributing passages, that heat may be easily supplied to or shut off from any part of any of these chambers. A jacketing chamber is placed so as to extend above all three chambers, the burnt gases passing from this into the chimney.—A. G. L.

Alloys; Manufacture of metallic ——. A. Jacobsen, Hamburg, Germany. Eng. Pats. 19,198 and 19,198A, Sept. 22, 1905.

See Fr. Pat. 353,999 of 1905; this J., 1905, 1071.—T. F. B.

Metallic alloys; Manufacture of ——. A. Jacobsen, Hamburg, Germany. Eng. Pat. 19,198B, Sept. 22, 1905.

To 50 per cent. of the alloy described in Eng. Pat. 6945 of 1904 (this J., 1904, 1220), which consists of two atomic weights each of copper and iron, and one atomic weight each of nickel and aluminium, there is added 50 per cent. of copper. The new alloy is of the same strength as the former one, but is considerably softer, and more ductile. Useful results are also obtained if the proportion of copper be varied from 20 to 80 per cent.—A. G. L.

Aluminium alloys; Process for improving —— by heating and chilling. C. Claessen, Berlin. Eng. Pat. 19,282, Sept. 23, 1905.

See Fr. Pat. 358,028 of 1905 and Addition thereto; this J., 1906, 185 and 482.—T. F. B.

Metals; Refining ——, and apparatus therefor. W. S. Simpson, London. Eng. Pat. 19,781, Sept. 30, 1905.

See Fr. Pat. 360,408 of 1905; this J., 1906, 542.—T. F. B.

Crucibles or vessels for the mixing and alloyage of metals. W. S. Simpson, London. Eng. Pat. 19,781A, Sept. 30, 1905.

See Fr. Pat. 360,408 of 1905; this J., 1906, 542.—T. F. B.

Metals; Method of manufacturing —— according to the aluminothermic process. H. Goldschmidt and O. Weil, Essen on Ruhr, Germany. Eng. Pat. 20,004, Oct. 3, 1905.

See Fr. Pat. 358,071 of 1905; this J., 1906, 185.—T. F. B.

Ores and their by-products; Process for the sulphatisation of ——. E. Enke, Kattowitz, Germany. Eng. Pat. 22,900, Nov. 8, 1905.

See Ger. Pat. 163,410 of 1904; this J., 1906, 221.—T. F. B.

Ore concentration. H. L. Sulman, H. F. Kirkpatrick-Picard, and J. Ballot, London. Eng. Pat. 26,712, Dec. 21, 1905.

See Fr. Pat. 363,418 of 1906; this J., 1906, 890.—T. F. B.

Screen for washing ores, combustible minerals, and the like. C. J. A. Marty, Limoges, France. Eng. Pat. 11,764, May 19, 1906.

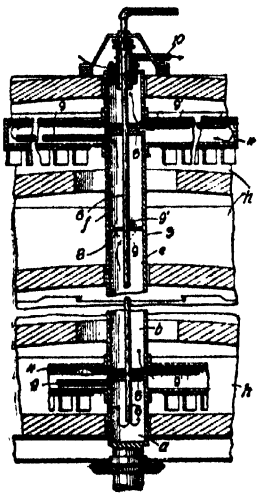
The screen consists essentially of two superimposed, perforated metal plates, between which solid or hollow balls act like valves above each hole in the lower plate. The lower plate is also provided with one or more additional openings corresponding to the same number of collectors below them, in which the small quantity of sand, &c., collects which might impede the action of the balls.—A. G. L.

Metals; Process and apparatus for obtaining —— from their sulphides. T. J. Heskett, Brunswick, Australia. Eng. Pat. 26,980, Dec. 27, 1905.

Impure sulphide ores are first smelted in a blast-furnace with sufficient fuel and fluxes to produce a pure sulphide, which flows in a continuous stream into an oxidising chamber. Pure sulphides may be directly charged into and melted in the latter through a hopper at the top. In the oxidising chamber, rapid oxidation is effected by an air-blast supplied through tuyères below the level of the molten sulphide. The volatilised metallic oxides, together with sulphur dioxide, pass into a reducing chamber supplied with solid or gaseous reducing agents, in which the metals are reduced, the less volatile metals collecting in the molten condition at the bottom of the reducing chamber. The more volatile metals are also reduced, but pass on to a condensing chamber, where they deposit in the order of their condensation. The sulphur dioxide passes on, and can be utilised as usual.—A. G. L.

Steel; Manufacture of —— in Martin furnaces. V. Defays, Brussels. Eng. Pat. 9996, April 28, 1906. Under Int. Conv., April 29, 1905.

See Fr. Pat. 365,671 of 1906; this J., 1906, 991.—T. F. B.



United States Patents.

Blast furnace. L. Heckscher, Radnor, Pa. U.S. Pat. 828,310, Aug. 14, 1906.

The object of the invention is to secure even cooling of the walls of a blast furnace. For this purpose the masonry of the upper part of the furnace is supported not on the main mantle itself, but on a false mantle placed at about the point where the walls of the furnace begin to slope inwards. The false mantle is supported on the main mantle by a number of radial vertical plates, each of which has an opening in its lower part to allow water to pass through it. The main mantle is placed in the usual position, a little above the bosh, and is supported in the usual way on columns; its outer edge is turned upward so that it forms an annular trough. A mantle-jacket surrounds the walls of the blast furnace between

the two mantles, and below the main mantle, ending just above the tuyères is an annular trough leading to the waste pipe. Below the main mantle is placed an annular flange, tapering downwards and surrounding the bosh, but leaving an opening between it and the mantle-jacket. This flange prevents the water leaving the mantle-jacket. Water is projected against the mantle-jacket between and below the mantles by means of two circular pipes. —A. G. L.

Furnace; Roasting ——. F. Klepetko, New York. U.S. Pat. 831,165, Sept. 18, 1906.

The furnace comprises a number of superposed hearths, *h*, a hollow shaft, 3, passing through the hearths, and hollow arms, 4, radiating from the shaft and extending into the hearths. The shaft is divided into compartments, *a*, *b*, *c*, *f*, by partitions, 8; from each compartment, on one side of the partition, a tube, 9, leads into the corresponding hollow arm, and on the other side of the partition a complementary tube, 9¹, leads from this arm into the opposite one. A limited quantity of a cooling medium is introduced into the lowest compartment through the tube, 6; this is vaporised by the heat of the furnace charge, and the vapour circulates through each compartment in the shaft in succession, following the path indicated by the arrows, and finally escaping at 10.—A. S.

Furnace; Roasting ——. F. Klepetko, New York. U.S. Pat. 831,166, Sept. 18, 1906.

The furnace comprises a number of superposed hearths, with a vertical hollow shaft passing up through them. Hollow arms radiate from the shaft, and extend into the hearths. A cooling medium enters through a feed-pipe passing longitudinally through and discharging into the lower end of the shaft. An outlet pipe for the cooling medium also extends through the shaft, and discharges at the top, and branch pipes lead from the interiors of the hollow arms to the outlet pipe.—A. S.

Furnace; Ore-roasting ——. W. A. Maddern, Boulder City, Western Australia. U.S. Pat. 831,232, Sept. 18, 1906.

See Eng. Pat. 24,124 of 1902; this J., 1904, 22.—T. F. B.

Furnace; Ore-roasting ——. T. Edwards, Ballarat, Victoria. U.S. Pat. 832,248, Oct. 2, 1906.

See Eng. Pat. 28,464 of 1903; this J., 1904, 1150.—T. F. B.

Furnace for calcining or burning briquettes of ore. F. J. Bergendal, Herräng, Sweden. U.S. Pat. 832,358, Oct. 2, 1906.

See Eng. Pat. 9206 of 1905; this J., 1905, 958.—T. F. B.

Metal-bearing materials; Method of reducing ——. A. H. Helander, Pueblo, Colo. U.S. Pat. 831,067, Sept. 18, 1906.

To reduce metal-bearing materials, they are formed with fuel-bearing and fluxing materials into a viscous mixture, which is injected into a blast-furnace at the zone of fusion.—E. S.

Detinning [tin-plate]; Process of ——. K. Goldschmidt and J. Weber, Assignors to Th. Goldschmidt, Essen on Ruhr, Germany. U.S. Pat. 831,223, Sept. 18, 1906.

See Fr. Pat. 356,228 of 1905; this J., 1905, 1311.—T. F. B.

Ore separator and classifier. E. J. Swyny, Balmain, and S. G. Plucknett, Newtown, N.S.W. U.S. Pat. 831,252, Sept. 18, 1906.

See Eng. Pat. 19,140 of 1904; this J., 1904, 1150.—T. F.B.

Vanadium ores; Treating ——. J. O. Handy, Pittsburg, Pa. U.S. Pat. 831,280, Sept. 18, 1906.

The ore is mixed with a quantity of sodium salt (sodium chloride), sufficient to form sodium pyrovanadate with the vanadium present, and heated to distil off sulphur. Residual sulphur is removed by roasting, the product is extracted with hot water, and the solution evaporated to dryness. The residue is purified by washing it with cold water, dissolving in hot water, acidulating, and evaporating to dryness, and again washing with cold water. —A. G. L.

Alloy for bearings. H. Kreusler, Wilmersdorf, Assignor to Siemens und Halske A.-G., Berlin. U.S. Pat. 831,357, Sept. 18, 1906.

See Eng. Pat. 10,513 of 1906; this J., 1906, 816.—T. F. B.

Ferrophosphorus; Manufacture of ——. J. J. Gray, jun., Rochdale, Tenn. U.S. Pat. 831,427, Sept. 18, 1906.

A mixture containing iron ore, phosphate rock, and a silicious material in such proportions as may be required to liberate the amount of phosphorus it is desired to combine with the iron, is charged into a blast furnace and smelted.—E. S.

Armour plates; Manufacture of ——. R. A. Hadfield, Sheffield. U.S. Pat. 831,858, Sept. 25, 1906.

See Eng. Pat. 15,220 of 1904; this J., 1905, 736.—T. F. B.

Steel; Art of hardening and toughening ——. J. Churchward, New York. U.S. Pat. 832,770, Oct. 9, 1906.

The process is the same as that described in Eng. Pat. 15,423 of 1905 (this J., 1906, 889), except that tungsten is added to the steel as well as chromium, nickel, and manganese.—A. S.

Metals; Art of hardening and toughening ——. J. Churchward, New York. U.S. Pat. 832,772, Oct. 9, 1906.

Vanadium is added to the steel in addition to the metals mentioned in U.S. Pat. 832,770 (see preceding abstract). —A. S.

Alloy of iron and steel; Self-hardening ——. J. Churchward, New York. U.S. Pat. 832,773, Oct. 9, 1906.

Claim is made for a steel containing: carbon, about 0·20 to 0·60 per cent; nickel, 4 to 6 per cent.; tungsten, 0·5 to 1·5 per cent.; chromium, 2·5 to 3 per cent.; manganese, 0·5 to 1 per cent., and vanadium, 0·25 to 0·5 per cent.—A. S.

Iron and steel; Method of recovering —— from slags. R. Baggaley, Pittsburg, Pa. U.S. Pat. 832,948, Oct. 9, 1906.

Iron is obtained from the ferruginous slag of a copper furnace by mixing the slag with carbonaceous fuel and a flux, and subjecting it to a temperature higher than that ordinarily used in an iron blast-furnace. The iron produced is then bessemerised.—A. G. L.

[*Copper*] *Slimes; Process of treating* ——. H. N. Thomson and F. Laist, Anaconda, Mont. U.S. Pat. 832,176, Oct. 2, 1906.

Slimes from metallic (copper) ores are dried and disintegrated, and then roasted at a dull red heat. The roasted product is then treated with a mixture of sulphuric acid, iron sulphate, and sodium chloride, gases from a roasting-furnace containing air and sulphur dioxide being at the same time passed through the mass. The solution obtained is filtered, the tailings are washed, and hydrogen sulphide is passed through the combined filtrate and washings. The metallic (copper) sulphide is finally smelted to metal (copper) as usual.—A. G. L.

Converting mattes and speisses and other metallic compounds; Apparatus for ——. H. Haas, San Francisco, Cal. U.S. Pat. 832,665, Oct. 9, 1906.

In the lining of the converter a series of conduits is arranged about a central axis, these conduits all having an upward, outward, and forward inclination, whereby the blasts of air which are forced through them tend to rotate the mass in the converter in the same direction.—A. S.

Copper matte; Process of smelting ——. W. Kemp, Tucson, Arizona, Assignor to the Kemp Hydro-Carbon Furnace Co., New York. U.S. Pat. 832,738, Oct. 9, 1906.

Copper matte, mixed with silica or other flux, or alone, is charged into a furnace in the solid state, and reduced to metallic copper by subjecting it to the action of a burning mixture of oil-vapour, steam, and air, containing an excess of oxygen, the lower zones of the charge being successively reduced.—A. G. L.

Ore roasting and oxidising apparatus. F. C. Butterfield, Oakland, Cal. U.S. Pat. 832,292, Oct. 2, 1906.

The furnace consists of a horizontally rotating shell having heads with openings aligned around the circumferences of the heads, for the admission of ore at one end and the discharge of solid residue at the other. The openings are controlled by sliding gates. Reduced tubular ends project centrally from the heads. A combustion chamber is provided, movable to and fro from the inlet of the shell, and abutting endwise against the inlet, for the liquid-fuel supply. The tubular extension at the opposite end of the furnace is connected to settling and condensing chambers for the delivery of the separated gases and vapours.—A. G. L.

Ores; Process of treating complex sulphide ——. W. G. Rumbald and G. Patchin, London. U.S. Pat. 832,341, Oct. 2, 1906.

See Eng. Pat. 2532 of 1905; this J., 1906, 325.—T. F. B.

Metals; Process of separating —— *from their ores.* G. H. Waterbury., Assignor to J. J. Huddart, Denver, Colo. U.S. Pat. 832,563, Oct. 2, 1906.

The powdered ore is treated with a solution in water of salt, alkali nitrate, and sulphur dioxide, the whole being agitated and heated by the simultaneous introduction of air and steam. The solution obtained is drawn off, and the metals in it are precipitated by hydrogen sulphide, forced into the liquid by air under pressure.—A. G. L.

Metal values; Method of extracting —— *from ores.* R. Baggaley, Pittsburg, Pa. U.S. Pat. 832,833, Oct. 9, 1906.

Ores are "liquated" without the use of carbonaceous fuel by feeding preheated silicious ores into a bath of low-grade matte at one end in a converting furnace, the bath being kept hot, and its contents well mixed by blowing air through it. The silicious ore fed in is in excess of the amount that can be melted through the formation of selective slags. Molten slag, matte, and "silicious liquated matter" overflow continuously into a forehearth at a lower level for separation by gravity.—A. G. L.

[*Gold, silver, and copper*]. *Metals; Art of precipitating* —— *from cyanide solutions.* W. J. Sharwood, Berkeley, Cal., Assignor to C. W. Merrill, Lead, S.D. U.S. Pat. 832,860, Oct. 9, 1906.

Copper and the precious metals are precipitated from alkaline cyanide solutions by neutralising the solutions with the proper quantity of acid material, and then bringing them into contact with metallic zinc or an alloy of zinc in a finely-divided state.—A. G. L.

Briquettes of ore, &c.; Process of manufacturing ——. H. Schulte-Steinberg, Düren, Germany. U.S. Pat. 833,005, Oct. 9, 1906.

See Eng. Pat. 3235 of 1904; this J., 1904, 444.—T. F. B.

French Patents.

Cementation of objects of iron or steel; Process and apparatus for the ——. A. W. Machlet. Fr. Pat. 366,245, May 15, 1906.

The invention is especially applicable to the cementation of a number of small objects at the same time. The objects are heated in a large crucible to a temperature exceeding a red heat, but below their fusing point, the temperature being kept very even and uniform. An atmosphere of carbonaceous gas is kept in the crucible during the heating, and the articles are moved about by rotating the crucible. The articles are also surrounded by a reducing atmosphere during the cooling. After several heatings and coolings, the articles are tempered as usual by quenching. The apparatus used in carrying out the above process is also claimed.—A. G. L.

Retort, muffle, crucible, &c., for the reduction of zinc ores and other purposes. D. Delville and Comp. des Métaux et Prod. Chim. D'Overpelt. Fr. Pat. 366,380, May 18, 1906.

The retort, &c., is provided on the outside with a number of horizontal channels for the better utilisation and transmission of the heat supplied. The channels are of such form that a section of the retort appears much like a cog wheel.—A. G. L.

Bismuth; Process for the extraction of ——. H. Becker, Fr. Pat. 366,439, May 21, 1906.

The bismuth is extracted from its ores and compounds by a solution of an alkali hyposulphite or an alkaline-earth hyposulphite, and then precipitated as bismuth sulphide by the addition of an alkali (or alkaline-earth) sulphide, the solution being at the same time regenerated. Or, the bismuth is extracted by a solution of a "per-salt," preferably ferric chloride or sulphate, to which also other salts may be added, and is precipitated from the solution, either as basic salt by heating or diluting the solution, or as metal, by the action of another metal, such as zinc, or by electrolysis preferably with the aid of a diaphragm, the electrolysis also regenerating the solution which, in the other cases, must be regenerated by blowing air or chlorine through it. If other metals, *e.g.*, copper, which would render the bismuth obtained impure, are present in the ore, they may be removed by a preliminary treatment; *e.g.*, in the case of copper, the ore might be extracted with ammonia or dilute hydrochloric acid.—A. G. L.

Armour plates; Process of making ——. Marrel Frères. Fr. Pat. 366,532, May 23, 1906.

The armour plates are made from a crucible steel containing 0·160 to 0·300 per cent. of carbon, 0·4 to 0·8 per cent. of chromium, and 3 to 4 per cent. of nickel; the chromium may be wholly or partly replaced by titanium, tungsten, molybdenum, or vanadium. The steel, after rolling once, is, if desired, subjected to the cementation process; it is then heated to a determined temperature, and cooled in such a manner as to give the desired structure, the operations being repeated until this is attained. Both the faces are then tempered at the same time, by heating the whole plate very gently and evenly, and quenching on both sides. The structure of the steel obtained should show an amorphous grain, and be porcelain-like in the cemented portions.—A. G. L.

Ores; Process for the dry concentration of ——. Minerals Separation Ltd. Fr. Pat. 366,685, May 29, 1906.

The process for the dry concentration of ores comprises the use of a concentrating table provided with longitudinal ribs or corrugations between which are passages for a current of air. The ribs or corrugations are of truncated conical form in cross-section. The top or cover of the table, on to which the ore is fed, is of cloth or other material permeable to air. The table is inclined, both longitudinally and transversely, and a longitudinal reciprocating motion is imparted to it. The ore is fed on to the upper end of the table, and by the motion of the table and the action of the air, which is introduced below and rises through the passages between the corrugations, is separated into layers of different density, as it travels towards the lower end of the table.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 994.)

(*A.*)—ELECTRO-CHEMISTRY.

Nickel salts; Periodic phenomena during the electrolysis of ——. A. Thiel and A. Windelschmidt. Z. Elektrochem., 1906, 12, 737.

The formation of nickel peroxide at the anode, which is noted in the electrolysis of nickel salts in ammoniacal or oxalic acid solutions is followed by a re-dissolving of the deposit. The formation and disappearance of the peroxide occur periodically. This is clearly observed by the deflections of the ammeter and voltmeter. The potential difference between the electrodes increases with the formation of the deposit, and falls with its re-dissolving. In ammoniacal solutions the periodic deflections are first observed when almost all the nickel has been deposited; they cease so soon as the metal is completely removed from the electrolyte. In oxalate solutions the phenomena are still more marked, and commence at an earlier stage.
—R. S. H.

English Patents.

Batteries; Primary ——. C. Ruzicka, London. Eng. Pat. 18,931, Sept. 19, 1905.

The battery comprises a hermetically-sealed vessel containing electrodes consisting of frames, perforated plates, or gauze sheets, composed of two different metals, or of a metal and a metallic carbide, or of a metallic carbide and carbon, wholly or partially coated, or charged, with like substances of an electro-conductive character, or capable of being rendered electro-conductive. The electrolyte may consist of chlorine, fluorine, oxygen, nitrogen, or hydrogen, under sufficient pressure to maintain it, or a portion of it, in the liquid state, or it may consist of water, or other suitable liquid, having in solution salts of metals, the oxides of which are strongly caustic, the liquid being charged with chlorine, or other suitable gas, under a pressure above that of the atmosphere.—B. N.

Wood; Treatment of —— to be used in electro-chemical apparatus. D. H. Whitehead and Q. Marino, London. Eng. Pat. 20,143, Oct. 5, 1905.

Wood, to be used for the construction of the diaphragms or cells of electric batteries or accumulators, in the form of plates, tubes, or the like, is submitted to the influence of an "ammoniacal-cupreous" liquor, and afterwards to a bath of "liquid ammonia" (sp. gr. 0·88). The wood is then withdrawn, well washed in water, and immersed in nitric acid, after which it is submitted to the action of sulphurous acid. Finally it is immersed in a solution composed of alcohol, caustic potash, and ethyl acetate in various proportions. The wood is thus rendered porous and permeable to the electric current, whilst remaining neutral to the electro-chemical reactions. A modification is described in which, at the end of the above processes, a bath of ammonia solution is employed, in order to render neutral the wood impregnated with the "sulpho-nitric" liquid.—B. N.

Mercury electrolytes for electrolytic cells. H. S. Hatfield and The Reason Manufacturing Co., Ltd., Brighton. Eng. Pat. 20,500, Oct. 10, 1905.

The electrolyte, for use in electrolytic electricity meters, consists of a solution of a double salt, or two or more salts such as mercuric iodide and potassium iodide.
—B. N.

Furnaces; Electric —— for treating gases. H. Pauling, Gelsenkirchen IV., Westphalia. Eng. Pat. 8452, April 9, 1906.

The gas is subjected to the action of electrical discharges between a pair of diverging electrodes, the gas being separated into two currents of different velocities which are passed between the opposite ends of the electrodes. One current of gas serves to convey the electric discharges from the place where they are formed, thus preventing short-circuiting, whilst the other current causes the discharges, thus conveyed, to continue their propagation along the electrodes, so as to form arcs of the desired great lengths.
—B. N.

Emulsions of mercury or other conducting substances; Process and apparatus for making ——. E. Lederer, Vienna. Eng. Pat. 18,513, Sept. 13, 1905.

For obtaining very fine emulsions of metals for making salves, &c., a continuous electrical sparking is brought about between two electrodes, whereby the cathode metal in thrown off in a fine state of division. The disintegration is brought about in media such as vaseline, tallow, or lanolin, which during the process are in the molten condition but subsequently become hard or set. The electrodes are caused to come together and are separated by the action of the electric current, which traverses a solenoid, within which is an iron core attached to one of the electrodes. Several forms of construction are described.—R. S. H.

Chromic acid; Electrolytic production of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 27,009, Dec. 27, 1905.

This invention relates to a process of manufacturing chromic acid by electrolytically oxidising a chromium compound of a lower degree of oxidation in an acid solution. A cell is employed in which the cathode and anode are separated from each other by a wall, which does not reach to the bottom of the cell, the solution to be electrolysed being supplied in such a manner that the inner or cathode compartment always contains a sufficient quantity of the acid to allow the electrolysis to proceed properly. The solution is preferably introduced, either continuously or intermittently, as a layer near to the bottom of the cell, so that it approaches the anode at the points of greatest current density, and afterwards passes to the points of lower current density. Two examples of results are given, with the proportions of substances used, in one of which 83 per cent. of the chromium was oxidised, 87·5 per cent. of the current supplied being utilised, and in the other, 84 to 90 per cent. of the chromium was oxidised, 78 per cent. of the current being utilised.—B. N.

Hypochlorite solutions; [Electrolytic] Manufacture of ——. W. P. Digby and A. W. M. Marshall, London. Eng. Pat. 915, Jan. 12, 1906.

In the production of hypochlorites by the electrolysis of saline solutions, a diaphragm of ebonite, slate, or other suitable non-porous material is interposed between the anode and cathode. The diaphragm is provided with a number of small perforations in the portion below the liquid level. By having a higher level of liquid in the cathode chamber or by other means, the electrolyte is caused to pass through the perforations, and impinge upon the anode surface.—R. S. H.

Alkaline chloride solutions; Apparatus for the electrolytic decomposition of —— by means of mercury cathodes. J. J. Rink, Copenhagen. Eng. Pat. 10,219, May 1, 1906.

See Fr. Pat. 365,838 of 1906; following these.—T. F. B.

UNITED STATES PATENTS.

Insulating material and process of manufacturing same. J. Billwiller, Goldach, Switzerland. U.S. Pat. 831,321, Sept. 18, 1906.

See Fr. Pat. 349,850 of 1904; this J., 1905, 739.—T. F. B.

Furnace; Electric ——. E. A. Storey, Newark, N.J. U.S. Pat. 832,511, Oct. 2, 1906.

This invention relates to an electric or dielectric furnace, and comprises a furnace proper, with conductors arranged horizontally and extending through opposite walls of the furnace, and a "resistor" supported by the inner ends of the conductors. Other conductors, supported by the furnace and movable vertically, are arranged to make contact with the "resistor," all the conductors being freely movable into and out of operative position. Tracks are supported within the furnace, and a wagon moves on these, means being provided for moving the wagon lengthwise of the furnace.—B. N.

Air or other gases; Electrically treating ——. J. H. Bridge, Philadelphia, Pa. U.S. Pat. 832,767, Oct. 9, 1906.

This invention relates to a method of electrically treating air or other gas by the silent discharge, a number of annular electric discharges, surrounding a corresponding number of air spaces, being formed on the surface of a perforated electrode. Air is passed, from the under side of the electrode, through the perforations, in minute streams into the interior of the air spaces. Each stream of air, emerging from the perforations, is continued in the form of an outward jet from the surface of the electrode, whilst simultaneously the electric discharge is caused to assume an elongated shape in the same plane as the air current, and substantially surrounding it. The jet of air is then caused to break through the luminous walls of the discharge, thus securing actual contact with it. The streams of air are finally re-united, and led in bulk away from the action of the electric discharges.—B. N.

Electrifier for treating air or other gas. J. H. Bridge, Philadelphia, Pa. U.S. Pat. 832,768, Oct. 9, 1906.

The electrifier comprises solid and perforated tubular electrodes concentrically arranged with respect to each other, with an insulating means adapted to close the electrodes at one end, and form in conjunction with the electrodes an inlet and outlet for the air to be treated. Each electrode is provided with a conductor; a fuse and disc forming part of the conductor for the positive electrode. The disc is so arranged that, when the fuse is destroyed by an excessive electric current passing through, it closes the inlet for air leading to the electrodes.—B. N.

Electrode for use in the manufacture of bleaching liquor. R. Kother, Cunewalde, Germany, Assignor to C.E. Waithman, Gaddum, Cheshire. U.S. Pat. 832,983, Oct. 9, 1906.

See Eng. Pat. 21,437 of 1905; this J., 1906, 379.—T. F. B.

FRENCH PATENTS.

Voltaic arcs of great size; Production of ——. Badische Anilin und Soda Fabrik. Second Addition, dated April 26, 1906 (under Int. Conv., Feb. 26 and 27, 1906), to Fr. Pat. 357,358, Aug. 30, 1905.

By using several reaction tubes and polyphase currents, the arcs may be directly connected without the use of a counter-electrode. Several insulated electrodes may be mounted in the interior of each tube.—B. N.

Electrodes and filaments of pure graphite for electric lamps. M. Cresta. Fr. Pat. 366,142, May 12, 1906. II., page 1035.

Incandescence electric lamps; Process of making conductive connections, of metallic character, between the filaments and current leads of ——. H. Kusel. Fr. Pat. 366,267, May 16, 1906. II., page 1035.

Salts of the oxyhalogen acids; Electrolytic production of ——. Deutsche Solvay-Werke A.-G. Second Addition, dated April 20, 1906, to Fr. Pat. 362,737, Jan. 10, 1906. (See also this J., 1906, 766 and 891.)

In the electrolysis of the halogen salts of the alkali and alkaline-earth metals in cells without diaphragms with a view to producing salts of the oxyhalogen acids, soluble compounds of lead, copper, antimony, or selenium are added to the electrolyte. These additions limit considerably the wasteful cathodic reduction.—R. S. H.

Electrolysis of solutions of alkali chlorides, with mercury cathode; Apparatus for the ——. J. J. Rink. Fr. Pat. 365,838, May 2, 1906.

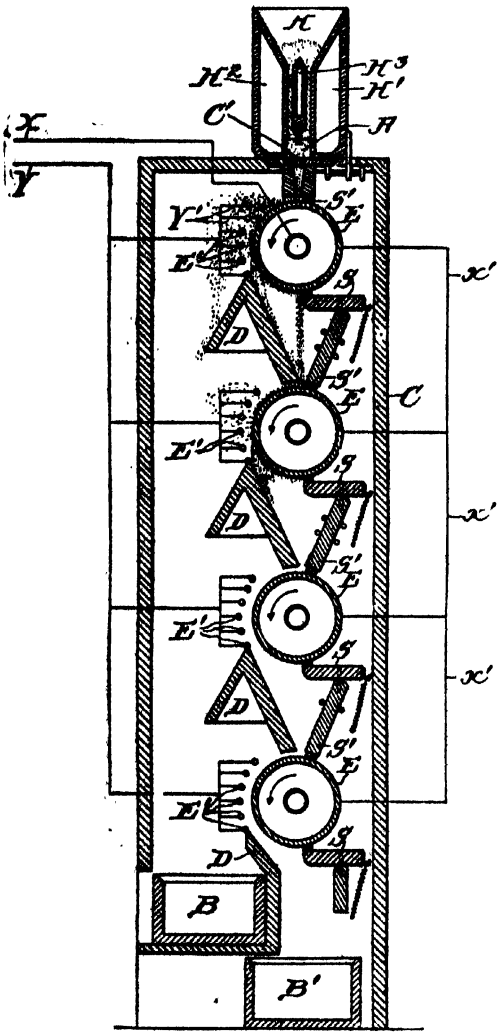
A diaphragm of asbestos or other suitable material separates the cell into two chambers, each of which is provided with a circulation system for the solution of the alkali chloride. In this manner the salt solution in proximity to the mercury cathode is exempt from dissolved chlorine. The amalgam is decomposed in a separate chamber, where it falls in a thin stream over suspended sheets of metal.—R. S. H.

Fertiliser; Highly nitrogenous product specially suitable as a ——, and process of making the same. Soc. d'Electro-Chimie. Fr. Pat. 366,376, May 18, 1906. XV., page 1059.

[*Electrical*] *Fusion of corrosive or non-corrosive substances* [*Sodium peroxide*]. The Roessler and Hasslacher Chemical Co. Fr. Pat. 366,523, May 23, 1906.

The material to be fused is contained in a vessel the walls of which are cooled by water, and thus remain coated with a protective layer of unfused material. Electrodes of sheet copper or other metal are supported inside the vessel at some distance from the walls, and are connected to a source of alternating current, which can be regulated to the desired intensity. For the commencement of the operation the two electrodes are short-circuited by a resistance; but so soon as a mass of the fused material fills the space between the electrodes, the process can be carried on continuously, fresh quantities of the substance being fed in at the surface, and the fused product being allowed to flow out of the vessel in corresponding amount. The operation is described in its application to the fusion of sodium peroxide. The current density in this case should range between 235 and 390 amperes per sq. dm. of the submerged electrodes. Provided the current is not interrupted, and the water cooling of the vessel is maintained, the sodium peroxide is undecomposed, and the vessel and electrodes are not attacked.—R. S. H.

(*B.*)—ELECTRO-METALLURGY.



Fused electrolytes; Factory scale experiments with —— Part III. E. A. Ashcroft. Electrochem. and Met. Ind., 1906, 4, 357—358. (See also this J., 1906, 594.)

The author describes several possible applications of his electrolytic apparatus with two chambers, and magnetic stirring and circulation of the intermediate electrode. In the treatment of mixed ores, it is proposed to electrolyse the sulphide ore directly, all the metals being deposited on to the fluid lead cathode by the aid of a high current density, the sulphur distilling off and being collected. In the second compartment, the metals are dissolved at the anode, and are received fractionally upon a suitable cathode. A special form of magnetically rotating disc is described, which would be applicable as a cathode for such purposes. The molten metals separating on these discs are collected after being thrown off from the periphery or by the centrifugal action are forced inwards along spiral grooves towards the centre. In the case of solid metals, the condition of the deposit is improved by the friction with the molten electrolyte resulting from the rotation of the disc.—R. S. H.

UNITED STATES PATENTS.

Electrostatic separation; Method of and apparatus for ——. C. W. Pickard, Amesbury, Mass., Assignor to Huff Electrostatic Separator Co., Maine. U.S. Pats. 827,115 and 827,116, July 31, 1906.

THE patents relate to a process and apparatus for electrostatically separating or concentrating mixed comminuted materials. The apparatus consists of a casing, C, in which hollow, cylindrical, metallic electrodes, E, are mounted one above the other on hollow trunnions. These electrodes rotate in the direction indicated by the arrows, and are connected by the wires, X, x^1, to one pole of a source of, electricity (preferably that described in U.S. Pat. 796,011 of 1905), of which the other pole is connected by the wires, Y, Y^1, to the electrodes, E^1, of fine metal wires enclosed in relatively thick glass tubes. The feed-hopper, H, is provided with heating chambers, H^1, H^2, and H^3, into which hot gases are passed. Hot gases are also passed through the electrodes, E. The ore is fed from the hopper, by means of an agitator disposed at A, through the slot, C^1, on to the upper electrode, E, and then falls in succession on to the other electrodes. The attracted particles collect in the bin, B^1, and the repelled particles in B, the two streams of falling material being separated by the dividing plates, D. Any material adhering to the rotating electrodes is removed by the scrapers, S, S^1.—A. S.

Zinc; Process for the electrolytic production of ——. V. Engelhardt, Vienna, Assignor to Siemens und Halske A.-G., Berlin. U.S. Pat. 831,843, Sept. 25, 1906.

SEE Eng. Pat. 16,396 of 1904; this J., 1904, 1098.—T. F. B.

FRENCH PATENTS.

Electric induction furnace for high frequency currents. Schneider et Cie. Fr. Pat. 361,627, July 13, 1905.

THE furnace consists of a chamber or crucible of refractory material, which contains the metal to be treated. The outer wall of the furnace is bound and supported by a solenoid of copper or other metal through which a high frequency alternating current is passed. The solenoid may consist of a number of separate, broken, and insulated coils, which are connected electrically in series.—R. S. H.

Induction furnace for continuous fusion. A. Hiorth. Fr. Pat. 365,655, April 23, 1906. Under Int. Conv., Jan. 4, 1906.

IN electric furnaces of the induction type, a common primary coil is employed for two or more furnaces. The iron core is constructed so as to be detachable in sections, and it is arranged so that it can serve alternatively or simultaneously for two or more furnaces. The chief object of the invention is to ensure the continuity of the production, and avoid delays caused by the relining of the furnaces which require a slow and lengthy drying.—R. S. H.

Electric [Induction] furnace. Röchling'sche Eisen und Stahlwerke G. m. b. H. and W. Rodenhauser. Fr. Pat. 366,440, May 21, 1906.

THE furnace, which is intended for the production of steel by the refining of pig-iron, or for other metallurgical purposes, is characterised by the fact that the primary coils serve for inducing current in two or more separate secondary circuits. In the first place, a secondary is formed by the charge of metal contained in an annular channel surrounding the primary. This annular channel is widened out at the sides of the furnace so as to form chambers containing a considerable mass of the charge. An auxiliary secondary circuit is formed of copper coils, wound over or between the primary windings, these coils being connected to conducting blocks or electrodes placed at the sides of the furnace and in contact with the charge. The currents in the two secondary circuits thus superimpose their effects in heating the charge in the furnace. It is proposed to construct the secondary coils of copper tubes through which a water circulation is kept up, and thus utilise them for protecting the walls of the furnace and the primary coils from excessive heating.—R. S. H.

Electro-deposition of metal upon metal plates. Hille und Müller. Fr. Pat. 365,456, April 20, 1906. Under Int. Conv., April 22, 1905.

THE metal plates or sheets, upon which it is desired to deposit a film of metal electrolytically, are joined together to form a continuous band, which is transported through the various vats in a similar manner to an ordinary straight band of metal.—R. S. H.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 996.)

Castor oil; Caucasian ——. O. Liebreich. Therap. Monats., 1906, 20, 444.

A SPECIMEN of expressed castor oil, from the Caucasus, which had been kept by the author for eight years gave the usual characteristic numbers. When 8 c.c. were shaken with 3 c.c. of carbon bisulphide and 1 c.c. of strong

sulphuric acid, a brown-orange colour was produced. Under similar conditions the best Italian castor oil gave a yellow-red colour-reaction. The latter had a higher free acid value, 7·3; the acid value of fresh oil, extracted from Caucasian seeds with ether, was only 2·6.—J. O. B.

Oleic acid; Constitution of ——, *and action of ozone on oils and fats.* E. Molinari and E. Soncini. Ber., 1906, **39**, 2735—2744.

Ozone value of oils.—The saturated fatty acids of linseed oil were found to absorb no ozone, whilst the unsaturated fatty acids took it up quantitatively. A good solvent to prevent the substance becoming viscid under the action of the gas was found in hexane, which could be easily expelled, after the reaction, by means of a current of ozone. The authors determined the ozone values of various oils (maize, castor, rape, &c.), and found that the increase of weight corresponded with the amount calculated from the iodine value. Thus, linseed oil with an iodine value of 171 absorbed 30 per cent. of ozone, as against the theoretical 32·3 per cent.

New method of determining ozone.—Ordinary olein was used as the absorbing agent, and it was found that the increase in weight corresponded with the amount of ozone absorbed.

Action of ozone on oleic acid.—Oleic acid prepared by the authors was purified, and gave a product with the correct elementary composition, and an iodine value of 90·03. On treating a solution of 10 grms. of this acid in glacial acetic acid with ozone, the increase in weight was 1·70 grms., showing that 1 mol. of oleic acid had absorbed 1 mol. of ozone (O_3). The oleic acid ozonide produced was a viscous, almost colourless, transparent liquid, heavier than water, and absorbing no iodine. It was stable up to 80° or 90° C., but decomposed on raising the temperature. Its elementary composition and molecular weight corresponded with the formula $C_{18}H_{34}O_5$. It had only a slight reducing action on Fehling's solution. No salts could be prepared owing to the readiness with which it decomposed by water in the presence of alkalis. When decomposed by dry or moist heat, it yielded five products—a mobile liquid (b.pt. about 190° C.) with a pungent pleasant odour, and four fatty acids, *viz.*, azelaic acid, normal nonylic acid, and two others separable by distillation *in vacuo*. From a study of these decomposition products, and the mode of their formation, the authors came to the conclusion that the double bond of oleic acid must be in the middle of the normal chain between C_9 and C_{10}, and that the following equation represented the formation of the ozonide:—

$$CH_3(CH_2)_7.CH:CH.(CH_2)_7.COOH + O_3 = CH_3(CH_2)_7.CH.CH.(CH_2)_7COOH$$
$$\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad O.O.O.$$

The authors consider that their results prove conclusively that oleic acid absorbs three atoms of oxygen and not four as found by Harries (Ber., 1905, 1630).—C. A. M.

Oleic acid; Ozonides of ——. C. Harries and C. Thieme. Ber., 1906, **39**, 2844—2846.

In a previous communication (Annalen, 1906, **343**, 318), the authors showed that on treating a solution of oleic acid in chloroform with ozone, a thick syrup was produced, and the addition compound was found to have absorbed 4 atoms of oxygen. They now find that if this substance be washed with water containing sodium bicarbonate, dried, and extracted with ether, the new product is a liquid containing only 3 atoms of absorbed oxygen. Hence they term their former product oleic acid perozonide, and the new one normal oleic acid ozonide. The perozonide obtained quantitatively by their former method can be purified by being dissolved in ethyl acetate and precipitated by petroleum spirit. It is a colourless, almost glass-like product, which gradually breaks up on contact with water, yielding a deposit of azelaic acid. The normal ozonide is a colourless viscous oil, which is also slowly decomposed by water yielding varying amounts of azelaic acid. The two ozonides differ mainly in regard to their behaviour with water, the perozonide giving a far more pronounced reaction for hydrogen peroxide than does the normal ozonide. The decomposition products of both with water are qualitatively identical, *viz.*, azelaic and nonylic acids or their aldehydes. The constitutional formula given for the normal ozonide is the same as that given by Molinari and Soncini (see preceding abstract).—C. A. M.

Butter; Detection of cocoanut oil and margarine in ——. L. Robin. Compt. rend., 1906, **143**, 512—514.

The fatty acids obtained from cocoanut oil are almost entirely soluble in 60 per cent.. alcohol, at a temperature of 15° C., whilst the fatty acids of pure butter are only partially soluble, and those of margarine very slightly soluble. It is well known that the proportion of the fatty acids which are soluble in water, is greater in the case of butter than in the case of cocoanut oil and margarine, and that cocoanut oil yields a far larger quantity of fatty acids soluble in 60 per cent. alcohol, but insoluble in water, than do butter and margarine. On these facts the author bases a method for the detection of cocoanut oil or margarine, or mixtures of the same, in butter. The details of the process are as follows:—Five grms. of the sample are placed in a graduated 150 c.c. flask, 25 c.c. of alcoholic potassium hydroxide solution are added, the flask is attached to a reflux condenser, and the contents gently boiled for five minutes, to saponify the fat. After the solution has cooled a little, water is added to bring the percentage of alcohol in the mixture to about 56·5. Sufficient N/2 alcoholic hydrochloric acid is now added to neutralise the excess of potassium hydroxide exactly, and liberate the fatty acids from the soap. The hydrochloric acid is prepared by mixing the requisite amount of acid with alcohol, diluting with water until the solution contains 56·5 per cent. of alcohol, and then adding 56·5 per cent. alcohol to make the solution half normal. The quantity of acid to be added to the soap solution is ascertained by titrating a separate quantity of 25 c.c. of the potassium hydroxide solution with the acid. The contents of the flask are now cooled to 15° C., made up to 150 c.c. with 56·5 per cent. alcohol, mixed, and filtered. Fifty c.c. of the filtrate are titrated with N/10 alkali, using phenolphthalein as indicator. The result, expressed in c.c. of N/10 alkali per 1 grm. of fat, represents *the fatty acids soluble in 56·5 per cent. alcohol.* Another 50 c.c. of the filtrate are evaporated to a volume of 15 c.c., the separated fatty acids are collected on a wet filter, washed four times with cold water, then dissolved in alcohol, and the solution titrated. The result expresses *the fatty acids insoluble in water, but soluble in 56·5 per cent. alcohol.* The difference between the above two results gives *the fatty acids soluble in water.* The following figures were obtained as the results of a large number of experiments:—

	Soluble in alcohol.	Insoluble in water. (a).	Soluble in water. (b)	Ratio: $\frac{(a)}{(b)} \times 10$
Pure butter, maximum	14·82	2·31	6·66	12·7
Do. do. minimum	11·67	5·51	5·92	9·3
Margarine	2·67	2·56	0·11	232·7
Cocoanut oil	46·69	44·71	1·98	225·9

Analyses of mixtures containing from 5 to 14 per cent. of cocoanut oil or margarine, gave results which show that the method is capable of detecting this kind of adulteration. The figures given above do not represent the exact measure of the quantities of the various fatty acids in the fractions, as no account was taken of the fatty acids which were insoluble in 56·5 per cent. alcohol, their volume being ignored in making up the total volume to 150 c.c. This is, however, of no importance if the conditions as above laid down, be followed.—W. P. S.

Arachis oil-cake; Poisonous action of ——. E. Krüger. XVIIIA., page 1062.

ENGLISH PATENT.

Filtering apparatus more particularly adapted for the extraction of stearine from fatty acids in sulpho-oleic acid solution. M. Lanza, Turin, Italy. Eng. Pat. 11,877, May 21, 1906.

SEE Fr. Pat. 366,457 of 1906; following these.—T. F. B.

UNITED STATES PATENT.

Soap-drying machine. F. H. Merrill, Los Angeles, Cal. U.S. Pat. 831,884, Sept. 25, 1906.

THE soap is discharged by means of an elevator into a bin provided with a series of deflectors, sloping downwards, and having an air space between each. Or there may be a combination of two such bins, with the deflectors on their inner and outer walls. A deflector at the top directs the soap into either bin, and there is an air chamber below the partition between the bins, and a deflector for directing the air upwards from this chamber to either side of the partition. The soap is divided in a machine before reaching the elevator, and is distributed by means of spreaders before entering the bins.—C. A. M.

FRENCH PATENTS.

Filter particularly suitable for the separation of solid fatty acids from sulpholeic acid. M. Lanza. Fr. Pat. 366,457, May 21, 1906.

CLAIM is made for a filter specially suitable for the separation of solid particles in an emulsion. The lower part of the filtering material is in communication with an air-pump which produces alternate aspiration and compression, with the result that the fine particles which tend to clog the interstices are detached, clearing a passage for the liquid. For the separation of sulphonated fatty acids, the filter cloth is first covered with a fine layer of fatty acids which are washed several times at 25° C. with water acidified with sulphuric acid and containing a little sulpholeic acid.—C. A. M.

Oils and fats; Process of bleaching ——. H. A. Metz and P. S. Clarkson. Fr. Pat. 366,630, May 28, 1906.

TWO hundred parts of oil, such as maize oil, are agitated in a closed vessel for 10 hours with 600 parts of water and 15 parts of sodium hyposulphite (hydrosulphite). The mixture is then allowed to stand for about 32 hours, and the oil layer separated. Formaldehyde-sodium hyposulphite, $NaHSO_2.CH_2O$, may also be used; 10 parts of the compound are employed for the above-mentioned quantities of oil and water, the mixture is heated in a closed vessel to a temperature of 70° C., and then allowed to stand until bleaching has been effected. —W. P. S.

Waxes, varnish, rubber solutions, and analogous substances; Process of rendering —— *uninflammable.* V. A. Boucheron. Fr. Pat. 366,564, May 25, 1906.

THE claim is for the use of carbon tetrachloride as a substitute for the whole or part of the solvents usually employed in the preparation of solutions of waxes, resins, india-rubber, &c.—A. S.

Soap; Method of preparing a light and porous lime ——. C. Ferrier. Fr. Pat. 366,460, May 22, 1906.

CLAIM is made for the creation of a partial vacuum in the saponification of fats by means of lime in an "autoclave." This enables the steam to be maintained at a temperature below 100° C., with the result that the calcium soap produced is only slightly hydrated, very porous, and more suitable for further treatment than that obtained in the usual way.—C. A. M.

[*Zinc*] *Ores or zinc waste; Treatment of mixed or composite* ——, *and the manufacture of zinc white and other products therefrom.* J. W. Worsey, St. Helens, Lancs., and E. Hoal, Liverpool. Eng. Pat. 19,839, Oct. 2, 1905

THE treatment is especially applicable to poor zinc ore or dross, containing zinc (and other metals) in the form of oxide, carbonate, or sulphide. In the last case, the ore &c., is first desulphurised as usual in a kiln. The roasted ore is ground so as to pass through a 10 by 10-mesh sieve, and is then heated with its own weight of sulphuric acid, of 90° T., to which is added about 1 per cent. of nitric acid, sodium nitrate, or an equivalent salt; or else, if the ore contains silver, the nitrate is replaced by sodium chloride. The ore and acid are heated in a pan to about 300° F. until the mixture becomes pasty, the fumes given off being collected, and, together with the sulphur dioxide obtained in the roasting of the ore, utilised for making sulphuric acid. The pasty mixture is next heated at a dull red heat in a muffle furnace, air and steam being passed over it at the same time. When no more fumes are evolved, about 2 per cent. of ground quicklime or dolomite are spread over the charge, and worked into it to render the iron insoluble. The charge is then lixiviated in vats with boiling water, to which, or to the charge, sodium chloride has been added if the ore carries silver or lead, in order to convert these metals into insoluble chlorides. The solution of sulphates obtained, chiefly of zinc and copper, is freed from the latter metal by electrically depositing it on zinc plates. If iron is present, chlorine is added until the solution smells strongly of the gas, and the whole is agitated by blowers. The liquid is then neutralised by adding waste zinc oxide or calcium carbonate until a dark precipitate appears, when air is led in, and the liquid finally boiled, in order to remove any manganese, nickel, or other "subtle" metals present. The purified solution is allowed to settle, and filtered, after which an alkali sulphide or carbonate solution is added, and the whole boiled. The precipitated zinc pigment is filtered off, washed, dried, and ground as usual. (See also Eng. Pat. 3668 of 1900; this J., 1901, 367.)—A. G. L.

Dyeing and printing; Preparation of new products for use in ——, *and as pigments, and their applications.* E. Feilmann. Eng. Pat. 25,693, Dec. 11, 1905. V., page 1040.

FRENCH PATENTS.

Zinc white oil paint. Hentschel et Cie Commandit-Ges. Fr. Pat. 366,465, May 22, 1906.

ZINC white is mixed with an equal quantity (or more) of finely ground silica, and with some calcium carbonate, and then incorporated with a vehicle consisting of linseed oil, Japanese wood oil, and resin. Other preparations containing resin may be used in place of the Japanese wood oil.—A. S.

Silicon monoxide [*Pigment*]; *Method of transforming brown* —— *into white bioxide.* H. N. Potter. Fr. Pat. 366,644, May 28, 1906. Under Int. Conv., June 14, 1905.

SILICON monoxide, in the state of an impalpable light brown powder, is blown through a flame, whereby it is oxidised and whitened, whilst remaining pulverulent Fr. Pat. 360,375 of 1905 (this J., 1906, 546) is referred to. —E. S.

(B.)—RESINS, VARNISHES.

Colophony; Composition of American ——. P. Levy. Ber., 1906, **39**, 3042—3046.

In a former communication the author asserted that the main constituent of American colophony (yielding abietic acid) had the composition, $C_{20}H_{30}O_2$, and he here replies to certain objections of Klason and Köhler based on their examination of the crystallisable acid fraction of the resin of *Pinus abies*. He states that the acid prepared by him differs from that of other investigators chiefly in its greater power of crystallisation and in its considerably higher melting point. The form of the crystals has been proved to be identical with that already described for abietic acid. Fractional distillation *in vacuo* of American colophony has yielded a viscous substance, which, after being purified by treatment with ether and sodium hydroxide solution, is a colourless oil with slight refractive power, having the composition, $C_{19}H_{30}$, and boiling at 210°—211° C. under a pressure of 26·5 mm. It is fairly soluble in ether and benzene, but dissolves with difficulty in alcohol. Its specific gravity at 20° C. is 0·977. It appears to be formed from abietic acid thus—

$$C_{19}H_{29}COOH = C_{19}H_{30} + CO_2.$$

Decomposition of colophony on these lines has already been described by Easterfield and Bagley (this J., 1904, 989), and by Schwalbe on heating colophony under ordinary pressure. In the author's opinion the hydrocarbon, $C_{19}H_{30}$, is probably identical with Deville's "colophene" ($C_{40}H_{64}$) and with the "abietene" of Easterfield and Bagley ($C_{18}H_{28}$). He considers that both these formulæ should be rejected in the light of the formation of the hydrocarbon from abietic acid. The former assumption that abietic acid was derived from colophene is negatived by these facts. The action of phosphorus pentachloride or thionyl chloride on the acid yields the corresponding acid chloride, which, however, cannot be purified sufficiently for analysis, since it is decomposed even on distillation *in vacuo*. By repeated fractionation of the decomposition products the author has isolated a colourless oily body with an intense blue fluorescence. It boils at 200°—202° C. under a pressure of 17 mm., and has the composition, $C_{19}H_{28}$. This substance, which the author terms "abietin," behaves exactly like "abietene" with organic solvents. It appears to be one of the numerous products formed in the dry distillation of colophony, and the author represents its formation from abietic acid by the equation—

$$C_{19}H_{29}COOH = C_{19}H_{28} + CO + H_2O.$$

(See also this J., 1903, 1250.)—C. A. M.

United States Patents.

Varnishing composition and process of making same. A. E. Nienstadt, Newark, N.J. U.S. Pat. 831,736, Sept. 25, 1906.

Clear colourless preparations are obtained by deodorising gum-pontianac, freeing it from acid by treatment with alkali (*e.g.*, ammonia), washing it in cold water to remove the alkali, drying it, and dissolving it in a suitable solvent such as a liquid hydrocarbon. The gum-pontianac may be shredded into thin, irregularly perforated strips before deodorisation.—C. A. M.

Turpentine still. F. M. Gideon, Ballston, Va. U.S. Pat. 832,311, Oct. 2, 1906.

Claim is made for a still containing a basket of wire or like material suspended from the top, and having a perforated bottom kept in position by means of a catch upon a support below. The still has a movable head and a steam pipe beneath the basket, and means are provided for withdrawing the latter.—C. A. M.

Terpenes and rosin; Apparatus for extracting ——. G. A. Kerr, Lynchburg, Va. U.S. Pat. 832,863, Oct. 9, 1906.

The wood to be treated is fed continuously into one end of a still or digester, and discharged at the other end. It is conveyed through and agitated in the still by a conveyor, provided with a hollow shaft with openings through which steam is introduced into the still. At a number of points along the still, the steam, laden with terpenes, can escape. The wood passes by a conduit from the still to an extractor, within which is a similar conveyer having a hollow shaft and openings for the introduction of steam. The extractor is constructed to contain a rosin-extracting bath in it, provided with an outlet.—W. C. H.

Wood oil; Process for treating —— with oxidising agents. A. Kronstein, Karlsruhe, Germany. U.S. Pat. 833,063, Oct. 9, 1906.

See Eng. Pat. 1386 of 1901; this J., 1901, 485.—T. F. B.

French Patents.

Varnish and paint; Manufacture of ——. E. A. Ruch. Fr. Pat. 361,664, Aug. 2, 1905.

Claim is made for the use of aluminium resinate in the preparation of varnishes and paints by incorporating it with oil of turpentine or the like, with or without the addition of colouring matters.—A. S.

Waxes, varnish, rubber solutions, and analogous substances; Process of rendering —— uninflammable. V. A. Boucheron. Fr. Pat. 366,564, May 25, 1906. XII., page 1056.

(C.)—INDIA-RUBBER, &c.

Mollendo biscuit rubber; Analysis of ——, *and the valuation of raw rubber.* D. Spence. Quarter. J. Inst. of Comm. Research in the Tropics, Liverpool Univ., 1906, **1**, 183—184.

The author points out the uselessness of judging raw rubbers from their appearance and physical characters. A specimen of raw Mollendo biscuit rubber, which, from outward appearance, seemed to be of inferior quality, proved to contain less proteid and resinous impurities than are frequently found in the finest Para rubber. Its elasticity was good, and it withstood fairly high temperatures without showing signs of "tackiness." The following are the results of the chemical analysis:—Caoutchouc, 79·05; resin, 1·80; insoluble matter, 2·35 (proteids, 1·6); moisture, 16·6, and ash, 0·50 per cent. The rubber was thus of first-grade quality, but very imperfectly freed from moisture. It was valued at 4*s.* 10*d.* per lb. as compared with 5*s.* 2*d.* per lb. for fine Para rubber.—A. S.

United States Patent.

Gum chicle or other adhesive; Process for purifying ——. S. A. Davis and F. V. Canning, New York. U.S. Pat. 831,041, Sept. 18, 1906.

The material is heated until it "flows"; it is then placed in a screening bag, or sack, and passed between steam-heated compression rollers or rods.—W. P. S.

French Patents.

Rubber substitute; Process for the manufacture of a ——. E. Luserna di Rora. Fr. Pat. 366,191, Jan. 31, 1906.

Forty-eight grms. of glue are dissolved in 352 grms. of hot water, and a solution of 28 grms. of tannic acid in 372 grms. of hot water is added. The precipitate is separated, dissolved in castor oil, and the solution mixed with an equal volume of ether. The mixture is treated with one-tenth of its weight of guncotton, and when this is dissolved, the mass is subjected to the action of "CO_2, CO_2 and C_2H_2" for 10—15 minutes in a closed vessel, after which it is evaporated until it acquires the consistence of rubber. The product can, it is stated, be vulcanised in the same way as natural rubber.—A. S.

Caoutchouc; Manufacture of ——. M. Wildermann. Fr. Pat. 366,704, May 30, 1906.

If from 2 to 4 grms. of raw rubber be treated for some

time in a flask with 30 c.c. of chloroform, and then agitated with a further 270 c.c. of chloroform, and heated on the water-bath, the whole of the rubber dissolves with the exception of mechanical impurities. If, then, alcohol be added drop by drop, without agitation, until a permanent turbidity is produced, and the whole allowed to stand, a considerable quantity of a flocculent precipitate ("caoutchouc α") is obtained. After this is removed, a second quality of caoutchouc ("caoutchouc β") can be separated from the solution by the addition of a further 500 c.c. of alcohol. The evaporation residue of the filtrate from this product contains the remainder of the caoutchouc and the resin. If it be extracted with boiling absolute alcohol, the resin is dissolved, and a third quality of caoutchouc ("caoutchouc γ") is left. The present patent relates to a method of treating raw caoutchouc on an industrial scale, and by an economical process, so as to separate it into caoutchouc α on the one hand, and caoutchouc β and γ and resin on the other, or into caoutchouc α and β and caoutchouc γ and resin. The apparatus for carrying out the process comprises a dissolving vessel, a drainage vessel, condensers, and receptacles for the solvents, together with circulating and exhaust pumps, and the necessary connections. Heating coils are provided in the dissolving and drainage vessels. The crude rubber is placed in pans which are disposed between the turns of the heating coil in the dissolving chamber. A mixture of suitable solvents, of which one (chloroform, benzene, carbon tetrachloride, solvent naphtha) will dissolve the whole of the rubber, whilst the other (ethyl or methyl alcohol) will only dissolve the resins or other constituents which it is desired to remove, is forced by the circulating pump into the dissolving tank, and after a certain time (about 12 hours) the solution containing the resin, &c., is allowed to pass into the drainage vessel, leaving behind either caoutchouc α or caoutchouc α and β, according to the composition of the solvent used. The solvent is next evaporated from the residual caoutchouc and from the solution of resin, &c., the apparatus during this part of the process being connected to the exhaust pump; the vapours pass to the condensers, and the condensed solvent is returned to its receptacle.—A. S.

Waxes, varnish, rubber solutions, and analogous substances; Process of rendering —— uninflammable. V. A. Boucheron. Fr. Pat. 366,564, May 25, 1906. XII., page 1056.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 997.)

Gelatin rendered insoluble by formaldehyde. A. L. Lumière and A. Seyewetz. Bull. Soc. Chim., 1906, **35**, 872—879.

THE maximum amount of formaldehyde which is permanently absorbed by gelatin is between 4·0 and 4·8 grms. per 100 grms. of dry gelatin; this absorption takes place when a 10 per cent. formaldehyde solution acts on dry gelatin; any increase of this concentration results in smaller absorption of formaldehyde; variations of temperature have little effect on the absorption. When gaseous formaldehyde is brought into contact with gelatin, the absorption is much slower, but the maximum is the same as when absorption takes place in aqueous solution. Hot water slowly decomposes formolised gelatin, repeated treatment rendering the gelatin completely soluble. When heated alone at 110° C., formolised gelatin evolves formaldehyde, whilst treatment with 15 per cent. hydrochloric acid resolves it, in the cold, into gelatin and formaldehyde. The aldehydic group could not be detected in formolised gelatin, which is regarded rather as an addition product than a true compound.—T. F. B.

Chromed hide powder question; The ——. F. Kopecky. Collegium, 1906, 97—100, 101—108, 110—116, 117—124, 125—128.

A CONTINUATION of work published in Collegium, 1904, Nos. 116, 117 (this J., 1904, 830). For the manufacture of a good chromed hide-powder, the inferior parts of a hide, such as shoulders and flanks, are quite suitable, and the fibrous part is more so than the compact grain surface. The very serious mechanical difficulties of grinding raw hide are almost entirely overcome by chroming the material before grinding. It is important, however, that the material should be uniformly chromed throughout its substance, as an insufficiently chromed streak in the centre yields an irregular and too soluble powder. Chromed powder absorbs slightly more of the bodies present in tanning materials than unchromed, but excessive chroming causes unsatisfactory action by preventing sufficient absorption of water. Chrome oxide itself has practically no absorptive power for tannin. A good neutral powder is made by chroming hide-bellies previously delimed by a sour bran drench, with 10 per cent. of chrome alum and 3½ per cent. of washing soda on the wet weight of hide. The materials are dissolved separately in the cold, and the mixed solution is added gradually to the hide, revolving with water in a drum. The tannage must be slow, lasting about 18 hours. The leather is neutralised with 3 per cent. of borax, partially dried, and shaved thin in the shaving machine, the grains being finished as leather, and the shavings thoroughly washed, dried, and ground. Good analyses can be made with the shavings of commercial box-calf simply washed and used moist. The use of the chromed powder in detanning by the filter bell, by maceration, and by shaking with the tannin solution was studied, and by experiments with known mixtures of tannin with dextrin and gallic acid, it was shown that a smaller proportion of non-tanning matters was absorbed by the two latter methods, which were therefore to be preferred. The method recommended for the determination of non-tannins is as follows, all manipulations, except detannisation, being carried out according to the rules of the International Association: The dry chromed powder is soaked for at least six hours, and is then squeezed in cheese-cloth until the excess of water is removed. Thirty grms. of this wet powder, still containing about 70 per cent. of moisture as determined by drying a weighed portion, are added to 150 c.c. of the tannin solution, and left for one hour, stirring about three times during this period. The mixture is now poured on to a filter paper and allowed to run through, returning the filtrate twice to the funnel. Fifty c.c. of the filtrate are evaporated, the residue dried and weighed, a correction being made for the water introduced by the wet powder. In the filter bell the absorption of the tannin takes place in a comparatively limited quantity of powder, and the author believes that acids are given up by the portion of powder in which absorption takes place, which are again absorbed in the upper part of the filter bell, where the powder is not acted on by tannin. The tendency of chrome powder to give higher figures for non-tannins in the maceration and shaking methods, as compared to the filter process, is due to lessened absorption of the non-tannin substances, and not to soluble hide substance; the powder even after boiling for half an hour, gives practically the same results as powder soaked in cold water overnight. It was found that, whilst gallotannic acid was readily and completely absorbed by neutral, chromed hide-powder, this was not the case with neutral liquors of mangrove and some other tanning materials unless acid was added. An exhaustive study of the effect of addition of various acids to the chrome powder was made, and it was found that formic or acetic acid were more suitable than either sulphuric or lactic acid, but were too volatile, and that it was more satisfactory to acidify the tanning solution than to use acidulated chrome powder. The author extends his work to the analysis of spent and fermented tan-liquors, which naturally contain organic acids, which are more or less absorbed by the hide-powder. The amount of non-volatile acid absorbed by the hide-powder, and therefore estimated as tannin, can be determined by titration of the residues of tannins and non-tannins respectively, if the nature of the acid can be assumed. Titration by Procter's method with lime-water of residues of a liquor to which known quantities of lactic acid had been added, gave very satisfactory results.—H. Bn.

Sugar cane; Composition and percentage of woody fibre in ——. *Value of bagasse as fuel.* H. Pellet. Bull. Assoc. Chim. Sucr. et Dist., 1906, 24, 277—284.

THE author has made a critical examination of a paper by Prinsen-Geerligs (Archief voor de Java Suikerindustrie, 1906, No. 7), in which results of analytical and calorimetric estimations of various samples of bagasse are given. Fifty-eight samples of woody fibre, from various kinds of sugar cane, gave the following results: Sugar, 2·92—8·46 per cent.; water, 39·25—52·51; ash, 1·04—4·91; silica, 0·75—3·88; and cellulose, 43·43—61·08. The amount of woody fibre in the canes varied between 8·24 and 19·1 per cent. The calorific power of several of the samples of bagasse was also estimated; the results did not differ much, and not nearly enough to explain the great variations observed in the fuel values of different bagasses. The differences also in the amounts of cellulose were insufficient to account for the variations of the fuel value, although canes which give a bagasse suitable as fuel generally contain a high proportion of cellulose. Inferior bagasse has a comparatively low density; the density of the woody fibre is greater the higher the percentage of the fibre in the cane. Prinsen-Geerligs considers that the calorific power of the woody fibre of sugar cane is comparable to that of the woody fibre of young trees, but is of the opinion that the value of the former as a fuel cannot be determined by analysis. He considers also that the great variations in the fuel values of bagasses are due (1) to the volume of bagasse on the furnace bars; (2) to the amount of air which reaches the bars; (3) to the draught. The author agrees with Prinsen-Geerligs's conclusions, and adds that the amount of water vaporised per kilo. of dry bagasse varies with the arrangement of the furnace, the air supply and method of introducing it, the rate of combustion, the draught, the amount of water in the bagasse and condition of the latter, and the method and regularity of charging the furnace. The author considers that the bagasse (free from sugar, water, and ash) from 1000 kilos. of canes containing 10 per cent. of woody fibre, is roughly equivalent to 38—45 kilos. of anthracite. —L. E.

Sucrose; Solubility of —— *in water in presence of invert sugar.* H. Pellet and C. Fribourg. Bull. Assoc. Chim. Sucr. et Dist., 1906, 24, 304—315.

INVERT sugar solutions were prepared by dissolving the requisite quantities of pure sucrose in water, adding 0·5 c.c. of pure concentrated hydrochloric acid, making up to 500 c.c., and then heating in a boiling water-bath until the rotation was constant. The cane sugar solutions inverted in this way varied in concentration from 20 per cent. up to saturation. After the inverted solutions had cooled, they were neutralised, and then saturated with sucrose at about 27° C. The saturated solutions were then analysed, the degrees Brix (apparent and real), the sucrose, reducing sugars, and ash being determined. The authors have drawn the following conclusions from their results: (1) A saturated solution of sucrose can still dissolve invert sugar. (2) If a saturated solution of sucrose be inverted, the solution of invert sugar thus obtained can dissolve a further quantity of sucrose. (3) In an invert sugar solution saturated with sucrose at 29° C., and containing approximately as much sucrose as invert sugar, 1 part of water contains 3·5 parts of solid matter, whereas in the case of a sucrose solution, saturated at the same temperature, 1 part of water contains 2·16—2·20 parts of solid matter. In an invert sugar solution saturated with sucrose at 29° C., and containing 68 parts of sucrose per 100 parts of invert sugar, 1 part of water contains 3·90 parts of solid matter. (4) Hence it follows from (3) that the solubility coefficient of pure sucrose is inapplicable in the case of after-products of cane sugar manufacture when these contain considerable quantities of invert sugar. (5) In the case of solutions containing invert sugar and sucrose, it may be admitted that by successive crystallisations, a solution of invert sugar saturated with sucrose will be obtained, in which the proportion of sucrose to invert sugar is 0·69:1. Hence the molassagenic coefficient of invert sugar under such conditions is 0·69. This figure, however, is not applicable to solutions such as cane molasses, which contain organic non-sugar and salts; these substances modify the molassagenic action of invert sugar. From the composition of a sample of average final molasses, the authors have calculated a mean molassagenic coefficient—1·05—applicable to the total non-sugar present in any sample of sugar. The authors have also determined the viscosities of the saturated solutions, and have found that the viscosity increases rapidly with the percentage of invert sugar. —L. E.

Coal; New artificial ——, *composed of a mixture of beet-pulp and powdered coal, wood charcoal, or coke, and an agglomerant.* J. P. Remaury. Fr. Pat. 366,141, April 28, 1906. II., page 1054.

XVII.—BREWING, WINES, SPIRITS, &c.

(*Continued from page* 1000.)

Barley; Nature of the phosphoric acid compounds in ——, and the changes which they undergo in the malting processes. W. Windisch and W. Vogelsang. Woch. f. Brau., 1906, 23, 516—519 and 556—558.

The authors have taken advantage of the observation of Schulze and Castoro, that freshly precipitated calcium phosphates are soluble in a perfectly neutral solution of ammonium citrate, as a basis for an analytical separation of inorganic phosphates from phosphoric acid in organic combination. For this purpose, 100 c.c. of barley or malt extract were treated with 10 c.c. of a 10 per cent. solution of calcium chloride, and made alkaline with ammonia. The calcium phosphate was filtered off and washed, and the precipitate and filter were digested with 50 c.c. of a 10 per cent. solution of ammonium citrate for 24 hours, the phosphoric acid in the solution being then precipitated with magnesia mixture. For the determination of the total phosphoric acid, the organic compounds in the infusion were hydrolysed by boiling with sulphuric acid, and the phosphoric acid was precipitated by molybdate. In this way it was found that a cold-water infusion of barley contained a considerable quantity of total phosphoric acid, a large portion of which was in the inorganic state. But when the infusion was made under conditions which precluded the activity of enzymes, *e.g.*, in the presence of 1 per cent. of hydrochloric acid or after treatment of the barley with boiling alcohol, the whole of the phosphoric acid was in the organic state. Raw barley, therefore, contains no inorganic phosphates; these are only produced when the organic compounds are exposed to the hydrolytic action of the enzymes as in the steeping and malting processes. This conversion of the phosphoric acid compounds, already far advanced in the case of malt, may sometimes be completed during the process of the saccharification of the mash, especially if germination has been conducted in the dark. The hydrolysis of the organic phosphates during germination appears to be retarded by sunlight, as is indicated in the table below under the heading of "malts." This table shows the results obtained with two samples of barley, germinated in the laboratory, and with the malts obtained from them. Sample A was exposed during germination to direct sunlight, whereas Sample B was treated only in diffused daylight. The values for phosphoric acid (as P_2O_5) are expressed in terms of the dry substance in each case.

Yeasts and fungi; Assimilation of the auto-digestion products of beer yeast by various races of ——. II. P. Lindner and F. Stockhausen. Woch. f. Brau., 1906, 23, 519—523.

The authors have repeated and extended the observations of Lindner, Rülke, and Hoffmann (see this J., 1905, 1120) on the availability of the nitrogenous products of the auto-digestion of beer yeast as nutrients for the growth of various yeasts and fungi. The different products isolated were incorporated separately in agar media containing dextrose and salts, but no other nitrogenous nutrient. A difficulty presented itself in the fact that many of the yeasts showed a distinct development on the control plates to which no nitrogenous substance had been added. This was due to the presence of residues of nitrogenous matter in the agar-agar employed. These matters were ultimately eliminated by exposing the agar to a spontaneous fermentation which took place with the development of butyric acid; the product was then thoroughly washed with water. The results of the present extended series of experiments are summed up in several tables. They indicate that as a rule the top-fermentation yeasts are most particular in the selection of their nitrogenous nutrition, and that the bottom-fermentation yeasts come next. The only digestion product generally available for all the yeasts is leucine. Other substances, more or less available for several of the species, are tyrosine, adenine, asparagine, aspartic acid, and ammonium sulphate. Certain species of top-fermentation distillery yeasts, and the English top-fermentation beer yeasts in general, are capable of assimilating arginine in addition to the other substances mentioned above. The bottom-fermentation beer yeasts are generally distinguished from most of the top-fermentation varieties by their stronger development on tyrosine, adenine, and ammonium sulphate. The wild yeasts, *S. pastorianus III., and ellipsoideus I.* and *II.*, behave like the bottom yeasts, only more vigorously. *S. turbidans* [*ellipsoideus II.*] occurs in both top and bottom fermentation forms of constant type; these two forms behaved alike in these experiments, except that the growths of the top-fermentation forms were more vigorous. In strong contrast with the highly selective behaviour of the above culture and "wild" yeasts is the almost omnivorous behaviour of the mycoderma and anomalous yeasts, which are capable of assimilating nearly all the digestion products of beer yeast to a full extent, and many of which even assimilate potassium nitrate.—J. F. B.

Micrococcus (M. esterificans) which forms "fruit-esters." Beck. Arbb. Kais. Ges.-A., 24, 256—263. Chem. Centr., 1906, 2, 1078.

Micrococcus esterificans was discovered by the author ten years ago in a sample of butter. In the arrangement of its colonies it resembles *Staphyloc. pyogenes aureus*. On ordinary nutrient media it develops an aroma of "fruit-esters," changing after some days to one resembling that of freshly-baked bread. A characteristic property of the organism is the formation of an orange colouring matter on gelatin and agar. It grows on milk, with formation of "fruit-esters," but without curdling the milk, or causing it to turn sour. It does not produce indole, phenol, or nitrite; in saccharine media no carbon dioxide

rmed, nor is hydrogen sulphide produced in nutrient ions of peptones. The constituent to which the ant aroma is due, is soluble in ether, chloroform, and on bisulphide; it appears to be present in the cell-tance, and to be combined with a fatty compound. —A. S.

r; *Rapid fermentation of* ——. L. Meunier. Bull. soc. Chim. Sucr. et Dist., 1906, **24**, 320—321.

means of utilising the excess supply of apples in in seasons, over that required for cider manu-re, the author recommends the conversion of apple into brandy. Under ordinary conditions however, must ferments very slowly. To remedy this, it d be treated with 10—15 grms. of ammonium phate per hectolitre, and should be fermented with orous yeast at 20°—25° C. Under such conditions, days are sufficient for the complete fermentation must of average gravity. The brandy obtained the fermented wort is of satisfactory quality.—L. E.

s; *Algerian red and white —— of the Mascara trict.* E. Jalade. Bullet. Féd. Pharm. du Sud-ouest du Centre. 1906, **30**, 233—241.

red wines of the Mascara district are eminently suit-to replace Spanish wines for blending, as "*vins de ge.*" They possess sufficient colour, extractive er and alcohol, to allow them to be used advan-usly to improve certain poorer French vintages. natural bouquet is agreeable, so that they may be at once, whilst when properly matured they acquire few years characters approaching those of the best ls of Burgundy. The white wines, in addition to value for ordinary use, are suitable for employment edicinal or pharmaceutical purposes. The charac-f these wines are shown in the following table of the s obtained with 15 samples of red wine and 11 of white.

—J. O. B.

English Patents.

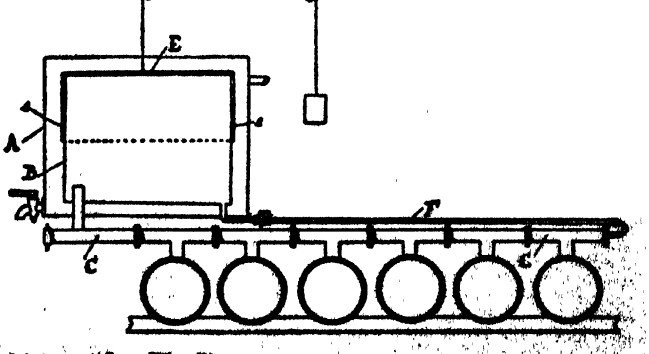
; *Treatment* [*roasting*] *of* ——. E. M. Cowell, Saxmundham, Suffolk. g. Pat. 26,041, Dec. 14, 1905.

invention relates to the preparation e amber, crystal, or black malt used olouring and flavouring beer, &c., and sts in roasting malt or green (raw) in rotating cylinders, a current of ir being passed through the cylinders g the operation. The quantity of air ulated according to the object for the material under treatment is ded.—W. P. S.

asic malt extracts; Process for con-ting —— into solid form for rendering same durable. I. Pollak, Vienna. g. Pat. 9866, April 27, 1906.

n concentrated malt extracts are mixed into a stiff a with 30 to 40 per cent. of fine flour of germinated cereals, rich in diastase. Simultaneously with the absorption of water, the hydrolysis of the starch by diastase begins, two molecules of starch taking up one of water, forming dextrins and finally maltose. The dough, on standing *in vacuo*, becomes quite hard, and can be moulded into any required form, or powdered. The product contains a greater proportion of diastase than ordinary malt extract, is more convenient and cleanly to use, and can be kept as long as desired.—S. R. T.

Fermenting vats. J. House, London. Eng. Pat. 18,836, Sept. 18, 1905.



The invention relates to apparatus of the type described in Eng. Pat. 22,484 of 1899 (this J., 1900, 165). Claim is made for providing both the fermenting vat and the gas and yeast tank with water jackets, so that they can be kept at any desired temperature.—S. R. T.

Mash tuns and infusion decoction and digester vessels and the like. J. House, London. Eng. Pat. 18,837, Sept. 18, 1905.

The lower part of the mash tun, with sides and perforated false bottom, rests on ribs within an annular containing chamber. Immediately below, and opening centrally into the vat, is a wort-receiver, or underback, having a vertical circular grating or screen, and two lateral openings, the one to admit air, the other connecting with a pump. The mash tun is provided with a central hollow shaft, opening into radial loops or tubes, or concentric spiral tubular coils, for the circulation of steam or hot water. Where radial loops are fitted, the shaft is partitioned in such manner as to insure perfect circulation through them. In addition, the shaft carries arms or vanes, provided with inclined or helical faces, for the stirring or convection of the contents of the tun.—S. R. T.

Fermentation [*in casks*]; *Process of* ——. E. J. Vloeberghs, Norderwijck, Belgium. Eng. Pat. 5135, March 2, 1906.

An arrangement is described by which the system of fermentation in casks can be carried out without exposing the froth expelled from the bung-holes to contamination air. The bung-holes of the fermentation casks are connected with a horizontal main, C, which is constructed in sections that can be readily dismounted. The main, C, conducts the froth, expelled from the casks, into a tank, B, which is jacketed by water of any desired temperature contained in an outer tank, A. The tank, B, is covered by a hood, E, closed by a water-seal after the manner of a gasometer. The hood is so counterbalanced as to rise and expose holes, *e*, in its sides, by which the gas can escape, as soon as the pressure reaches a predetermined limit. The liquid which condenses from the froth collects in the bottom of the tank, B, and can be returned to the fermentation casks by opening a cock in the small pipe, *F*.

When barm is required, it can be collected from the main, C, at a certain stage of the fermentation.—J. O. B.

Waste, juices, syrups, and scented extracts; Process for the preparation of concentrated ——. E. Monti, Turin, Italy. Eng. Pat. 9205, April 18, 1906.

See Fr. Pat. 366,338 of 1906; this J., 1906, 947.—T. F. B.

Wine and the like; Method of and apparatus for improving the quality of ——. F. O. Nilsson and J. A. Jonsson, Stockholm, Sweden. Eng. Pat. 13,563, June 13, 1906. Under Int. Conv., June 16, 1905.

The invention relates to an apparatus for subjecting wine and other liquors to strong preliminary agitation, and then to simple centrifugal rotation and filtration. A bowl, of the type of an ordinary milk separator, contains a central cylindrical chamber surrounded by two concentric cylinders, the space between which is packed with a filtering material. The central cylinder is fitted with radial perforated wings, and the wine falling upon these is violently agitated. Passing on, the liquor is forced through the filter and out of the bowl again.—S. R. T.

United States Patent.

Wort; Proces of fermenting ——. H. A. Schalk, New York. U.S. Pat. 831,748, Sept. 25, 1906.

The process provides for the continuous fermentation of wort in a series, or battery, of vats. After fermenting the wort in the first vat, a portion is discharged into the next vat, and so on, the partly-filled vats being supplied with fresh quantities of unfermented wort. The contents of the vats are subjected successively to aeration and to the action of air which is forced over the surface of the liquid.—W. P. S.

French Patents.

Antiseptics and yeasts acclimatised thereto for grain distillery purposes. G. Jacquemin and G. Fritsche. Fr. Pat. 361,643, July 22, 1905.

A mixture of formaldehyde and milk or other nitrogenous vegetable or animal substance is added to the wort, which is then fermented by means of yeast or saccharifying mould fungi, which organisms have been previously acclimatised to formaldehyde by successive cultivations in media containing progressively increasing additions of that substance.—C. S.

Yeast; Method of cultivating ——. K. Kruis and F. Ringhoffer. Fr. Pat. 366,533, May 23, 1906.

The wort or culture medium is prepared by mixing beet juice with potato juice freed from starch, the two being acidified, sterilised, and filtered either before or after mixing. Alternatively, the pulp of beet and potatoes in the fresh or dried state can be employed, the former being lixiviated and the latter saccharified, whilst the liquids resulting from these treatments are converted into a nutritive wort by adding the substances in which they are deficient, and by sterilisation and filtration.—C. S.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 1001.)

(*A.*)—FOODS.

Arachis oil-cake; Poisonous action of ——. E. Krüger. Chem.-Zeit., 1906, 30, 999.

In November, 1904, several cows died with symptoms of acute poisoning after eating fodder containing arachis meal. Examination of the meal showed the presence of a certain proportion of castor seeds in addition to other foreign substances, but feeding experiments on sheep and rabbits gave negative results, all the animals remaining healthy. It is suggested as a possible explanation that the poisoning may have been due to products of the reaction between certain constituents in the arachis meal and in the fodder given with it.—C. A. M.

Butter; Detection of cocoanut oil and margarine in ——. L. Bodin. XXIII., page 1069.

"Crude fibre"; Determination of cellulose, lignin, and cutin in ——. J. König. XXIII., page 1069.

United States Patents.

Pasteurising process. H. E. Weber, Canton, Ohio. U.S. Pat. 831,812, Sept. 25, 1906.

The liquid is caused to flow by gravity, opposed by centrifugal force, in a thin film of gradually increasing thickness over the treating surface.—W. P. S.

Animal tissues [Meat]; Preserving ——. C. E. Calm, Chicago, Ill. U.S. Pat. 832,180, Oct. 2, 1906.

Meat or other animal tissue is treated with ferric nitrate in the proportion of 4 oz. of the salt to 100 lb. of meat, &c., whereby the growth of bacteria and other micro-organisms is arrested.—A. G. L.

(*B.*)—SANITATION; WATER PURIFICATION.

Industrial Diseases Committee.

Times, Nov. 1, 1906.

The departmental committee which was recently appointed "to inquire and report what diseases and injuries, other than injuries by accident, are due to industrial occupations, are distinguishable as such, and can properly be added to the diseases enumerated in the Third Schedule of the Workmen's Compensation Bill, 1906," has now begun its inquiry. The committee proposes to investigate the following diseases and injuries which have been suggested for its consideration—*viz.*, gradual poisoning from the vapour of carbon bisulphide, dinitrobenzene, dinitrotoluene, and aniline; gradual poisoning from carbonic oxide gas, sulphuretted hydrogen gas, and chlorine gas; alkaloidal poisoning from African boxwood in shuttlemaking; illness set up by nitrous fumes, hydrochloric acid fumes, ammonium chloride fumes, and sulphur fumes; compressed air illness (caisson disease); chrome ulceration of the skin; various trade eczemas; fibrosis of the lungs from inhalation of silicious or metallic particles (potter's asthma and grinder's phthisis); pneumonia from inhalation of basic slag dust; miner's nystagmus and miner's "beat knee" and "beat hand"; neurosis due to vibration; cardiac dilatation in slate quarries; and glanders. Correspondence relating to the inquiry should be addressed to Frank Elliott, Esq., secretary to the committee, at the Home Office, Whitehall, S.W. Anthrax, ankylostomiasis, and poisoning by lead, mercury, phosphorus, and arsenic are already included in the Third Schedule of the Workmen's Compensation Bill, and are not, therefore, within the committee's terms of reference.

English Patents.

Air; Purification of vitiated ——. A. H. Atteridge and the British Submarine Boat Co., Ltd., London. Eng. Pat. 19,012, Sept. 20, 1905.

The air is forced, by means of a fan, through a cylinder containing granular soda-lime, and then through water acidulated with an organic acid. A filter containing "carbolised tow" is placed at each end of the soda-lime cylinder, and a small proportion of oxygen is mixed with the air before, or after, its passage through the acidulated water.—W. P. S.

Sewage sludge and other waste matters of an organic origin; Destructive distillation of ——, *for the recovery of by-products such as ammonia and oil therefrom, and the utilisation of the residue.* J. C. Butterfield and G. Watson. Eng. Pat. 19,502, Sept. 27, 1905. III., page 1035.

Furnace for consuming rubbish and other matter not easily consumed. H. Self, Düsseldorf, Germany. Eng. Pat. 22,847, Nov. 7, 1905.

The firegrate of the furnace is pivoted so that the hot clinker may be discharged into a truck running on rails in a closed space below the furnace. The truck is provided with a false perforated bottom, and a blast of air is driven

into the space below the false bottom, and, passing up through the hot clinker, enters the furnace through the firegrate. An alternative method of obtaining a hot-blast for the furnace is to draw air through the clinker in the truck, and to introduce the heated air into a space below the grate of the furnace.—W. P. S.

Water and other liquids; Sterilising, softening, and heating ——, *and apparatus therefor.* G. W. Westrope and E. E. Cooper, London. Eng. Pat. 26,527, Dec. 20, 1905.

THE water to be treated is passed from a small reservoir into a vessel provided with a number of baffle-plates arranged horizontally. The height of the water in the vessel is so regulated by the position of the small reservoir and the level of the water in the latter, that, when cold, the surface of the water is below the overflow of the vessel, but when the temperature is raised to boiling point, the water overflows continuously from the top of the vessel. Any suitable means of heating may be employed; the overflow may consist of an inclined pipe or be formed by a conical top to the vessel ending in a pipe, and the vessel may be open or closed. If desired, the hot water leaving the vessel can be used for partially heating the incoming water. The heating arrangement may be regulated automatically, and a waste pipe is provided in the small reservoir to take up any leakage from the ball-tap admitting the water to the said reservoir.—W. P. S.

Incrustation in water receptacles; Composition for removing and preventing ——. S. Rubert and P. Rubert, Barcelona, Spain. Eng. Pat. 6806, March 21, 1906. Under Int. Conv., Dec. 9, 1905.

THE composition consists of a mixture of acid sulphates, neutral phosphates, "potassium and sodium oxides," and a colouring matter. Varying proportions of these constituents are used, and the composition is prepared in the form of a paste, liquid, or powder, or it may be compressed into cakes.—W. P. S.

UNITED STATES PATENT.

Incrustation; Preventing ——. S. Rubert and P.R. Laporta, Barcelona, Spain. U.S. Pat. 831,107, Sept. 18, 1906.

SEE Eng. Pat. 6806 of 1906; preceding these.—T. F. B.

FRENCH PATENTS.

Water; Process for the purification of ——. G. Lambert. First Addition, dated July 19, 1905, to Fr. Pat. 361,435, May 3, 1905 (this J., 1906, 862).

CALCIUM carbonate is used instead of the sodium carbonate mentioned in the original specification, and the water, after treatment, is drawn off from the settling tank through a floating filter. In cases where large quantities of water are to be treated, the reagents are mixed with the water in a tank provided with a stirring device; each tankful of treated water is then led into the settling tank, and filtered.—W. P. S.

Water; Sterilisation and clarification of ——. C. F. J. Hy. Fr. Pat. 361,642, July 22, 1905.

THE water is treated with a mixture consisting of calcium permanganate, four parts, and anhydrous sodium carbonate, 26 parts; the mixture is added, with constant stirring, in quantities of 0·1 grm. per litre, until the water has a persistent red coloration. A mixture, consisting of anhydrous ferrous sulphate, 10 parts, and anhydrous aluminium sulphate, 20 parts, is then added in quantity equal to the amount of the permanganate mixture used, and the precipitate formed allowed to settle. Finally, the water may be filtered.—W. P. S.

Water; Process for the purification of —— by means of suspended filter-beds. L. Girerd and J. Drapier. Fr. Pat. 368,614, May 28, 1906.

THE water is led into the bottom of a small settling tank placed at the top of a tall cylindrical vessel, the latter is divided into compartments by a number of horizontal plates, the lower plates being perforated whilst the upper plate is non-perforated, and forms the bottom of the upper compartment of which the settling tank forms a part. The water rises in the settling tank, overflows through a sieve, and gradually fills the upper compartment. A siphon, contained in a box, intermittently discharges small quantities of the water from the upper compartment on to a layer of filtering material placed on the perforated bottom of the next lower compartment; from the latter, the water drips on to two more layers of filtering material contained in the lower compartments of the vessel, and is finally collected in a channel at the bottom. The size of the settling tank and of the upper compartment, and the rate of the flow of the water, are so regulated that the water takes about one hour to pass through the tank, and five hours through the upper compartment. The layers of filtering material in the two upper filter compartments consist of a calcined mixture of iron oxide, manganese dioxide, and barium oxide, whilst the lowest layer of filtering material consists of sifted volcanic cinders.—W. P. S.

Water; Process and apparatus for sterilising —— by means of ozone. M. Otto. Fr. Pat. 366,728, May 31, 1906.

THE apparatus consists of a large metal cylinder mounted horizontally on bearings at either end, supporting rollers being also provided along its length. The interior of the cylinder is filled with inert, granular substances, such as flint stones. Pipes passing through stuffing-boxes enter both ends of the cylinder, and serve as the inlet and outlet for the water to be treated; smaller pipes are also provided for the introduction of the ozone, and for the discharge of the exhausted gas. The water supply is so regulated that the cylinder is kept about two-thirds full, and by rotating the cylinder, the ozone is thoroughly mixed with the water. The action of the ozone is increased if pressure be allowed to form in the cylinder. A fixed cylinder may be employed, but in this case the ozone must be led by bent pipes to the lower part of the cylinder.—W. P. S.

Air; Process for the regeneration and purification of ——. The Roessler and Hasslacher Chemical Co. Fr. Pat. 366,525, May 23, 1906. Under Int. Conv., March 9, 1906.

THE air is forced through a cylinder, where it is brought into contact with an alkali peroxide, preferably sodium peroxide; the carbon dioxide is thus removed, and the air enriched by oxygen liberated as the result of the action of the moisture contained in the air on the peroxides. The sodium peroxide is contained in a rotating wire-gauze cylinder mounted in the main cylinder; the rotation causes the coating of carbonate, &c., to be rubbed off the surface of the lumps of peroxide, and exposes a fresh surface of the latter to contact with the air.—W. P. S.

(C.)—DISINFECTANTS.

FRENCH PATENTS.

Formaldehyde disinfectant; Process of preparing a ——. Chem. Fabr. Flick in Ichendorf, G.m.b. H. Fr. Pat. 366,307, May 16, 1906.

ONE hundred parts of 40 per cent. formaldehyde solution and 20 parts of 96 per cent. alcohol are added to a mixture of 70 parts of glycerol with 30 parts of oleic acid. Potassium hydroxide solution is then added until a clear solution is obtained; about 6 c.c. of 33 per cent. potassium hydroxide solution are required. Sodium hydroxide or ammonia may be used in place of potassium hydroxide, and the oleic acid may be replaced, wholly or in part, by resin.—W. P. S.

Formaldehyde; Production of gaseous ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 366,604, May 25, 1906. Under Int. Conv., July 19 and Aug. 3, 1905.

THE process consists in treating with water mixtures of polymerised formaldehyde (paraformaldehyde, trioxymethylene) with metal peroxides having an alkaline reaction, or with salts of peracids derived from these

peroxides. For example, a vigorous evolution of gaseous formaldehyde is obtained by adding 15—20 c.c. of water to 25 grms. of a mixture of 1 part of paraformaldehyde and 2½ parts of barium dioxide.—A. S.

GERMAN PATENT.

Tar oils for impregnating, preserving, and disinfecting purposes; Process for working up heavy ——. H. Nördlinger. Ger. Pat. 168,611, Jan. 21, 1905. III., page 1036.

XIX.—PAPER, PASTEBOARD, &c.

Celluloid-like substances; Method for producing ——. O. B. Thieme, Potsdam, Germany. U.S. Pat. 831,488, Sept. 18, 1906.

THE whole or a part of the camphor usually employed in the manufacture of celluloid is replaced by urea in which the hydrogen associated with the nitrogen is replaced by organic radicals. (Compare Claessen; Fr. Pat. 364,604; this J., 1906, 368.)—J. F. B.

FRENCH PATENTS.

Paper pulp; Use of a mixture of gypsum and plaster of Paris as a loading for ——. A. Monin. Fr. Pat. 366,112, May 12, 1906.

CRUDE natural calcium sulphate (gypsum) when used as a loading for paper pulp does not form a pasty mass with water, and is consequently not easily retained by the pulp. On the other hand, the dehydrated sulphate (plaster of Paris) forms hard lumps. According to this invention a mixture consisting of three parts of gypsum and one part of plaster of Paris, or other suitable proportions, forms a thick pasty mass with water equal to china clay and talc, and far superior to either of the two constituents used separately.—J. F. B.

Waterproofing solution [coal-tar dissolved in petroleum, for leather, paper, &c.]. G. Mongauzi. Fr. Pat. 365,374, March 26, 1906. XIV., page 1059.

Celluloid; Production of products resembling ——. Badische Anilin und Soda Fabrik. First Addition, dated May 16, 1906, to Fr. Pat. 363,846, March 5, 1906. Under Int. Conv., Aug. 8, 1905. (See Eng. Pat. 8077 of 1906; this J., 1906, 608.)

SYMMETRICAL methylbenzoyltrichloranilide can replace the acetyl derivatives of tri- or polychlor-alkylanilines in the production of celluloid, as substitutes for camphor. The other benzoyl derivatives of halogenated alkylanilines are not sufficiently soluble for the purpose, and do not cause the nitrocellulose to swell sufficiently (see Eng. Pat. 10,228 of 1906; this J., 1906, 866).—T. F. B.

Textile fibres [Artificial silk] from cupro-ammoniacal solutions of cellulose; Process of manufacturing lustrous threads of ——. Soc. anon. "La Soie Nouvelle." Fr. Pat. 365,057, April 10, 1906. V., page 1041.

Cork; Manufacture of artificial ——. H. Coale. Fr. Pat. 366,586, May 26, 1906.

CUTTINGS of cork and other cork waste are reduced to a granular condition. The granulated material is then packed into a vessel having the shape of an inverted truncated cone with a base of wire gauze and a hinged cover at the smaller end. This vessel containing the granulated cork is immersed in a bath of dilute sulphuric acid, which dissolves some of the impurities; the hinged cover is then raised, and the particles of good cork float out to the surface whilst the heavy inferior particles remain in the vessel. The floating cork is removed, bleached, and packed into moulds together with an agglutinating agent, preferably albumin. The moulded masses are then subjected to moist heat in the form of steam in order to coagulate the albumin, and are finally dried. If necessary, the finished product may be softened by glycerol.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 1003.)

Morphine; Separation of —— *from solution in glycerol.* H. M. Gordin and W. H. Harrison. Amer. J. Pharm., 1906, 78, 464.

THE glycerol solution of morphine sulphate is treated with excess of *N*/1 iodine solution, and the mixture is diluted with water to about three times its volume. On standing overnight, about 80 per cent. of the morphine present crystallises out as morphine triodide hydriodide. The crystals are collected, washed with water containing a little Wagner's reagent, and dissolved in a few c.c. of 10 per cent. sulphurous acid solution. On adding a slight excess of potassium carbonate to this, and heating to 60° C. for about a minute, the alkaloid commences to crystallise out within half an hour from the cold liquid.

Brucine; Erlenmeyer jun.'s cinnamic acid salts of ——. W. Marckwald und R. Meth. Ber., 1906, 39, 2596—2600.

ERLENMEYER, jun., has described two isomeric brucine salts of cinnamic acid, melting at 107°—113° C. and 135° C. respectively, and further has based important theoretical speculations on their existence. The authors now show that the salt melting at 113° C. crystallises with a molecule of alcohol, and has the composition $C_{23}H_{26}O_4N_2.C_9H_8O_2+C_2H_6O$. The other salt, which they obtain by mixing cinnamic acid with brucine in the proportion of 2 mols. to 1 mol., has a rotation $[\alpha]=-4{\cdot}2°$, melts at 135°, and has the composition $C_{23}H_{26}O_4N_2$ $(C_9H_8O_2)_2$, in which the second molecule of acid acts as a molecule of acid of crystallisation. Erlenmeyer jun.'s salts are thus not isomerides.—E. F. A.

Eriodictyon californicum leaves; Chemistry of ——. F. B. Power and F. Tutin. Proc. Amer. Pharm. Assoc., 1906. Pharm. J., 1906, 77, 381.

THE leaves yielded 29·2 per cent. of a complex mixture of crude resinous substances, about 75 per cent. of the mixture being soluble in ether. Three new substances of phenolic nature were isolated from the leaves:—*Eriodictyol*, $C_{15}H_{12}O_6$ (m. pt., 267° C.), about 0·23 per cent.; *homo-eriodictyol*, $C_{16}H_{14}O_6$ (m. pt., 223° C.), about 3 per cent.; and about 0·014 per cent. of a yellow substance, $C_{16}H_{12}O_6$, at present unnamed. Other constituents of the leaves are about 0·7 per cent. of triacontane (m. pt., 65·2° C.), and pentatriacontane (m. pt., 74·5° to 75° C.); about 0·5 per cent. of free and combined acids, including formic, acetic, cerotic, and other acids in the free state, and the glycerides of formic, butyric, cerotic, and other acids; a very small amount of a phytosterol (m. pt., 136° to 137° C.); a considerable amount of dextrose; and about 0·1 per cent. of a yellow volatile oil possessing the characteristic odour of the drug. Eriodictyol was obtained in small fawn-coloured plates, which darkened and melted to a red liquid at 267° C. It is moderately soluble in hot alcohol and in acetic acid, very sparingly soluble in boiling water, and insoluble or very sparingly soluble in other organic solvents than those named, but it dissolves readily in solutions of the fixed alkalis and alkali carbonates, forming almost colourless solutions, which rapidly absorb oxygen and assume a deep brown colour. Homo-eriodictyol was obtained in lemon-yellow plates, which are more sparingly soluble in water than eriodictyol, but more readily soluble in alcohol or acetic acid. A drop of ferric chloride solution added to dilute alcoholic solutions produces an intense red-brown colour with homo-eriodictyol, and a deep greenish-brown, changing rapidly to pure brown, with eriodictyol. Basic lead acetate affords a bulky yellow precipitate with eriodictyol in saturated aqueous solution, but homo-eriodictyol is not appreciably precipitated by the same reagent. The existence of the "ericolin" of Thal was not confirmed, and "ericinol," the assumed hydrolytic product of that body, appears to be furfural, the chief volatile body resulting from the action of a dilute mineral acid on a purified extract of the leaves. The "eriodictyonic acid" of Quirini appears to have consisted of impure homo-eriodictyol.—A. S.

Rheum rhaponticum; Constituents of the root of ——. A. Tschirch and Christofoletti. Schweiz. Woch. Chem. Pharm., 1906, 44, 361—370.

THE crushed root was extracted with 70 per cent. alcohol, then with 95 per cent. alcohol, and finally with 5 per cent. aqueous ammonia. The latter extract was red in colour, but contained only traces of oxymethylanthraquinones.

Rhaponticin, $C_{28}H_{24}O_9$, was obtained in colourless, tasteless prisms, m. pt. 231° C. (after becoming coloured at 210°), by evaporating the 70 per cent. alcoholic extract to a syrupy consistence, and treating it with ether. On standing, rhapontiicin separated out and was purified by re-solution in 70 per cent. alcohol, precipitation with water, and recrystallisation from 70 per cent. alcohol, after treatment with animal charcoal. It is insoluble in ether, benzene, and chloroform; soluble in hot water, acetone, alcohol, and acetic acid; readily dissolved, especially on warming, by acetone or alcohol diluted with water. It contains one methoxyl group, and yields a diacetyl compound, m. pt. 138° C. Rhapontiicin only slightly reduces Fehling's solution when boiled.

Rhapontigenin, $C_{17}H_{22}O_9$, m. pt. 180°—181° C., is obtained by the cautious hydrolysis of rhapontiicin with dilute sulphuric acid, and shaking out with ether. The crude rhapontigenin obtained on distilling off the ether is purified by recrystallisation from alcohol; it then forms well-defined colourless needles, readily soluble in acetone, ether, alcohol, ethyl acetate, acetic acid, and pyridine; sparingly soluble in cold water and only slightly more so on heating; insoluble in benzene and in light petroleum spirit. It contains a methoxyl group, and yields dibenzoyl (m. pt., 145°—146° C.) and diacetyl compounds (m. pt., 108°—110° C.).

Oxymethylanthraquinones.—The ethereal liquids, after the precipitation of the rhapontiicin, when evaporated to dryness and treated with 10 per cent. sodium carbonate solution, leave chrysophanic acid undissolved. After partial purification, this has the m. pt. 181°—182° C., but it still contains 1·48 per cent. of methoxyl. Pure chrysophanic acid has the m. pt. 196° C. It is suggested that this should be named chrysophanol, to distinguish it from the chrysophanic acids, containing variable quantities of methoxyl, obtained from different drugs.

Tetrahydromethoxychrysophanol.—The sodium carbonate solution from the above contained neither rhein nor emodin, but gave a new body, tetrahydromethoxychrysophanol, $C_{16}H_{16}O_5$, in golden yellow scales, m. pt. 216° C., on shaking out with toluene and precipitating the toluene solution with light petroleum spirit.

Anthraglucosides.—The mother liquors, after the separation of the free oxymethylanthraquinones, gave, after hydrolysis with alcoholic potash, a further yield of oxymethylanthraquinone, rhubarb-red, and rheogimin, thus indicating the presence of an anthraglucoside.

Tetrahydromethylchrysophanol, $C_{16}H_{16}O_4$, crystallising in orange-red, glittering scales, m. pt. 195°—196°, was isolated by shaking out with ether the alkaline liquid after the above hydrolysis. It is soluble in chloroform, ether, benzene, and acetone, and is precipitated from benzene solution by light petroleum spirit. It is insoluble in sodium carbonate solution, and very slightly soluble, with a red colour, in ammonia. It gives a diacetyl compound, m. pt. 205° C.—J. O. B.

Juniperus phœnicea (L.); Essential oil of ——. J. Bodin. Bull. Soc. Chim., 1906, 35, 922—925.

THE fact that oil from *Juniperus phœnicea* has been supplied in place of that from *Juniperus sabina* is due to the close resemblance between the two shrubs. In examining the oil of *J. phœnicea* the author gives some data in addition to those found by Umney and Bennett (see this J., 1906, 88). The oil was distilled from the twigs of young plants cut at the beginning of the winter. The constants for five samples were:—

	I.	II.	III.	IV.	V.
Sp. gr. at 15° C.	0·868	0·867	0·868	0·868	0·867
Optical rotation in 100 mm. tube	+3°28′	+2°54′	+3°12′	+4°12′	+3°36′

The samples were soluble in 4—5 parts of 90 per cent. alcohol. The smell, which is characteristic, resembles that of true savin oil. The yield from the plants was 0·4—0·5 per cent. Of the oil prepared by the author 70 per cent. distilled between 150° and 180° C. The sp. gr. at 19° C. was 0·858, and optical rotation in a 100 mm. tube, +2° 56′. The oil consisted of pinene, with traces of camphene and phellandrene.—F. SEDN.

Myrrh; Essential oil of ——. K. Lewinsohn. Pharm. Zeit., 1906, 51, 782.

ESSENTIAL oil of myrrh contains 1 per cent. of eugenol; meta-cresol; free acetic and palmitic acids;

pinene; dipentene; limonene; and two sesquiterpenes of the formula $C_{15}H_{24}$, one of which is probably identical with cadinene.—J. O. B.

Elaterin. J. Pollak. Ber., 1906, **39**, 3380—3382.

The elaterin used had been prepared from *Elaterium album*, so-called, the dried sap of the fruit of *Ecballium* (*Monordica*) *Elaterium*. It forms handsome colourless crystals, which melt at 222°—223° C. after several crystallisations from alcohol. Analyses point to the formula $C_{20}H_{28}O_5$ or $C_{20}H_{26}O_7$. No methoxyl groups are present. It dissolves slowly in alcoholic potash. On diluting with water and extracting with ether, an amorphous product results. If acidified and extracted with ether, the residue gives water and acetic acid on distilling in a vacuum. Acetic acid is given off when elaterin is treated with cold sulphuric acid. If the resulting liquid be neutralised, there is a precipitate. The filtrate, when distilled in a vacuum, yields acetic acid. Determinations indicate the presence of only one acetyl group.—F. Shdn.

Novocaine; Characters and tests for ——. P. Lemaire. Répert. Pharm., 1906, **18**, 433—436.

Novocaine, *p*-aminobenzoyldiethylaminoethanol hydrochloride, occurs in fine white needles, m. pt. 156° C., very soluble in water; the 4 per cent. aqueous solution is optically inactive, thus differing from cocaine. A few particles of novocaine, added to 1 or 2 drops of strong cobalt nitrate solution and gently warmed, give a fine blue colour; cocaine, alypine, and stovaine react similarly. Nine c.c. of 10 per cent. zinc chloride solution give with 1 c.c. of a 5 per cent. solution of novocaine hydrochloride a precipitate of fine acicular crystals. Under similar conditions no reaction is obtained with cocaine, stovaine, or eucaine hydrochlorides; holocaine forms only droplets on the side of the tube. 0·5 c.c. of a 1 per cent. solution of novocaine, added to 1 c.c. of sodium hypobromite reagent, gives in the cold, an orange precipitate, becoming red on heating. Alypine, cocaine, stovaine, and tropacocaine give no coloration. Two or 3 drops of 2 per cent. solution of ammonium iron alum added to 2 or 3 c.c. of 1 per cent. novocaine solution, give no violet colour as with subuctine and nirvanine, nor a red brown as with orthoform. Gold chloride solution (1 per cent.) gives an immediate brown precipitate with novocaine; with cocaine and tropacocaine hydrochlorides, and with alypine and stovaine, the precipitate is whitish. Like cocaine and its allied bases, novocaine gives a precipitate, in the cold, with potassium permanganate.—J. O. B.

Nandina domestica; Hydrocyanic acid from the leaves of four varieties of ——. J. Dekker. Apoth.-Zeit., 1906, **21**, 843.

The aqueous distillate from the fresh leaves of *Nandina domestica*, var. *fructu albo*, contained hydrocyanic acid equivalent to 0·12 per cent. of the material. *Nandina domestica*, var. *fructu rubro*, gave 0·147 per cent.; the var. *major*, 0·070 per cent.; and var. *angustifolia*, 0·070 per cent. Acetone was also present in the distillates. Eijkman has previously recorded the presence of berberine and of the amorphous alkaloid nandinêne, $C_{19}H_{19}NO_4$, in the root-bark.—J. O. B.

Carbon bisulphide; Spontaneous ignition of —— *on pouring.* Pape. Rev. Scientif.; through Rev. Pharm., 1906, **24**, 213.

A case of spontaneous ignition of carbon bisulphide is recorded, when the liquid was being transferred from a container to a glass carboy, by means of a metal funnel. The operation was being conducted in the open air, and about 100 metres from any naked flame. The ignition is attributed to an electric discharge, excited by the friction of the falling liquid on the iron funnel, which, resting on the glass mouth of the carboy, was completely insulated. The weather at the time was very hot and dry. Similar cases of spontaneous ignition have occurred when carbon bisulphide has been filled into iron drums, for transport. This has usually also been attributed to electrical discharge, but T. Trapl points out that this may not be the only cause. The oxidation of ferrous sulphide may cause sufficient rise of temperature to ignite the bisulphide. This has been shown to be the cause of an explosion of distillation products from heavy tar oils. The danger may be avoided by filling the drums with carbon dioxide, or other inert gas, before introducing the inflammable liquid.—J. O. B.

Sodium chloride; Organo-sols and -gels of ——. C. Paal and G. Kühn. Ber., 1906, **39**, 2859—2862.

By the interaction of sodium ethyl malonate and ethyl chloroacetate in benzene solution, sodium chloride and the organic condensation product are formed, but the former remains dissolved as organosol, giving rise to an opalescent orange-coloured solution. Petroleum ether precipitates this and the absorbed organic compound in an amorphous state, the fresh precipitate being entirely soluble in benzene, though containing 58 per cent. of sodium chloride. Similar results are obtained on carrying out the reaction in ligroïn or xylene; in the latter case the solution on standing deposits the organogel of sodium chloride as an orange transparent jelly. On adding acetyl chloride diluted with benzene to sodium ethylmalonate, a similar orange opalescent solution is at first produced, following which a voluminous deep orange jelly of organogel is obtained; this, in the dry state, contains as much as 87 per cent. of sodium chloride.—E. F. A.

Sodium bromide; Organo-sols and -gels of ——. C. Paal and G. Kühn. Ber., 1906, **39**, 2863—2866. (See preceding abstract.)

Sodium ethylmalonate and ethyl bromoacetate react in benzene to form the soluble organosol which is precipitated by petroleum ether and then dissolves completely in benzene; this contains 80 per cent. of sodium bromide. The gel is obtained as a voluminous orange-yellow jelly. On condensing with acetyl bromide a rose-coloured amorphous gel is precipitated. The organosol of sodium bromide is less stable than that of the chloride and therefore more easily converted into the corresponding gel; traces of water rapidly cause the partial conversion into crystalline salt. The authors were unsuccessful in obtaining the corresponding sodium iodide sol or gel; crystalline compounds always resulted from the interaction of sodium ethylmalonate with iodine, ethyl iodide, or *p*-iodoethylpropionate, either in benzene or xylene solution.—E. F. A.

Permanganate solution; Titration with alkaline ——. [*Determination of formic and nitrous acids.*] E. Rupp. XXIII., page 1070.

Ether; Exemption from duty of sulphuric —— *in Holland.* Bd. of Trade J., Oct. 18, 1906. [T.R.]

The *Nederlandsche Staatscourant* for October 2, contains the text of a decree, dated September 18, authorising the importation, duty free, of sulphuric ether for use in the manufacture of incandescent mantles.

English Patents.

Emulsions of mercury or other conducting substances; Process and apparatus for making ——. E. Lederer. Eng. Pat. 18,513, Sept. 13, 1905. XI*A*., page 1052.

Saturated compounds; Conversion of unsaturated into ——. C. Dreymann, Turin, Italy. Eng. Pat. 19,988, Oct. 3, 1905.

See Fr. Pat. 358,212 of 1905; this J., 1906, 224.—T. F. B.

Aldehydes; Manufacture of ——. E. Spurge, Witham. From E. C. Spurge, Niagara Falls, U.S.A. Eng. Pat. 21,814, Oct. 26, 1905.

The process described in U.S. Pat. 829,360 of 1906 (this J., 1906, 909) for producing vanillin from isoeugenol is applied also to the oxidation of other aromatic compounds with the side chain, $-CH{:}CH.CH_3$ (*e.g.*, isosafrol and anethol), to aldehydes; more water should be present in these latter cases than in the oxidation of isoeugenol, since the bisulphite derivatives of heliotropin and anisaldin are much less soluble than that of vanillin, and the condensation product is therefore liable to become an effect.—T. F. B.

Therapeutical preparations containing formic aldehyde. P. Rosenberg, Berlin. Eng. Pat. 2662, Feb. 3, 1906.

This therapeutical preparation is composed of a chemical combination of 5 mols. of formaldehyde with one of milk sugar. The product is a solid soluble in water, acetone, or alcohol. It has no corrosive action on the mucous membranes. It is broken up into formaldehyde and milk sugar by decomposing agents, including those present in the human body. It is prepared by mixing a solution of formaldehyde, or trioxymethylene, with the amount of milk sugar indicated by the above composition. The mixture is heated in a vacuum at a temperature of 60°—70° C., and then evaporated to dryness in the open at a temperature not exceeding 70° C.—F. Shdn.

United States Patents.

Acetylene and chlorine; Process of making compounds of ——. J. H. Lidholm, Alby, Sweden. U.S. Pat. 831,725, Sept. 25, 1906.

See Fr. Pat. 358,146 of 1905; this J., 1906, 197.—T. F. B.

Pinene; Derivative of ——, *and process of making same.* N. Thurlow, Niagara Falls, N.Y., Assignor to the Portchester Chemical Co., Port Chester, N.Y. U.S. Pat. 833,095, Oct. 9, 1906.

Pinyl oxalate, b. pt. 157°—160° C. at 680 mm. vacuum, is prepared by heating turpentine with oxalic acid at a temperature below 120° C., distilling the reaction product at 78°—82° C. under a vacuum of half an atmosphere, and afterwards distilling the residue with steam until 85—90 per cent. have come over. The distillate is an oily mass (sp. gr., 0·930—0·935 at 20° C.) containing pinyl oxalate, having a harsh, unpleasant odour, and becoming brown on exposure to the air. On heating, it decomposes into camphor, carbon monoxide, and water; when heated with water, it yields oxalic acid and hydrocarbons.—A. S.

German Patents.

Camphor; Process for the purification of ——. A. Hesse. Ger. Pat. 164,507, May 19, 1904.

The patentee has discovered that camphor is soluble in dilute sulphuric acid. The solution of the crude camphor is warmed to decompose impurities, and the latter or their decomposition products are removed by decanting, filtering, &c. The camphor is afterwards precipitated from the solution by dilution with water, or by extraction with suitable solvents. The process is stated to be specially useful for the purification of artificially prepared camphor, as the mixture of camphor with borneol or isoborneol containing small quantities of manganese and chromium compounds can be treated directly. The camphor is obtained from the sulphuric acid solution, by diluting with water, as a white pulverulent precipitate. —A. S.

Salts of organic acids; Process for preparing alkali —— from the corresponding acid nitriles and amides. Deutsche Gold- und Silber-Scheide Anstalt, vorm. Rössler. Ger. Pat. 169,186, July 9, 1903.

Acid amides or nitriles are converted into the alkali salts of the corresponding acids by treatment with calcium hydroxide, and an alkali salt of an acid, the calcium salt of which is with difficulty soluble in neutral or alkaline solutions. By thus avoiding the use of free alkali hydroxide, the process becomes cheaper, whilst, at the same time, the products are said to be of greater purity, the calcium salt carrying down the impurities with it. —T. F. B.

Alcohols; Process for preparing symmetrical dihalogen derivatives of tertiary ——, *of the formula* $R.C(OH)(CH_2.halogen)_2$. Farbenfabr. vorm. F. Bayer and Co. Ger. Pat. 168,941, Jan. 27, 1905.

By the action of alkyl- or aryl-magnesium halides on symmetrical dihalogenated acetone derivatives, double compounds are obtained, which are readily decomposed by water or acids, producing the corresponding dihalogenated tertiary alcohols, $R.C(OH)(CH_2X)_2$, R representing an aromatic radical, and X, halogen. β-Naphtyldichlorhydrin, β-phenyldichlorhydrin, β-ethyldiiodohydrin and similar compounds can be prepared by this process. —T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 1003.)

Sodium sulphite solutions; Stable ——. W. Weissenberger. Eder's Jahrbuch. Brit. J. Phot., 1906, 53, 829—830.

Two samples of a 5 per cent. sodium sulphite solution, one of which also contained 2 per cent. of mannitol, were kept for 14 days, at the end of which time each was utilised for development with amidol; the one containing mannitol possessed strong developing properties, whilst the other was useless. A similar solution (containing mannitol), after keeping for three months in a corked bottle, contained 1·2 per cent. of sulphite; increasing the quantity of mannitol to 4 per cent. gave no increase of stability. Solutions prepared with anhydrous sulphite were more stable, a solution of 25 grms. per litre, containing 4 per cent. of mannitol, still containing 1·59 per cent. after three months and 0·65 per cent. after six months. Glycerol and isobutyl alcohol possess similar preservative properties for sulphite solutions, but not quite so marked as those of mannitol. Finally, it was found that a concentrated solution of sodium sulphite (anhydrous sulphite, 25 grms.; mannitol, 2 grms.; water, 100 c.c.) was very stable, only losing 1 per cent. of sulphite in three months.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

(*Continued from page* 1006.)

Explosion; Circumstances attending an ——, *in the Press House and Incorporating Mills, which occurred at the factory of the Sedgwick Gunpowder Co., Ltd., at Sedgwick near Kendal, Westmorland, on June 23, 1906.* By Major A. Cooper-Key, H.M. Inspector of Explosives.

During a severe thunderstorm, which passed over the factory in question, the cake press house and four incorporating mills exploded. The explosions were undoubtedly due to lightning, and they all took place at the same instant, and there would appear to have been at least three separate strokes from the same flash. Of these three strokes, *viz.*, those which struck a poplar tree in front of one of the mills and the copings of another mill respectively, could not have been due to surging, side-flash, or other inductive effect, as the material struck was in each case non-conducting, but it is not improbable that the presshouse was blown up by an induced current or flash in the interior of the building. There is, therefore, evidence of the somewhat rare phenomenon of a divided flash striking simultaneously two unprotected objects nearly 100 yards apart, whilst at the same moment, a third object, the press house, 40 yards from the nearer of the other two, and protected by conductors, was separately exploded either directly or indirectly by a portion of the same flash. A description is given of the [illegible]

of lightning conductors recommended by Major Cardew for explosives factories in South Africa, where thunderstorms are so frequent and severe. The following modification of that system is recommended as securing a reasonable degree of safety, in the case of explosives factories in Great Britain. Two or more well-earthed conductors should be raised as high as practicable on poles standing a yard or two away from the actual building. These should be connected near their upper terminals by means of barbed-wire cables. The "finials" should consist of as many points as possible, and all joints should be made thoroughly good mechanically, and soldered in addition. If the conductors are actually in contact with the building, there is an increased risk of a portion of the flash seeking an alternative path through some metal inside the building, with disastrous results, many, if not most, building materials being better conductors than dry air, and, moreover, sharp bends are not so easily avoided as when separate poles are used. Internal masses of metal should be thoroughly well connected to each other and to earth, and should be situated at as great a distance as practicable from the conductors. All external metal, such as rain gutters, lead flashing, iron door plates, &c., should be connected to the conductors or otherwise thoroughly earthed. The press house under consideration in the report, was protected by two conductors of copper tape of the usual weight, one at each end of the building, connected along the ridge and well earthed in wet soil. Neither the metal inside the building nor the pressure feed pipe leading into it from the pump were connected to earth, and the conductors had not been tested for nearly three years. Moreover, the copper tapes were attached to the building instead of being raised on poles some little distance away. The building was, therefore, exposed to danger from all the sources mentioned above.

—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 1010.)

APPARATUS, &c.

GERMAN PATENT.

Lubricants; Apparatus for testing ——. J. Walther. Ger. Pat. 171,181, May 29, 1904.

THIS patent relates to apparatus of the type in which a vertical, loosely mounted disc is pressed against a rotating disc with the interposition of a film of the lubricant. The weight or power necessary to prevent the rotation of the loose disc is a measure of the friction. In order to allow of changing the material of the friction-discs, and of working at higher temperatures than that of the atmosphere, the apparatus is enclosed in an open double-walled cylinder, and the friction-discs are so mounted that they can be exchanged for others when desired.—A. S.

INORGANIC—QUALITATIVE.

Oxygen; A test for ——. A. C. Christomanos. Verh. Ges. Deutsch. Ntf. u. Aerzte, 1905, II. Teil., I. Hälfte, 76—77. Chem. Centr., 1906, 2, 1139—1140.

IF phosphorus tribromide be allowed to act upon copper salts, especially upon copper nitrate, solid or in solution, and, after cooling, the mixture be shaken with ether, a liquid is obtained, which forms an extremely sensitive reagent for the detection of oxygen, either gaseous or dissolved in alcohol, ether, &c., or the oxygen of hydrogen peroxide. With the colourless reagent prepared with copper nitrate solution, the presence of a trace of oxygen causes the upper ethereal layer to become green, and the lower layer purple-red; the colorations soon disappear, but are formed again on exposure to fresh oxygen. The reagent prepared with solid copper nitrate has a yellowish-green tint; it becomes coloured an intense green in presence of oxygen, the coloration being deeper and more persistent than that obtained when copper nitrate solution is used. The reagent contains cuprous bromide and phosphorous acid, which are oxidised in presence of oxygen.

The reagent can also be used for the detection of acetylene.—A. S.

Phosphorus; Investigations on ——. A. Siemens. VII., page 1044.

INORGANIC—QUANTITATIVE.

Potassium; Quantitative determination of ——. R. Pajetta. GAZ. Chim. Ital., 1906, 36 [2], 150—156.

THE author has examined the method for the determination of potassium proposed by Tarugi (this J., 1904, 882), and finds that potassium persulphate is more soluble in water and in solutions of potassium or sodium sulphate than stated by that author. The solubility of potassium and sodium persulphates in water is increased by the presence of sodium sulphate, and diminished by the presence of potassium sulphate. Since even in the simplest case, namely, the determination of potassium in potassium sulphate, by Tarugi's method, sodium sulphate is formed as a reaction product, accurate results cannot be obtained.—A. S.

Hydrofluosilicic acid; Note on the titration of ——. N. Sahlbom and F. W. Hinrichsen. Ber., 1906, 39, 2609—2611.

THERE is a difference of opinion in the literature whether hydrofluosilicic acid can be titrated as a monobasic acid requiring 6 mols. of potassium hydroxide (Offermann's method), or as a dibasic acid requiring 2 mols. (Weiss's method). Treadwell advises titration in presence of alcohol in the latter case, whilst Penfield makes use of an indirect method by treating the silicon fluoride with a 50 per cent. alcoholic solution of potassium chloride. The authors find that, inasmuch as hydrofluosilicic acid is a strong acid, the nature of the indicator used is of minor importance, but that, in presence of alkaline solutions, i.e., of hydroxyl ions, the hydrofluosilicic acid is hydrolysed easily into silicic acid and hydrogen fluoride. It can, thus, only be titrated as a dibasic acid when removed from the further action of the hydroxyl ions, e.g., by precipitation with alcohol as insoluble potassium or barium salt. On heating, the hydrolysis is much accelerated, and the acid can then be directly titrated with sodium hydroxide as a monobasic acid according to the equation:—

$$H_2SiF_6 + 6NaOH = 6NaF + Si(OH)_4 + 2H_2O.$$

The thermal springs of the Kaiserbad, in Aachen were found to contain 0·0008 grm. of fluorine per litre.

ORGANIC—QUALITATIVE.

Cholesterol and phytosterol; Method for the separation of ——. A. Windaus. Chem.-Zeit., 1906, 30, 1011.

The author is of opinion that a process for separating cholesterol and phytosterol can be based on the great difference in solubility of the dibromides of these alcohols in mixtures of ether and glacial acetic acid. A mixture of 40 c.c. of ether and 66 c.c. of glacial acetic acid dissolves only 0·25 grm. of cholesteryl dibromide, and this slight solubility is further reduced by very small additions of water. Phytosteryl dibromide is much more soluble in the ether-acetic acid solution, and separates only after the addition of considerable quantities of water. The dibromides are easily prepared from the alcohols by dissolving the latter in 10 times their volume of ether, and treating the ethereal solution with an equal volume of a 5 per cent. solution of bromine in glacial acetic acid, allowing the mixture to stand for an hour in ice-cold water. In the case of cholesterol, a certain quantity of dibromide separates out, and this can be increased by the addition of a few drops of water. The phytosteryl dibromide does not separate unless a considerable volume of water be added. The dibromides thus obtained are easily converted into the alcohols by treatment with zinc dust or sodium amalgam; the author prefers the former method. Experiments are quoted in which a qualitative separation of the mixed alcohols was obtained.—J. A.

Butter; Detection of cocoanut oil and margarine in ——. L. Robin. XII., page 1055.

ORGANIC—QUANTITATIVE.

Silk; Weighted ——. R. Gnehm and W. Dürsteler. Färber-Zeit., 1906, 14, 218—220, 233—237, 249—253, 269—272, 286—288, 299—305.

The method most generally applicable for determining the amount of weighting in silk is the nitrogen method. The authors prefer the Kjeldahl method, the first operation consisting in digesting the silk with a mixture of sulphuric and phosphoric acids in presence of mercury. This method can, however, be replaced in many cases by the extraction process, which, in addition to being more rapid, enables the nature of the charge to be examined to a large extent.

Examination of weighted silk dyed with colours other than black.—The method proposed by Gnehm (this J., 1903, 968) of extracting with cold hydrofluoric acid gives low results generally, whilst Zell's method, involving treatment with hot 5 per cent. hydrochloric acid (this J., 1903, 825), is also unreliable, the results being too high. The best method is found to be to extract the silk twice, for 15 minutes, with 1 to 2 per cent. hydrofluoric acid at 50°—60° C., using a platinum thimble. Extraction with hydrofluosilicic acid appears to be always incomplete, and was therefore rejected. Silk weighted with tin phosphate-silicate may be advantageously treated for half an hour with hydrogen sulphide in presence of dilute hydrochloric acid, at 70°—80° C., then for five minutes with 4 per cent. sodium sulphydrate solution at 40°—50° C., and finally for 15 minutes with 2 per cent. sodium carbonate solution, at 60°—70° C.; a pure silk fibroin remains after this extraction. If the silk has also been weighted with an aluminium compound, the above extractions must be repeated, since the first extraction will only remove about three-fourths of the charge. Ordinary mineral weightings can also be satisfactorily determined by treatment with oxalic acid solution at 70° C., followed by treatment with dilute sodium carbonate solution.

Examination of weighted black silks.—Black silks in which the weighting consists entirely of tin phosphate, can be completely extracted by heating with 1—2 per cent. hydrofluoric acid (or 3—5 per cent. oxalic acid), and then with 2 per cent. sodium carbonate solution; both these methods are useless when iron is present. By successive extractions with hydrogen sulphide in 1 per cent. hydrochloric acid solution, 4 per cent. sodium sulphydrate, and 2 per cent. sodium carbonate solution, the charge can be practically completely extracted from all black silks, without material deterioration of the fibre; the results are usually somewhat low, but are sufficiently accurate for practical purposes. (See also this J., 1903, 622.)

Determination of constituents of mineral weightings.—It is recommended that the charge be extracted from the silk with hydrofluoric acid, or, preferably, oxalic acid, and the acid extract and ash remaining after ignition of the residue, examined. The hydrogen sulphide extraction method is of little value for this purpose. Silica is determined in the ash after extraction with oxalic acid in the usual manner. Tin can best be determined by electrolytic precipitation from the oxalic acid extract. Hydrofluoric acid extraction is not suitable for determining the silica in the charge, but can be used for determining all other mineral weighting materials.—T. F. B.

Chromed hide powder question; The ——. F. Kopecky. XIV., page 1058.

"Glucose"; Report on the determination of —— *by the volumetric method.* A. Watt. Internat. Sugar Jour., 1906, 8, 502—506.

The author is inclined to attribute the wide differences between the estimations of "glucose" in beetroot sugar by British and Continental chemists respectively to differences of method, the volumetric process (which, as usually worked, is liable to many sources of error) being used by the former, whereas the gravimetric process is used on the Continent. In the volumetric process, variations in the conditions of working, cause serious errors; the greatest error thus introduced (which may amount to 20—150 per cent. of the "glucose") is due to the presence of sucrose. The author recommends the compilation of tables of correction similar to those used for the gravimetric process, and, in the meantime, he suggests that the volumetric results should be corrected by standardising the Fehling solution with solutions containing sucrose and invert sugar, in the proportions present in the samples under investigation. —L. E.

"Crude fibre"; Determination of cellulose, lignin and cutin in ——. J. König. Z. Unters. Nahr. u. Genussm., 1906, 12, 385—395.

"Crude fibre," whether obtained by the well-known process of Henneberg and Strohmann or by the modified process of the author [hydrolysis of the hemicelluloses by sulphuric acid in presence of glycerol] is a mixed product containing, in addition to the more resistant celluloses, lignin, and the complex esters known under the general names of cutin and suberin. In order to determine these constituents of the complex, the "crude fibre" is digested in the cold with hydrogen peroxide in presence of aqueous ammonia. The treatment is continued for a long time, with successive additions of hydrogen peroxide until the residue is colourless. The lignin is oxidised by this treatment, and is converted into soluble products. The residue, cellulose *plus* cutin, is then treated with the cuprammonium solvent, whereby the cellulose is dissolved whilst the cutin remains unattacked. The liquid is filtered in a Gooch crucible, and the residue of cutin is weighed; the cellulose is determined in the filtrate after precipitation by alcohol, and the difference between the sum of these two values and the weight of crude fibre taken, is expressed as lignin. These determinations are supplemented by combustion analyses of the respective products, from the results of which, in the case of meadow-hay, clover-hay, and various brans, the author concludes that the lignin contains 55·3—59·0 per cent. of carbon, and the cutin 60·0—75·4 per cent. of carbon. In many of the specimens examined, the cellulose separated from solution in cuprammonium was found to contain a higher percentage of carbon than the normal. This was found

to be due to the presence of methoxyl groups, the proportion of which ranged between 0·4 and 2·62 per cent., the latter number being found in the cellulose of wheat bran. This is in accordance with the observations of Cross, Bevan, and Beadle, who called attention to the presence of methoxyl groups in the cellulose from jute. The lignin portion of the "crude fibre" contains, in addition to methoxyl groups, ethoxyl and acetyl residues. The percentage of lignin in the plant increases as the vegetation develops, and this increase is more pronounced than that of the cellulose. The higher the percentage of lignin and cutin, the lower is the digestibility of the "crude fibre" or cellulose, and *vice-versa*.—J. F. B.

Crude petroleum; Determination of water in ——. E. Graefe. III., page 1035.

Permanganate solution; Titration with alkaline ——. [*Determination of formic and nitrous acids*]. E. Rupp. Z. anal. Chem., 1906, **45**, 687—692.

In certain cases oxidation by means of permanganate takes place more rapidly in alkaline than in acid solution, and the following methods are given for the determination of formic acid and nitrous acid:—

Formic acid.—A measured volume of formic acid (or formate) solution, containing not more than 1 per cent. of the acid, is placed in a stoppered flask, an excess of *N*/10 permanganate solution and 0·5 grm. of anhydrous sodium carbonate are added, and the mixture is heated in a water-bath for 30 minutes. After cooling, 75 c.c. of water, 25 c.c. of dilute sulphuric acid, and 2 grms. of potassium iodide are added, and the liberated iodine is titrated with thiosulphate solution. Each c.c. of *N*/10 thiosulphate solution corresponds with 0·0023 grm. of formic acid. The heating in the water-bath is necessary, as at the ordinary temperature the oxidation requires from six to ten hours for completion. In acid solution, the oxidation of formic acid by permanganate is not nearly completed after the lapse of ten hours.

Nitrous acid.—The oxidation of nitrous acid proceeds equally rapidly in acid and alkaline solutions but in the former there is a danger of loss of nitrous acid. The determination is carried out as in the case of formic acid except that no heating is required, the oxidation being completed in 10 minutes at the ordinary temperature. One c.c. of *N*/10 thiosulphate solution is equivalent to 0·0023 grm. of NO'_2. (See also this J., 1906, 41.)—W. P. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 1010.)

Autoxidation and oxidation by means of nitric oxide. W. Manchot. Ber., 1906, **39**, 3510—3511.

It has already been shown by the author and Herzog, that by the autoxidation of organic compounds of the type RH_2, such as oxanthranol, indigo white, hydrazobenzene, and the like, the oxygen taking part in the reaction leads to the formation of hydrogen peroxide according to the equation $RH_2 + O_2 = R + H_2O_2$. It has been found by further experiment that oxidation also takes place smoothly and with the same rapidity by the action of nitric oxide on the above compounds, and this without the production of hydrogen peroxide, the reaction being represented by the equation—

$$RH_2 + 2NO = R + H_2O + N_2O.$$

The formation of hydrogen peroxide is, in the author's opinion, due to the fact that the chain of two atoms of oxygen contained in the oxygen molecule is not split up by the reaction.—D. B.

Thiocarbamide as a solvent for gold. J. Moir. Chem. Soc. Trans., 1906, **89**, 1345—1359.

The author has previously shown (this J., 1906, 481) that gold is dissolved by acid solutions of thiocarbamide, especially in presence of suitable oxidising agents. From the solutions of gold containing hydrochloric acid and sulphuric acid respectively, two new complex salts have since been isolated, for which the author proposes the formulæ

$$2[C_2H_6N_4S_2AuCl],2CH_4N_2S \text{ and}$$
$$(C_2H_6N_4S_2Au)_2SO_4,2CH_4N_2S.$$

The complex chloride can also be obtained by the action of thiocarbamide on gold-potassium chloride solution. *s*-Diphenyl- and diacetyl-thiocarbamide have no solvent action on gold; hence it would appear that the activity of thiocarbamide itself depends upon its isomerisation to the compound, $NH{:}C(NH_2).SH$, the hydrogen of the SH group being replaceable by gold. The author is of opinion that most of the so-called addition compounds of thiocarbamide and salts of the heavy metals (compare Emerson Reynolds, Annalen, 1869, **150**, 255) are constituted similarly to the compounds described above, and thus contain less hydrogen than is indicated by the accepted formulæ.—A. S.

Serine; Resolution of racemic —— *into optically active components.* E. Fischer and W. A. Jacobs. Ber., 1906, **39**, 2942—2950.

Serine, the simplest hydroxyamino acid occurring among the decomposition products of proteids, has been known hitherto only in the racemic form. The *p*-nitrobenzoyl derivative has been completely resolved by means of the quinine salt into the isomeric optically active nitrobenzoyl-serines which, when heated with hydrogen bromide, are converted into the corresponding active serines. These have the rotation $[\alpha]_D = +6{\cdot}87$, and $[\alpha]_D = -6{\cdot}83$ respectively in water, and are otherwise very similar in properties. *d*-Serine tastes distinctly sweet, *l*-serine is less so though still appreciably sweet and has a peculiar after-taste. *l*-Serine is probably the naturally occurring form, as its methyl ester yields an anhydride identical with a substance isolated from the decomposition products of silk fibroin. The authors have also resolved *iso*-serine and diaminopropionic acid.—E. F. A.

Exhibitions; Committee on International ——. Times Oct. 25, 1906.

The president of the Board of Trade has appointed the following gentlemen to be a committee to make inquiries and to report with reference to the participation of this country in great international exhibitions:—Sir A. E. Bateman, K.C.M.G., chairman; Mr. A. Wilson Fox, C.B.; Mr. C. A. Harris, C.B., C.M.G.; Mr. Algernon Law; Sir James Kitson, Bart., M.P.; Mr. Malcolm Ramsay, C.B.; Sir Swire Smith; Mr. S. J. Waring. Mr. J. F. Wintour, of the Board of Trade, will act as secretary to the committee. The terms of reference to the committee are:—"To inquire and report as to the nature and extent of the benefit accruing to British arts, industries, and trade from the participation of this country in great international exhibitions; whether the results have been such as to warrant His Majesty's Government in giving financial support to similar exhibitions in future; and, if so, what steps, if any, are desirable in order to secure the *maximum* advantage from any public money expended on this object."

New Book.

Ammonia and its Compounds. By J. Grossmann, M.A., Ph.D. Harper & Brothers, 45, Albemarle Street, London, W.; and New York. 1906. Price 2s. 6d. net.

Small 8vo volume, containing 127 pages of subject matter with seven illustrations, 16 additional pages devoted to tables of specific gravity, comparative table of hydrometer degrees (Baumé and Twaddell), with corresponding specific gravities. Finally, the alphabetical index. The subject matter is subdivided as follows: I. Ammonia. II. Concentrated gas liquor. III. Liquor ammonia. IV. Liquid ammonia. V. Ammonium carbonates. VI. Ammonium sulphate. VII. Waste gases and liquors from the sulphate manufacture. VIII. Ammonium chloride. IX. Ammonium nitrate. X. Ammonium phosphate. XI. Ammonium sulphides. XII. Ammonium fluorides. XIII. Ammonium sulphocyanide and ferrocyanide. XIV. Ammonia recovery from spent oxide.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—6d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1s. each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

DECENNIAL INDEX, 1896—1905.

IMPORTANT NOTICE.

The Hon. Treasurer is prepared to receive subscriptions for the Decennial Index (1896—1905). The Authors' Names portion is now in the press and will be issued early in the new year; and the subject-matter portion will follow as soon as possible afterwards. The price is 10*s.* for the whole Index, or 11*s.* ($2.75) post free.

Copies of the Collective Index (1881—1895) may be had at the same price.

Cheques on members' own bankers, or money orders, payable at the G.P.O., London, should be made payable to Samuel Hall, and sent to the Hon. Treasurer, East London Soap Works, Bow, E., with the signed fly-leaf of a notice which will be sent out with the ordinary subscription notice, and to any others who make application for it.

SUBSCRIPTIONS OF MEMBERS ABROAD.

IMPORTANT NOTICE.

Members are reminded that the subscription of 25*s.* ($6.16) for 1907 should be sent to us to reach the Hon. Treasurer early in the New Year, so as to ensure continuity in the receipt of the Society's Journal.

[illegible]

"INDUSTRIAL DISEASES COMMITTEE."

With reference to a notice which appeared in the November 15th issue of the JOURNAL (p. 1035), announcing the appointment of a Departmental Committee "to inquire and report what diseases and injuries, other than injuries by accident, are due to industrial occupations, are distinguishable as such, and can properly be added to the diseases enumerated in the Third Schedule of the Workmen's Compensation Bill, 1906," members who desire to assist the Committee by tendering evidence are requested to communicate with the Society.

List of Members Elected.

Nov. 22, 1906.

Bracegirdle, Harold W., 1, Mytton Street, Hulme, Manchester, Chemist.

Breckenridge, John R., American Agricultural Chemical Co., Carteret, N.J., U.S.A., Chemist.

Brown, Harry F., c/o E. I. du Pont Co., Wilmington, Del., U.S.A., Chemist.

Chapman, Arthur J., Bannockburn, Shooters Hill, Church End, Finchley, N., Analytical Chemist.

Church, Sumner R., c/o Barrett Manufacturing Co., 17, Battery Place, New York City, U.S.A., Chemical Engineer.

Gandil, Lewis C., Chemical Laboratory, [illegible]

[illegible]

Dixon, E. Oliver, Alan Drive, Hale, Cheshire, Fruit Preserver.
Dooley, Edward J., 68, Hazel Street, Boston, Mass., U.S.A., Dealer in Animal Oils.
Frohnser, Edward, jun., c/o Standard Table Oil Cloth Co., Youngstown, Ohio, U.S.A., Manager.
Gillies, Donald B., Tonopah, Nevada, U.S.A., Mining Engineer.
Gullins, Percy, Merrimac Manufacturing Co., Lowell, Mass., U.S.A., Print Works Superintendent.
Hancock, H. Irving, Blue Point, N.Y., U.S.A., Chemist.
Haworth, Arthur E., 2, Carlton Terrace, Hornsea, East Yorks, Works Chemist.
Heimer, Charles, c/o Messrs. H. & A. Saunders, Eclipse Building, King Street, Toronto, Canada, Assistant Manager.
Howland, Geo. W. 293, Dufferin Street, Toronto, Canada, Manager.
Hutton, James S., 61, Plymouth Road, Malden, Mass., U.S.A., Chemist.
Knudsen, Kristian H., 226, Willoughby Avenue, Brooklyn, N.Y., U.S.A., Chemist.
Kreis, Dr. Paul, 60, Nauclerstrasse, Tuebingen, Germany, Chemist.
Maguire, Peter, Hamer House, Rochdale, Lancs., Chemist and Colourist.
Nielsen, Dr. Carl, 107, West 72nd Street, New York City, U.S.A., Chemist.
Pelle, Henry, Millburn House, Newcastle-on-Tyne, Colliery Owner.
Peschen, Arthur G., Standard Chemical Co., Ltd., Toronto, Canada, Chemical Manufacturer.
Porter, John J., Box 551, Staunton, Va., U.S.A., Chemist and Metallurgist.
Raffi, Dr Albert K., 1377, Michigan Street, Buffalo, N.Y., U.S.A., Chemist.
Ranck, Samuel H., Ryerson Public Library Building, Grand Rapids, Mich., U.S.A., Librarian.
Rees, Walter James, c/o Chance Bros. & Co., Ltd., Smethwick, near Birmingham, Glass Works Chemist.
Scott, Alex. C., Davington House, Faversham, Kent, Assistant Manager (Cotton Powder Co., Ltd.).
Shadbolt, Fredk., c/o The South Metropolitan Gas Company Chemical Works, East Greenwich, S.E., Chemical Engineer and Manager.
Shuttleworth, E.B., 220, Sherbourne Street, Toronto, Canada, Chemist.
Steiger, Robert R., 112, Charles Street, Lowell, Mass., U.S.A., Instructor in Dyeing.
Smith, Irwin J., P.O. Box 506, Troy, N.Y., U.S.A., Salesman.

,, 6601 (1906). Blass. *See under* XII.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 24,008. Hirschberger, Mason, and Levinstein, Ltd. Safraninones and reddish sulphurised dyestuffs therefrom. Oct. 29.
,, 24,091. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of *p*-nitrodiphenylamine or homologues or derivatives thereof. Oct. 29.
,, 24,092. Ges. f. Chem. Ind. in Basel. Manufactur of a red, vat-dyeing dyestuff from salicylthio acetic acid. [Ger. Appl., Nov. 4, 1905.]* Oct. 29.
,, 24,429. Newton (Bayer und Co.). Manufacture of anthracene derivatives. Nov. 1.
,, 24,518. Bloxam (Act.-Ges. f. Anilinfabr.). *See under* XX.
,, 24,553. Thorpe. Manufacture of diamidonaphthalene and derivatives thereof. Nov. 2.
,, 24,826. Uhlmann. Manufacture of sodium salts of aromatic sulphonic acids. [Ger. Appl., Nov. 5, 1905.]* Nov. 5.
,, 25,193. Lake (Chem. Fabr. Griesheim-Elektron). Manufacture of yellow monoazo dyestuffs.* Nov. 8.
,, 25,493. Imray (Soc. Chem. Ind. in Basle). Manufacture of monoazo dyestuffs which can be chromed. Nov. 12.
,, 25,639 Crutch. *See under* III.
,, 25,847. Lake (Chem. Fabr. Griesheim-Elektron). Manufacture of black mordant azo dyestuffs.* Nov. 15.
,, 25,889. Wells. Production of aniline dyes. Nov. 15.
,, 25,977. Johnson (Badische Anilin und Soda Fabrik). Manufacture of new diphenylamine compounds and colouring matters therefrom.* Nov. 16.
[C.S.] 7273 (1906). Ransford (Cassella und Co.). Preparations of sulphine colours. Nov. 7.
,, 9700 (1906). Imray (Meister, Lucius, und Brüning). Manufacture of phenylglycine or its homologues. Nov. 21.
,, 10,506 (1906). Schrottky. Manufacture of substances suitable for use in the manufacture of indigo. Nov. 7.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 24,303. Pering. *See under* XIX.
„ 24,677. Gaydet. Apparatus for treating with liquids yarns in the form of cops, bobbins, and the like.* Nov. 3.
„ 24,708. Mainprice. Treating silk waste preparatory to spinning. Nov. 5.
„ 24,724 and 24,725. Pickles and Pickles. Bowls or rollers used in apparatus for schreinering, calendering, embossing, and the like. Nov. 5.
„ 24,791. Kenyon. Bleaching and dyeing cotton sliver. Nov. 5.
„ 25,248. Ainley. Machines for washing and scouring fabrics. Nov. 9.
„ 25,445. Pickles and Pickles. Dyeing and mercerising fabrics. Nov. 12.
„ 25,781. D'Izoro. Cops and bobbins, dyeing and bleaching machines. Nov. 15.
„ 25,942. Heaton. Preparation for use in sizing yarn. Nov. 16.
„ 25,971. Ransford (Cassella und Co.). Manufacture of multi-coloured fabrics. Nov. 16.
[C.S.] 16,159 (1905). Quackenbos. Cleaning wool and recovering the grease and the solvent used. Nov. 21.
„ 23,050 (1905). Klug. Dyeing apparatus. Nov. 21.
„ 23,345 (1905). Ickringill. Sterilisation of wool, cotton, rag, hair, &c. Nov. 21.
„ 1939 (1906). Abel (Act.-Ges. f. Anilinfabr.). Dyeing acetylated cellulose or artificial silk made therefrom. Nov. 21.
„ 9710 (1906). De Caudemberg. Manufacture of fibrous agglomerates. Nov. 7.
„ 13,005 (1906). Ker. Thin leaf or fabric, and method of making same. Nov. 14.
„ 19,182 (1906). Richter. Apparatus for the wet treatment of fabrics. Nov. 21.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

[C.S.] 4486 (1906). Salomon. *See under* IX.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 24,101. Johnson (Chem. Fabr. Griesheim-Elektron). Manufacture of a dry chlorinated compound of lime. Oct. 29.
„ 24,134. Sisson. Hydrated carbonate of magnesium and its production. Oct. 30.
„ 24,144. Crossley and Rigby. *See under* II.
„ 24,447. British Thomson-Houston Co. (Allgem. Elektricitäts Ges.). *See under* XI.
„ 25,404. McTear. Manufacture of salt. Nov. 10.
„ 25,435. Trobridge. *See under* I.
„ 25,547. Williams and Fenner. Saturators for use in the manufacture of ammonium sulphate. Nov. 13.
„ 25,605. Cunnington. Manufacture of nitrogen compounds from atmospheric nitrogen. Nov. 13.
„ 25,813. Radcliffe. Treatment of spent liquor. Nov. 15.
„ 25,864. Kuzel. Production of colloidal elements. [Ger. Appl., Dec. 12, 1905.]* Nov. 15.
„ 25,928. Grossmann. Treatment of ammonia liquors. Nov. 16.
„ 25,976. Tyers, Hedley, and The United Alkali Co., Ltd. Treatment of sulphuretted hydrogen or gases containing sulphuretted hydrogen for the obtainment of sulphur therefrom. Nov. 16.
„ 25,978. British Thomson-Houston Co. (General, Electric Co.). Production of boron. Nov. 16.
„ 26,039 Glover and Glover. Revivifying oxide of iron. Nov. 17.
[C.S.] 1650 (1906). Wetter (Wülfing). Manufacture of black oxide of iron. Nov. 14.
[C.S.] 3980 (1906). Det Norske Aktieselskab f. Elektrokem. Ind., and Halvorsen. Production of concentrated nitric and sulphuric acids from nitrosulphonic acid and nitrous sulphuric acid. Nov. 7.
„ 7478 (1906). Fairweather (Beaver and de Nordenflycht). Dissolving plant for the recovery of sodium nitrate from caliche. Nov. 14.
„ 9621 (1906). Soc. Franç. La Norgine. Extraction of iodine from liquids containing iodine compounds. Nov. 14.
„ 11,979 (1906). Von Foregger. Means for generating oxygen. Nov. 7.
„ 11,981 (1906). Brindley. Composition for use in generating oxygen. Nov. 21.
„ 12,246 (1906). Jaubert. Preparation of oxygen by decomposition of oxygenated salts. Nov. 7.
„ 19,718 (1906). Toelle. Production of basic sulphate of lead. Nov. 21.
„ 19,732 (1906). Kronen. Production of basic lead salts insoluble in water. Nov. 7.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 24,272. Murray. Kilns for firing pottery, porcelain, bricks, &c. Oct. 31.
„ 24,589. Moir. Separating solids from water in china clay and similar materials by electrolysis. Nov. 3.
[C.S.] 12,554 (1906). Atkinson and Smith. Enamelling or glazing metallic or other surfaces. Nov. 7.
„ 18,663 (1906). Marks (Colburn). Production of sheet glass. Nov. 14.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 24,256. Kochmann and Kaufmann. Manufacture of substances capable of resisting water and chemical influences. Oct. 31.
„ 24,272. Murray. *See under* VIII.
„ 24,537. British Thomson-Houston Co. (Gen. Electric Co.). Cement. Nov. 2.
„ 24,583. Haskin. Maturing and preserving wood. Nov. 3.
„ 24,701. Meadowcroft, Holgate, and Huncoat Brick and Terra Cotta Co. Manufacture of brick and tiles. Nov. 5.
„ 24,823. Assoc. Portland Cement Manufacturers, Ltd., and Gibbs. Burning lime and other substances.* Nov. 5.
„ 25,043. Hennings. Manufacture of artificial slate.* Nov. 7.
„ 25,157. Trenkler. Accelerating the hydraulic hardening of cement, &c., made from blast-furnace slag.* Nov. 8.
„ 25,416. Evans (Graaff und Co.). Freezing-proof fire-extinguishing agent.* Nov. 10.
„ 25,417. Boult (Cöln- Müsener Bergwerks Akt.-Ver.). Hardening articles made from ground slag. Nov. 10.
„ 25,621. Woerdehoff. Manufacture of facing stone.* Nov. 13.
„ 25,857. Brooks. Hydrating and cooling cement. Nov. 15.
[C.S.] 1129 (1906). Smith. Material for making red bricks, tiles, and other articles. Nov. 21.
„ 3240 (1906). Stoddart. Manufacture of filtering media from slag. Nov. 21.
„ 4486 (1906). Salomon. Production of weather-proof and non-inflammable timber, and dyeing the same. Nov. 14.
„ 4503 (1906). Johnson (Koepp und Co.). Manufacture of stucco. Nov. 7.

X.—METALLURGY.

[A.] 24,072. Vuigner. Treatment of sulphide ores of lead and zinc. Oct. 29.
„ 24,074. Vuigner. Extraction of zinc from sulphide zinc ores, more especially from ores also containing

[A.] 24,096. Rheinische-Nassauische Bergwerks- und Hütten-A.-G., Borchers, and Graumann. Direct production of zinc from zinc sulphide and utilisation of the sulphur. [Ger. Appl., Nov. 3, 1905.]* Oct. 29.
,, 24,098. Bousfield and Bousfield. Plant for steel manufacture. Oct. 29.
,, 24,234. British Thomson-Houston Co. (Allgem. Elektricitäts Ges.). Purification of tantalum. Oct. 30.
,, 24,352. Viel. Obtaining metals and alloys, particularly aluminium and silicon, from their oxides. [Fr. Appl., Oct. 31, 1905.]* Oct. 31.
,, 24,526. Moyano. Extraction of zinc in the form of oxide from inferior calamines. [Span. Appl., June 12, 1906.]* Nov. 2.
,, 24,616. Keith and Machonochie. Utilisation of waste ferruginous materials. Nov. 3.
,, 24,905. Fernan. Extraction of metals from ores.* Nov. 6.
,, 25,112. Harbord. Pig-iron manufacture. Nov. 8.
,, 25,304. Rauch. Alloy of iron. Nov. 9.
,, 25,336. Harbord. Pig-iron manufacture. Nov. 9.
,, 25,372. Angel. Burning off zinc from oxidised ores and other materials containing zinc. Nov. 10.
,, 25,489. Perreur-Lloyd and Gardner. *See under* XI.
,, 25,530. Stanley. Crushing and treating ores for the extraction of precious metal. Nov. 12.
,, 25,553. Dawes. Blast furnaces. Nov. 13.
,, 25,574. Holdsworth. Treatment of poor sulphide ores. Nov. 13.
,, 25,966. Cowper-Coles. Rendering silver non-tarnishable. Nov. 16.
[C.S.] 23,319 (1905). Beaumont. Apparatus for recovering gold from disintegrated ores. Nov. 14.
,, 23,783 (1905). Davies. Flux for treating cast iron and other metals. Nov. 7.
,, 23,977 (1905). MacIvor, Fradd, and Metals Extraction Corporation. Treatment of sulphide ores containing zinc. Nov. 21.
,, 26,813A (1905). Ashcroft. *See under* XI.
,, 1660 (1906). Rayner, and Hardy Patent Pick Co. Machine for washing coal, minerals, &c. Nov. 14.
,, 3900 (1906). Brinton. Cast manganese steel rail. Nov. 7.
,, 4107 (1906). Hadfield. Manufacture or treatment of steel. Nov. 7.
,, 16,283 (1906). Bates and Peard. Annealing metals. Nov. 7.
,, 18,134 (1906). Stolzenwald. Realising the value of material containing zinc. Nov. 14.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 24,296. Mahlke and Brion. Electric apparatus for subjecting gases to the action of arc flames. [Ger. Appl., Nov. 3, 1905.]* Oct. 31.
,, 24,447. British Thomson-Houston Co. (Allgem. Elektricitäts Ges.). Preparation of nitrogen-oxygen compounds from mixtures of nitrogen and oxygen by means of an electric discharge. Nov. 1.
,, 24,589. Moir. *See under* VIII.
,, 24,806. Ferchland. Electrodes for electrolytic purposes. [Ger. Appl., Nov. 9, 1905.]* Nov. 5.
,, 24,820. Reynolds. Electric furnaces. Nov. 5.
,, 24,985 and 24,986. Cowper-Coles. Electrolytic deposition of metals. Nov. 6.
,, 25,489. Perreur-Lloyd and Gardner. Electrolytically extracting metals from ores.* Nov. 12.
,, 25,599. Reynolds. Electric furnaces. Nov. 13.
,, 25,991 and 25,992. Maschinenfabr. Oerlikon, Wüthrich, and Stirnimann. Electric furnaces. Nov. 16.
[C.S.] 26,813A (1905). Ashcroft. Electrolysis of metallic compounds or ores. Nov. 14.
,, 2465 (1906). Hermite. Electrolytic apparatus. Nov. 7.
[C.S.] 11,675 (1906). Brindley. Fusing materials by electricity. Nov. 7.
,, 12,329 (1906). Röchling and Rodenhauser. Electric furnaces. Nov. 14.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

[A.] 24,135. Ermen. Preparation of emulsions. Oct. 30.
,, 24,822. Karsam Soap Co., Ltd., Samuel, and Lockwood. Manufacture of soap or mixtures containing soap.* Nov. 5.
,, 25,882. Pearson. *See under* XV.
,, 26,077. Johnson (Kalle und Co.). Production of a fatty substance from micro-organisms. Nov. 17.
[C.S.] 23,546 (1905). Macpherson and Heys. Detergent for use with hard or salt waters. Nov. 21.
,, 1719 (1906). Wörner. Preparation of emulsifiable matter. Nov. 21.
,, 6601 (1906). Blass. Solidifying fluid greases, tar, &c., and increasing the consistency of solid fats, resins, soaps, or the like. Nov. 21.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(*A.*)—PIGMENTS, PAINTS.

[A.] 25,700. Meeze. Method of rust-proofing iron. Nov. 14.
,, 25,959. Griffiths. Pigments. Nov. 16.
[C.S.] 22,252 (1905). Colignon. Manufacture of paint. Nov. 7.

(*B.*)—RESINS, VARNISHES.

[C.S.] 6601 (1906). Blass. *See under* XII.
,, 11,090 (1906). Elkeles and Klie. Manufacture of polishes and varnishes from resins and the like. Nov. 21.

(*C.*)—INDIA-RUBBER.

[A.] 24,787. Lesage. Elastic material and apparatus for making it. [Fr. Appl., Nov. 6, 1905.]* Nov. 5.
,, 24,969. Gentzsch. Utilisation of waste rubber. [Ger. Appl., Nov. 16, 1905.]* Nov. 6.
,, 24,970. Gentzsch. Utilisation of waste rubber. [Ger. Appl., Feb. 2, 1906.]* Nov. 6.
,, 25,735. Alexander. Manufacture of aqueous solutions of caoutchouc and the application thereof to regenerating caoutchouc. Nov. 14.
,, 25,970. Kingzett, Kingzett, and Kingzett. Preparation of substitutes for gutta-percha and india-rubber.* Nov. 16.
[C.S.] 13,493 (1906). Hopkinson and Midgley. Vulcanisation of rubber goods. Nov. 21.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

[A.] 24,189. Thompson (Kelk). Tanning, tawing, or curing hides or skins. Oct. 30.
,, 24,267. Bailey. Treatment of isinglass. Oct. 31.
,, 25,647. Eschalier. *See under* XIX.
[C.S.] 4561 (1906). Jensen. Composition for preserving leather. Nov. 14.
,, 18,004 (1906). Osborne and Schupp. *See under* XX.

XV.—MANURES, &c.

[A.] 24,492. Lehmann. Manufacture of fertilisers from animal refuse. Nov. 2.
,, 24,647. Macdonald. Manufacture of manure.* Nov. 3.

[A.] 24,901. Catto. Condensing and deodorising gases arising from fish manure drying plant. Nov. 6.
,, 25,882. Pearson. Apparatus for extracting oil from fish, fish oil, &c., for producing fertilisers. Nov. 15.
[C.S.] 17,029 (1906). Wenzel. Composition for applying to the soil to render it porous. Nov. 14.

XVI.—SUGAR, STARCH, GUM, &c.

[A.] 24,035. Steffen. Treatment of potatoes for obtaining starch and a food-stuff.* Oct. 29.
,, 25,340. Eastick. Process for making and purifying invert sugar. Nov. 10.
,, 25,860. Ost. Sugar purification. Nov. 15.
[C.S.] 13,217 (1906). Barbet. Desulphurising saccharine fruit juices. Nov. 21.

XVII.—BREWING, WINES, SPIRITS, &c.

[A.] 24,093. Fritsche. Fermenting distillery mashes. Oct. 29.
,, 24,229. Carroll. Distillery and treating of spirits.* Oct. 30.
,, 25,595. Braunbeck. Saccharification of starch in the distilling industry, and in the production of yeast.* Nov. 13.
,, 25,691. Davis. Apparatus for use in brewing. [U.S. Appl., Nov. 15, 1905].* Nov. 14.
[C.S.] 18,351 (1905). House. Process of brewing. Nov. 21.
,, 2242 (1906). Wagner. Brewing material derived from starch and analogous farinaceous materials. Nov. 14.
,, 5619 (1906). Nathan. Vessels for use particularly in the manufacture of pasteurised beer. Nov. 21.
,, 21,567 (1906). Elektrochemische Werke Ges. Process for depriving alcohols, especially ethyl alcohol, of water. Nov. 7.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(*A.*)—Foods.

[A.] 24,035. Steffen. *See under* XVI.
,, 24,082. Linzel and Bischoff. Manufacture of non-alcoholic drinks from fermented liquors. Oct. 29.
,, 24,435. Schwarz. Preservation of grape must and other fruit juices. Nov. 1.
,, 25,019. Liversedge. Manufacture of butter and butter substitutes. Nov. 7.
,, 25,750. Rasmussen. Evaporating the watery parts of milk, dissolved casein, and other liquids and semi-liquids. Nov. 14.
[C.S.] 12,424 (1906). Von Tury. Egg substitute. Nov. 2.
,, 13,217 (1906). Barbet. *See under* XVI.

(*B.*)—Sanitation; Water Purification.

[A.] 24,172. Girerd and Drapier. Purifying waste water. Oct. 30.
,, 24,945. McLean. Preparation of valuable products from sewage sludge. Nov. 6.

XIX.—PAPER, PASTEBOARD, &c.

[A.] 24,067. Newton (Bayer und Co.). Manufacture of cellulose derivatives. Oct. 29
,, 24,281. Terrell. Manufacture of collodion for incandescent mantles. Oct. 31.
,, 24,308. Pering. Manufacture of water- and fat-proof paper, cardboard, weaving-stuff, &c.* Oct. 31.
,, 25,647. Escalier. Process for strengthening cellulose and albuminoid bodies. Nov. 13.
[C.S.] 10,486 (1906). Soc. Anon. Mirabet. Sizing composition for use in the manufacture of paper. Nov. 21.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

[A.] 24,222. Reitz. Production of radio-active crystals.* Oct. 30.
,, 24,518. Bloxam (Act. Ges. f. Anilinfabr.). Manufacture of 3-aminophenyl-5-oxy-1.2-naphthimidazoledisulphonic acid. Nov. 2.
,, 24,826. Uhlmann. *See under* IV.
,, 24,830. Chem. Fabr. von Heyden, A.-G. Manufacture of isobornyl esters. [Ger. Appl., Feb. 16, 1906.]* Nov. 5.
,, 25,494. Meister, Lucius, und Brüning. Manufacture of dialkylbarbituric acids. [Ger. Appl., Nov. 28, 1905.]* Nov. 12.
,, 25,693. Crutch. *See under* III.
,, 25,718. Newton (Bayer und Co.). Manufacture of aminoacetopyrocatechin or derivatives thereof. Nov. 14.
,, 25,747. Twitchell. Process for effecting a combination between selected alcohols and fatty acids.* Nov. 14.
[C.S.] 21,757 (1905). Zimmermann (Chem. Fabr. auf actien, vorm. E. Schering). Manufacture of organic magnesium compounds. Nov. 7.
,, 239 (1906). Ellis (Merck). Manufacture of a substance from ergot. Nov. 21.
,, 18,004 (1906). Osborne and Schupp. Converting catechine into catechutannic acid. Nov. 21.
,, 21,567 (1906). Elektrochemische Werke. *See under* XVII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[A.] 24,046. Birnbaum. Photographic films. Oct. 29.
,, 24,667. Bolas. Production of photographs. Nov. 3.
,, 25,188. Stevens and Stevens. Photographic films.* Nov. 8.
,, 25,728. Husson and Bornot. Manufacture of photographic dry plates.* Nov. 14.
,, 25,869. Bloxam (Act. Ges. f. Anilinfabr.). Agent for fixing photographic images. Nov. 15.
,, 25,906. Pfenninger. Emulsion for photographic and like purposes.* Nov. 16.
[C.S.] 23,109 (1905). Rieder. Production of photographic prints. Nov. 21.
,, 5109 (1906). Beaumont. Production of coloured photographs. Nov. 21.
,, 14,435 (1906). Bloxam (Neue Photographische Ges.) Photographic pigment paper. Nov. 7.

XXII.—EXPLOSIVES, MATCHES, &c.

[A.] 24,240. Claessen. Explosives.* Oct. 30.
,, 25,291. Haffner. Manufacture of matches. [Belg. Appl., Nov. 10, 1905.]* Nov. 9.
[C.S.] 25,081 (1905). Cooking, and Kynoch, Ltd. Solvents for nitrocellulose in the preparation of explosives. Nov. 7.
,, 6705 (1906). Venier. Explosives. Nov. 21.
,, 20,889 (1906). Luis and Williamson. Explosives. Nov. 14.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

[A.] 24,405. South Staffordshire Mond Gas Co., and Pinnock. Portable gas analysis apparatus. Nov. 1.

MR. ALEX. E. TUCKER IN THE CHAIR.

THE INFLUENCE OF SMALL QUANTITIES OF ELEMENTS IN COPPER UPON ITS REACTIONS WITH NITRIC ACID.

J. H. STANSBIE, B.SC., F.I.C.

The investigation now to be described is a continuation of that contained in a paper (this J., 1906, 45—50) in which attention was directed to the gases liberated by the action of nitric acid on copper containing varying small proportions of arsenic, antimony, and bismuth.

In this paper some of the changes brought about in the solution during the dissolution of the metals and alloys and the escape of the gaseous products are described.

The nitric acid.—The ordinary pure acid used in the laboratory, which was found to contain traces of sulphate and chloride, and to leave a small residue on evaporation, was slowly distilled from a Wurtz flask. The distillate was then heated on a water-bath to 60° C., and a current of pure dry air aspirated through it until it became perfectly colourless, the aspiration being continued during the cooling of the acid.

The sp. gr. of the acid thus prepared was found to be 1·437, and it was diluted to give a solution of sp. gr. 1·2 the water used being redistilled in the same way as the acid itself. The 1·2 acid was found by titration to contain 396·27 grms. of nitric acid per litre. The 1·2 acid was then tested for impurities. No indication of chlorine in 50 c.c. of the solution was given by silver nitrate, even after standing for several days. A very faint indication of sulphuric acid in the same volume after neutralisation with pure sodium carbonate was given by barium chloride. 50 c.c. of the acid was evaporated in a weighed platinum dish, which increased in weight 0·2 mgrm., and showed a small stain in the centre. A careful examination for nitrous acid made by Griess's test with standard solutions of metaphenylenediamine and sodium nitrite, showed 1·5 mgrm. of nitrous acid in 1000 c.c. of the acid.

The acid obtained as described above was used for the experiments, and sufficient was prepared at once to carry out the complete series. The apparatus, which is described in the paper referred to above, was modified by passing a siphon tube through the bung to the bottom of the beaker in which solution of the metal was effected; this was used to transfer the solution from the beaker to the flask without bringing it into contact with the air. Preliminary experiments showed that it was necessary to measure accurately the volume of the acid solution used, so that instead of simply bringing the end of the nozzle of the burette on to the top of the tube delivering the acid into the beaker, it was ground into the bore of the tube; it could be thus brought into exactly the same position, and the accurate delivery of the same volume of acid for each experiment was ensured.

The principal aim of the investigation was to determine the amount of nitrous acid formed in the solution during the dissolution of the metal or alloy. It was, therefore, necessary to keep the solution out of contact with the air until the free acids had been neutralised. After a number of trials, it was decided to neutralise the solution with excess of pure sodium carbonate, and to determine the amount of nitrous acid in it by titration with standard solutions of potassium permanganate and ferrous ammonium sulphate. The excess of sodium carbonate in the solution was determined by standard acid solution, with methyl orange as indicator. Copper is not always completely precipitated from its solution in nitric acid by excess of sodium carbonate at the atmospheric temperature until it has stood for 48 hours. Precipitation is completed on boiling, but it was thought that an operation would be avoided by allowing the precipitation to become complete in the cold, although boiling does not affect the sodium nitrite in alkaline solution. In fact the stability of the nitrite in the presence of excess of sodium carbonate was very marked. Boiling the solution, or allowing it to stand for several days, did not alter the amount of nitrite as determined by permanganate solution. Even air or oxygen may be aspirated through the solution without affecting the nitrite. So that when the nitrous acid is once neutralised, no difficulty is experienced in its accurate determination.

The experiments were conducted as follows: The metal or alloy is reduced to fine filings, sifted through brass gauze with 64 meshes to the linear inch, and magneted; 1 grm. of the filings is transferred to the dry beaker in which the dissolution is to be effected. The acid is run into the burette, levelled, and raised to 65° C. by hot water in the water jacket. The beaker is placed in position, connected with the gas cylinder, and the water lute run round. The water-bath is brought into position, and the acid allowed to run in drop by drop. When solution is complete, previously boiled water is run into the beaker from the burette to displace the gas, the gas cylinder is disconnected, and the delivery tube of a wash bottle containing boiled water connected with the gas-delivery tube leading to the beaker. The siphon tube is then opened, and a 500 c.c. flask about half full of a solution containing 6·0 grms. of pure sodium carbonate, brought into position with the siphon tube reaching nearly to the bottom. The solution in the beaker is then siphoned over by blowing into the wash-bottle to commence the action. When sufficient liquid has siphoned over the connection is broken, the parts of the apparatus which have been in contact with the solution well washed, and the washings added to the flask. The flask, after being well shaken, is made up nearly to the mark, well stirred, and set aside till the next day; it is then filled up to the mark, the contents well mixed, and allowed to stand another day for the complete precipitation of the basic copper carbonate.

The solution is filtered into a dry flask, the filter having been previously washed with a portion of the same solution, and 50 c.c. withdrawn by a pipette for determining the nitrous acid, and the excess of sodium carbonate. The permanganate solution is made so that 1 c.c. = 0·001 grm. of nitrous acid. It was standardised by ferrous ammonium sulphate, and checked by titrating a solution of pure silver nitrite with it. The ferrous ammonium sulphate solution used for the reduction of the excess of permanganate added to ensure the complete oxidation of the nitrite, was made so that 10 c.c. = 5 c.c. of the permanganate solution.

The determination of the nitrous acid is carried out as follows: 50 c.c. of the solution is run from a pipette into a conical flask, excess of permanganate is then added from a burette, and dilute sulphuric acid added. When the oxidation of the nitrous acid is complete, 10 c.c. of the ferrous solution is run in, and the excess oxidised by further addition of permanganate. After the necessary corrections have been made, the volume of the permanganate divided by 100 gives the weight of nitrous acid in mgrms. in 500 c.c. of the solution. Always two, and sometimes three titrations were made with each solution.

The excess of sodium carbonate is determined by titration with standard nitric acid solution, of which 1 c.c. =0·01 grm. of sodium carbonate. The volume of acid solution, divided by 10, gives the weight of free sodium carbonate in 500 c.c. of the solution.

The arrangemen of the results is based upon the following considerations:—

The weight of nitrous acid formed in an experiment

being known, the weight of sodium carbonate required to neutralise it can readily be calculated. The excess of sodium carbonate is known, so that the total weight used for neutralisation is obtained by difference. This consists of the part used to neutralise the excess of nitric acid, to precipitate the copper from the copper nitrate, and to neutralise the nitrous acid. By subtracting the weight of the latter, the weight of carbonate used up by the free nitric acid and the nitrate together is found. The copper nitrate is equivalent to free nitric acid, so that the weight of the free and combined nitric acid can be calculated. The weight of nitric acid used in the oxidation of nitric oxide to nitrous acid is given by :—

$$2NO + H_2O + HNO_3 = 3HNO_2$$
$$44{,}640 \text{ c.c.} \qquad 63 \text{ grms.} \quad 141 \text{ grms.}$$

And the volume of nitric oxide so oxidised can be calculated. Also, since the volume of nitric oxide liberated from the solution is known, the total volume of nitric oxide produced during the dissolution of the metal is also known, the solubility of the gas in water being neglected.

The weight of nitric acid used in an experiment was determined by running the required volume of the acid solution from the burette into a 500 c.c. flask containing 6 grms. of sodium carbonate in solution, making up to 500 c.c., and then titrating with the standard acid solution for excess of the sodium carbonate. This was checked by running through a blank experiment, in which all the conditions of an ordinary experiment were observed, except the addition of the metal.

Excess of sodium carbonate when the acid was run in = 1·014 grm.

Excess of sodium carbonate with the blank experiment = 1·018 grm.

Then $4{\cdot}984 \times \frac{126}{106} = 5{\cdot}926$ grms. of nitric acid.

Pure copper.—The following results, which are the mean of five experiments, were obtained with the pure metal :—

One grm. of copper, 5·926 grms. of nitric acid, and 6 grms. of sodium carbonate were used for each experiment.

Titration with permanganate.

Volume of permanganate required for 50 c.c. of solution	= 12·85 c.c.
Weight of nitrous acid in 500 c.c. of solution	= 0·1285 grm.
Weight of sodium carbonate to neutralise 0·1285 grm. of nitrous acid	= 0·1442 „
Weight of nitric acid to oxidise dissolved nitric oxide	= 0·0574 „

Titration with standard acid.

Volume of acid required for 50 c.c. of solution	= 15·10 c.c.
Weight of sodium carbonate in excess in 500 c.c. of solution	= 1·510 grm.
Weight of sodium carbonate used in neutralising nitrous acid	= 0·1442 „
	1·6542 grm.

Then $4{\cdot}3458 \times 126 \div 106 = 5{\cdot}166$ grms. of nitric acid as free and combined acid. The volume of nitric oxide which would be produced by the decomposition of the nitrous acid in the solution is given $0{\cdot}1285 \times 44640 \div 141 = 40{\cdot}7$ c.c. So that the total volume of nitric oxide produced by the secondary reaction is $176 + 40{\cdot}7 = 216{\cdot}7$ c.c., when 1 grm. of copper is dissolved.

According to the ordinary equation, 1 grm. of copper would liberate 236 c.c. of nitric oxide by the decomposition of 0·6667 grm. of nitric acid, and convert 2 grms. of acid into nitrate; and 216·7 c.c. of nitric oxide would result from the decomposition of 0·612 grm. of acid.

Therefore the results show that 90 mgrms. of the acid disappear, and as little or no gas other than nitric oxide collects in the cylinder, it is probable that the complete reactions are somewhat more complicated than those shown by the ordinary equations.

Variations in temperature.—A number of experiments were made to determine the effects of varying the temperature at which the reaction takes place. 1 grm. of copper and 5·926 grms. of nitric acid were used in each experiment, and the other conditions were kept as constant as possible, the temperature of the reaction being the only variable. The results are given in the following table, in which the weights are expressed in mgrms. The total volume of liberated and dissolved nitric oxide is also given.

Temperature °C.	Total weight of nitric acid used.	Weight of free and combined nitric acid as nitrate.	Weight of nitric acid decomposed in production of nitric oxide.	Weight of nitric acid used in oxidising nitric oxide.	Weight of nitric acid used in other reactions.	Weight of nitrous acid in solution.	Total volume of nitric oxide in c.c.
15	5,926	5,164	556	120	86	268	198
25	5,926	5,156	585	122	63	274	207
35	5,926	5,162	608	108	47	241	215
45	5,926	5,172	616	82	56	184	218
55	5,926	5,176	611	74	66	165	216
65	5,926	5,166	612	57	90	129	217
75	5,926	5,169	613	50	94	112	217
85	5,926	5,177	598	38	113	84	212

An examination of the table shows that variations in the temperature at which the reaction takes place have practically no effect upon the secondary change by which nitric oxide is produced, although the rate at which the changes take place increases with increase in temperature. It has already been noticed that the volume of gas other than nitric oxide liberated during the reaction is small, and decreases as the temperature of the reaction increases; and the table shows that the weight of acid used up in changes not indicated under the conditions of the experiment varies somewhat with the temperature, but is by no means negligible. It would seem from this that either a soluble gas is liberated, or that some of the acid is neutralised by ammonia formed during the reactions.

The alkaline solution was examined for ammonia by Nessler's test. The solution from the reaction at 25° C. gave 0·9 mgrm. of ammonia, and that from the reaction at 65° C. gave 0·6 mgrm. in 500 c.c. These quantities would neutralise 3·33 and 2·2 mgrms. of nitric acid respectively, but these are small compared with the quantities shown in the table, and when the nitric acid from which the ammonia is formed is added it would not increase the quantities to more than 5 and 3 mgrms. respectively. So that, though ammonia is undoubtedly formed during the reaction of the copper and acid, it is not in sufficient quantity to account for the disappearance of the quantities of acid indicated. A blank experiment without the metal was carried through, and the alkaline solutions examined for ammonia, which was indicated by the Nessler test; but the difference was sufficiently marked to show the influence of the dissolving metal. The distilled water used for the experiments was found to contain a trace of ammonia, but it was not thought necessary to use ammonia-free water for the whole series. What becomes of the "lost" acid is worthy of investigation, but it requires more extensive apparatus than has been used so far. The curve A (Fig. 1) shows the decrease in the amount of nitrous acid in the solution as the temperature increases, and the curve B shows the practically constant volume of nitric oxide formed during the reactions at varying temperatures. This bears out the suggestion made by Dr. Frankland that the difference in the volume of the collected gas at different temperatures might be accounted for by the nitric oxide being less soluble in the hot acid.

The instability of nitrous acid in the nitric acid solution containing copper nitrate was demonstrated by aspirating a current of pure air through such a solution containing 1 grm. of copper. The solution, instead of being neutralised directly with sodium carbonate, as in the other experiments, was collected in a flask, which was then connected with the apparatus used for purifying the nitric acid, and a moderate current of air aspirated through it while its temperature was kept at 65° C. by

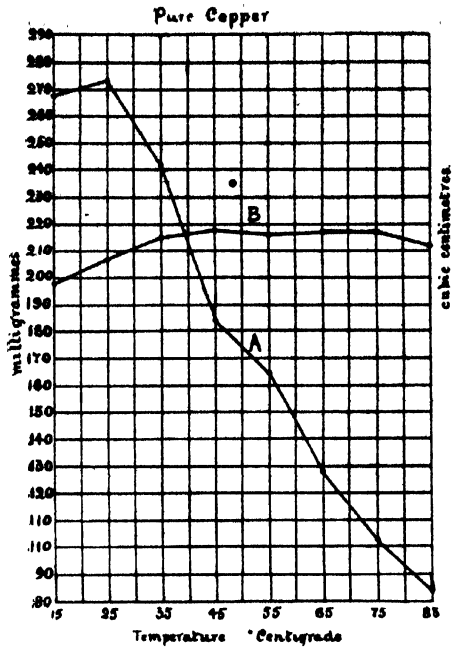

FIG. 1.

the aid of a water-bath. A long bulbed tube was interposed between the flask and the flexible tube leading to the pump. The further end of this tube showed no trace of condensation of liquid, and the tube itself was washed at the conclusion of the aspiration, the washings being added to the flask. In this way it was hoped to prevent any free acid from being carried off by the moist air leaving the flask. The solution was then added to a 500 c.c. flask containing 6 grms. of sodium carbonate in solution, and the experiment finished as described above.

The solution was found to contain 3·5 mgrms. of nitrous acid, as compared with 129 mgrms. found in the solution which had not been aspirated. This shows that the nitrous acid is either oxidised by the oxygen of the air passing through the solution, or that it is decomposed, and nitric oxide escapes with the issuing air. If oxidation takes place, the quantity of free nitric acid should increase in proportion to the weight of nitrous acid oxidised; but if nitric oxide escapes, the increase in the quantity of free acid would only be one-third of that weight.

The free nitric acid and nitrate in the solution required 4·455 grms. of sodium carbonate for neutralisation, which is equal to 5·297 grms. of nitric acid. Now from the table given above it is seen that, in the normal experiment, 5·166 grms. of nitric acid is indicated, so that there is an increase of 0·131 grm. in the free acid when the solution is treated with air at 65° C. If the whole of the nitrous acid which is shown to have disappeared during the aspiration were converted into nitric acid the increase would be 0·167 grm., but if it had been decomposed into nitric oxide and free nitric acid the increase would have been 0·056 grm. Therefore, the evidence is strongly in favour of the statement that the current of air passing through the solution oxidises the nitrous acid, and that only a comparatively small proportion is decomposed with evolution of nitric oxide in a moderately dilute solution. If, however, the solution is concentrated, and exposed to the air, nitric oxide escapes even after the whole of the metal has disappeared.

Bismuth and Arsenic.—As these metals, together with antimony, were dealt with alone as well as in the alloyed state in the previous paper, the experiments were continued with the bismuth and arsenic, but not with the antimony, on account of the practical impossibility of completely oxidising it in the 1·2 acid at 65° C.

Bismuth.—The results obtained with the bismuth are very interesting, as they show that the reactions taking place when the metal dissolves in the 1·2 acid at 65° C. are expressed by the equation:—

$$2Bi + 8HNO_3 = 2Bi(NO_3)_3 + 4H_2O + 2NO$$
415 grms. 44640 c.c.

This is proved by following statement of results:—1 grm. of the metal dissolved in 15 c.c. of the acid solution containing 5·926 grms. of nitric acid gave 0·0856 grms. of nitrous acid = 27·1 c.c. of absorbed nitric oxide and 79·5 c.c. of the evolved gas = 106·6 c.c. = total volume of nitric oxide liberated by the reaction of the acid with the metal; the volume calculated from the equation = 107·5 c.c.

The weight of free and combined nitric acid left in the solution = 5·598 grms. The weight of acid used for oxidation of nitric oxide in the solution = 0·038 grm. The weight of acid which disappears in the production of the nitrous oxide = 0·294 grm., as compared with 0·301 grm. as calculated from the equation. The total weight of acid thus accounted for = 5·930 grms. It is clear, therefore, that bismuth has little or no tendency to set up reactions other than the simple ones by which the production of nitric oxide can be explained.

Arsenic.—The experiments with arsenic furnished another interesting investigation. In the original experiments as described in the first paper, the so-called pure acid for use in the laboratory, which was found to contain traces of sulphate, chloride, and solid matter, diluted to 1·2 sp. gr., was used, and the arsenic dissolved rapidly in it at 65° C. But when the pure acid, prepared as already described, was substituted, the metal dissolved with difficulty, and much more slowly, although the result was the same. It evidently furnished an example of the influence of traces of impurity in the acid solution. Traces of sodium sulphate, sulphuric acid, sodium chloride, and hydrochloric acid were introduced separately into the pure acid, and it was found that the hydrochloric acid was the only one that accelerated the reaction between the arsenic and the acid. Since sodium chloride itself produces no effect, it would appear that the acceleration is due to the presence of a trace of free chlorine, which probably exerts a catalytic action, and thus promotes the general reaction between the arsenic and the nitric acid. The difference is very marked, for with the impure acid 0·5 grm. of arsenic dissolved completely in 15 c.c. of the impure acid at 65° C. in five minutes, whereas the same weight of metal under the same conditions required 55 minutes for complete solution when the pure acid was used. It was thought that the presence of nitrous acid in the acid solution might, as suggested by Dr. Price in his remarks on the first paper, exert some influence, and on that account the pure and impure acid were examined for the presence of the lower acid. The results were 2·1 mgrms. of nitrous acid per litre for the pure acid, and 3·2 mgrms. per litre for the impure acid. The difference is not sufficiently marked to account for the increase in the rate of action; and, further, it may be remarked that nitrous acid is formed in the solution as soon as the action commences, so that the presence of more or less nitrous acid in the original solution would not account for the difference in the rate of action. The presence of a trace of free chlorine gives the best explanation of the facts. It may be remarked that the arsenic furnished the only experiment in which any difference in the use of the ordinary pure acid and the specially purified acid was noticed. Even in the case of the arsenic itself small differences in the quantitative results could be accounted for by the difference in the rate of action. The following results for nitrous acid formed in the solution were obtained by the dissolution of 0·5 grm. of arsenic in 15 c.c. of the acid solution at 65° C. The solutions were neutralised with the sodium carbonate, and titrated with the standard permanganate in the usual way:—

(1) Ordinary acid gave 226 mgrms. nitrous acid.
(2) Purified acid gave 231 mgrms. nitrous acid.

(3) Purified acid with trace of chlorine gave 227 mgrms. nitrous acid.

For (1) the absorbed and the evolved nitric oxide = 238 c.c., and if it is assumed that the whole of the arsenic is oxidised to the pentoxide with liberation of nitric oxide and the formation of water the calculated volume is nitric oxide = 248 c.c., which is a close approximation to the observed result. Also it was found that 4·549 grms. of sodium carbonate was required to neutralise the free acid and the arsenic anhydride. Now if 0·5 grm. of arsenic is converted into 0·767 grm. of pentoxide it requires 0·7 grm. of nitric acid, so that there would be 5·784 – 0·7 = 5·084 grms. of free acid; but 0·1076 grm. of nitric acid is required for the oxidation of the absorbed nitric oxide, and the actual weight of free acid would be 5·084 – 0·1076 = 4·9764 grms.

This weight of acid would require 4·187 grms. of sodium carbonate to neutralise it, so that leaves 4·549 – 4·187 = 0·362 grm. for the neutralisation of the arsenic acid. By calculation 0·767 grm. of arsenic pentoxide is neutralised by 0·354 of the carbonate with formation of sodium dihydrogen arseniate (NaH_2AsO_4).

The facts stated above may be put into the form of an equation, thus:—

$$6As + 10HNO_3 = 3As_2O_5 + 5H_2O + 10NO$$

and show that the reactions between arsenic and nitric acid under the conditions stated are simple in character.

It should be noted that the weight of nitric acid in 15 c.c. of the ordinary acid is smaller than in the same volume of the purified acid, which is no doubt due to different methods being used for the determination of the specific gravity. The hydrometer method was used for the ordinary, and the weighing method for the purified acid.

Alloys of copper and arsenic.—The alloys used for the experiments, the details of which are given below, are the same as those used for the experiments described in the first paper. The experiments were carried through as already described for the pure metals, so that 1 grm of the finely-divided alloy, 5·926 grms. of acid in 15 c.c. of the solution, and 6 grms. of sodium carbonate were used for each experiment. The general results are arranged in the form of tables for easy reference, and the important quantities are traced on curves to render the relations more obvious. All weights are expressed in milligrams and to the nearest milligram, as this enables whole numbers to be used, and thus brings out the general relations more readily.

Alloys of copper and arsenic.

Arsenic per cent.	Total weight of nitric acid used.	Total weight of nitric acid free and combined as nitrate and oxide.	Weight of nitric acid decomposed in production of nitric oxide.	Weight of nitric acid used in oxidising dissolved nitric oxide.	Weight of nitric acid used in other reactions.	Weight of nitrous acid in solution.	Total volume of nitric oxide in c.c.
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
0·00	5,926	5,166	612	57	90	129	217
0·05	5,926	5,297	468	45	121	100	164
0·10	5,926	5,369	427	37	153	82	152
0·25	5,926	5,260	432	44	190	96	153
0·50	5,926	5,278	449	46	153	102	159
0·75	5,926	5,299	477	48	102	107	169
1·00	5,926	5,288	505	49	83	111	179
1·50	5,926	5,259	539	54	74	120	190
2·00	5,926	5,248	563	52	63	122	196
2·50	5,926	5,208	570	53	94	119	202
3·00	5,926	5,190	601	57	78	129	213

Note.—All weights are given in mgrms.

It will be noticed that the decrease and increase in the nitrous acid in solution follows the same general law as the decrease and increase of the liberated nitric oxide as the percentage of arsenic increases. See columns (1) and (7) in the table, and curve B, Fig. 2. Column (8), and curve A, Fig. 2, also show that the total volume of liberated and dissolved nitric oxide decreases and increases in the same general way, giving a minimum volume below

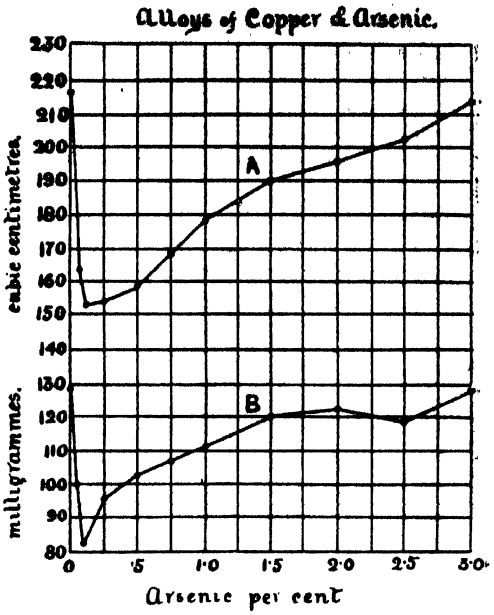

FIG. 2.

0·25 per cent. of arsenic. The weight of the "lost" acid also increases and decreases, but in this case the increase is accounted for in the liberation of the other gas, most probably nitrogen from its insolubility, which follows the same law.

Alloys of copper and antimony.—The remarks made in connection with the alloys of copper and arsenic also apply generally to the copper-antimony series, but the influence of the antimony is less marked than that of arsenic. This is seen by reference to columns (1), (7), and (8) of the table given below, and is emphasised by the curves A and B in Fig. 3.

Alloys of copper and antimony.

Antimony per cent.	Total weight of nitric acid used.	Weight of nitric acid free and combined as nitrate and oxide.	Weight of nitric acid decomposed in production of nitric oxide.	Weight of nitric acid used in oxidising dissolved nitric oxide.	Weight of nitric acid used in other reactions.	Weight of nitrous acid in solution.	Total volume of nitric oxide in c.c.
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
0·00	5,926	5,166	612	57	90	129	217
0·05	5,926	5,182	593	58	95	130	210
0·10	5,926	5,218	580	57	71	129	205
0·25	5,926	5,217	561	54	94	120	197
0·50	5,926	5,193	552	56	105	126	194
0·75	5,926	5,210	559	57	100	127	197
1·00	5,926	5,202	564	59	101	132	200
1·50	5,926	5,217	568	60	81	134	202
2·00	5,926	5,181	586	61	98	136	208
2·50	5,926	5,181	584	59	102	134	207
3·00	5,926	5,168	589	60	110	135	208

Note.—All weights are given in mgrms.

Alloys of copper and bismuth.—In this series of alloys the characteristic action of antimony and arsenic disappears entirely. In fact, the numbers obtained seem to point rather to a reverse action in the case of the alloys up to about 0·25 per cent. of bismuth. It has been noticed already that pure bismuth seems to give a comparatively simple set of reactions with nitric acid, and this is borne out by the alloys up to 0·25 per cent.

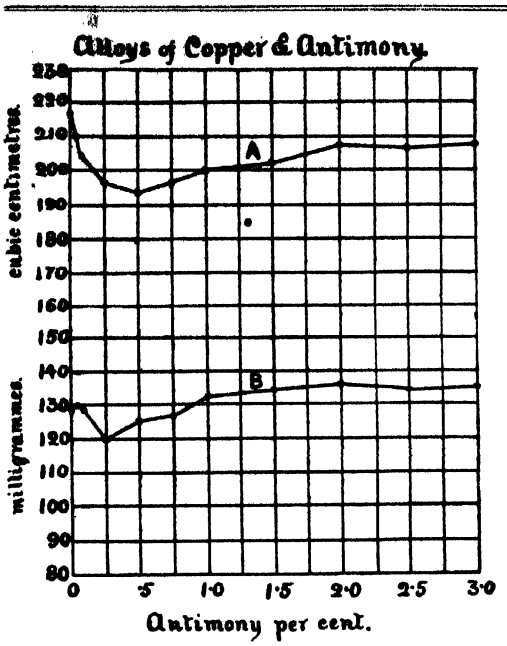

FIG. 3.

The general relations are given in the table, and shown in the curves A and B, Fig. 4.

Alloys of copper and bismuth.

Bismuth per cent.	Total weight of acid used.	Weight of free and combined nitric acid as nitrate.	Weight of nitric acid decomposed in production of nitric oxide.	Weight of nitric acid used in oxidising dissolved nitric oxide.	Weight of nitric acid used in other reactions.	Weight of nitrous acid in solution.	Total volume of nitric oxide in c.c.

Note.—All weights are given in mgrms.

Several conclusions can be drawn from the results given in this and in the first paper. The chief experiments are those which prove that the introduction of small quantities of foreign elements into pure copper has a marked influence on the character of the reactions between the metal and nitric acid. This is so decided in the case of arsenic and antimony as to leave no room for doubt as to its existence. Why this is so, still requires explanation, and nothing further can be added to the suggestion, already put forward, that the percentage of impurity which gives the most marked effect is that which, when in combination with copper, forms the most perfect solid solution of the compound in the excess of copper. Some colour is given to this by the fact that bismuth, which does not appear to form any compound with copper stable at ordinary temperatures, seems to exert an

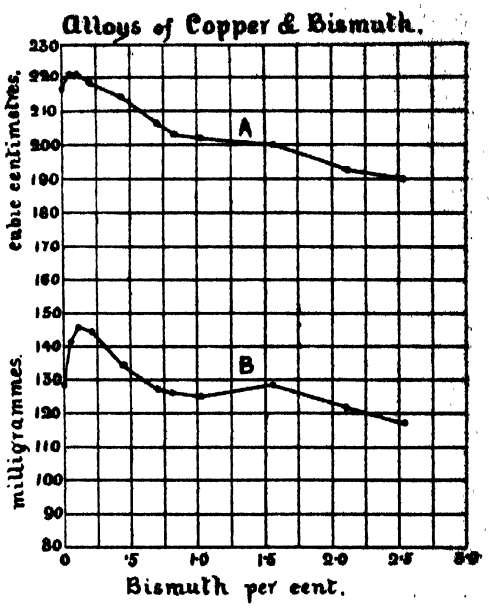

FIG. 4.

influence proportional to the quantity present in the alloy, for there is no marked minimum such as occurs with the arsenic and antimony alloys. There is no doubt that the presence of small portions of these elements in the alloys have a maximum disturbing effect upon the energy relations of their masses with the acid solution into which they dissolve. Whether this is due entirely to purely chemical relations is an open question, but it is worthy of note that as the atomic volume of the impurity increases its effect decreases.

The two variables which exert the greatest influence on the rate of action, and in the distribution of the products of the action, are concentration of acid, and temperature. This is brought out clearly in dealing with pure copper. There is no doubt that the main reactions by which nitric oxide is formed are influenced very little by variations in the temperature at which they take place, but the distribution of the gas between the solution and the atmosphere above it is clearly a function of the temperature. This is very marked over a wide range of temperature, and there is no difficulty even in detecting the effect of a variation of 2° or 3° in two experiments.

The formation of ammonia is also apparently a function of the temperature, but it may be that the effect of an increase in temperature is to cause the decomposition of ammonium nitrate with liberation of nitrous oxide almost as fast as it is formed. This would account for the smaller quantity of ammonia at the higher temperature.

The "lost" acid presents a problem which must be solved before the reactions can be fully explained, but it may be noticed that the formation of ammonium nitrate and its decomposition into nitrous oxide would account for some of it, as the solubility of the nitrous oxide would cause its disappearance from the main bulk of gas remaining for measurement. The simple character of the reactions for bismuth and arsenic, which leave very little "lost" acid to be accounted for, should be noted.

DISCUSSION.

Dr. T. S. PRICE asked whether the speaker considered that nitrous acid was produced by a secondary reaction, viz., the oxidation of nitric oxide by nitric acid, or did he assume that it might also be produced primarily by a

reduction of nitric acid during the reaction? What evidence was there in support of the supposition that all the nitrous acid was produced by oxidation of the nitric oxide? With respect to the effect of hydrochloric acid on the reaction between nitric acid and arsenic, it seemed to him curious that certain chlorides did not act in a similar way, since on adding a chloride to the nitric acid, hydrochloric acid was certain to be produced.

Mr. H. L. HEATHCOTE said the fact that arsenic dissolved so slowly in pure nitric acid called to mind the behaviour of iron in nitric acid that was pure. Iron was passive towards most grades of nitric acid, particularly when pure. It was quite possible that they had to do with the passive state, or the partially passive state, of arsenic. Bismuth, as discovered by Andrews, showed a passive condition in nitric acid. Copper also exhibited this condition. Arsenic, so far as he was aware, had not been observed in a passive condition. This might be the first observation of that. If that were the case, then the electrolytic processes which went on when the metal was dissolving might have something to do with the "lost" acid. He suggested that the becoming passive of a metal was caused by the little local currents which were produced at the surface; since such local currents were produced in the case of copper, they might give an explanation of the "lost" acid. That hypothesis, he thought, was borne out by the becoming passive of the arsenic, in which condition there would be no local currents.

Mr. LEWIS asked what would be the effect if preparations of powdered bismuth, arsenic, and antimony were mixed with powdered copper in the same proportion as the alloyed metals. Did lead also produce the same effect as bismuth?

Mr. J. E. STACEY JONES said he found it exceedingly difficult to get nitric acid absolutely free from sulphur for the determination of sulphur in rubber as well as in steel. He was recently in want of some acid in a hurry, and could not wait to get it in the ordinary way of commerce; he, therefore, had to attempt to make it. He tried to distil it as the author described, and found there was practically as much sulphuric acid in the distillate as previously. Afterwards he distilled it over barium nitrate, and removed 80 to 90 per cent. of the sulphate But there was some sulphate there even after taking all precautions. He also asked whether the author could enlighten him on a good process of purification of fuming acid.

Mr. STANSBIE, in reply, with regard to Dr. Price's question about the reduction of nitric acid to nitrous acid direct, said that was a matter which he had not considered at present. In the experiments he had been carrying out, it had proved rather difficult to get results on account of the many variations which might take place. He was modifying the apparatus which he had used so far, and he hoped to have more to say about the question, later on, as to whether the nitric oxide was simply liberated, and then oxidised to nitrous acid by nitric acid—that was a perfectly possible reaction—or whether nitrous acid was simply the result of partial reduction, or more than partial reduction, of the nitric acid. With regard to the action of hydrochloric acid and common salt when added to pure nitric acid, he could only say that he got a result with the acid that he did not get with the salt. He was now investigating whether nitric peroxide was one of the products of the decomposition of nitric acid by pure copper. He thought later he would be able to prove that it was. The subject required a lot of work to obtain anything like accurate information about it. As to what Mr. Heathcote said of bismuth, he agreed that a passive condition was usually induced when the acid was strong. The stronger the acid, the greater tendency for the passive condition to be induced in the case of a metal, whether iron or bismuth or what not. But in all his experiments with bismuth, the metal dissolved rapidly in the 1·2 acid. As stated in the paper, the arsenic was the only metal he had dealt with in which he had noticed any difference whatever in the action when the impure acid was used, and when the purified acid was used. He was still making investigations as to "lost" acid. It was completely lost to sodium carbonate, and therefore he had called it by the name "lost" acid. The only objection he had to the use of oxalic acid for titrations was that it was rather slower than ferrous ammonium sulphate. The sulphate worked consistently, and was stable in dilute solutions. He would try oxalic acid again, and if it were safer he would be glad to use it. In reply to Mr. Alcock, he could not say whether the coloration produced in nitric acid after dilution was due to the presence of iron in the acid; that was a matter for investigation. Experiments with simple mixtures of copper, bismuth, antimony, and arsenic were fully described in the first paper. For every alloy used the corresponding mixture was prepared—the effect of the added element was found to be simply that of an added constituent of the mixture; he meant by that that one could calculate from the composition of the mixture the volume of nitric oxide which had been liberated, showing that the simple act of mixture had no effect upon the reaction between the metals and the acid. He had not done any experiments with lead in copper at present. A considerable percentage of lead (as compared with bismuth) might be added to copper without its liquating. Bismuth sweated out in small globules over the surface of the alloy. Those globules, on analysis, were found to be pure bismuth. The only copper he got in the solution was that probably scraped off in removing the globules. He had taken much trouble on the subject of the purification of nitric acid, and found that any sulphate present was concentrated in the residue from the distillation. With the first experiments his object was to show that with alloys of arsenic and copper and so on there would be a differential action. He took the nitric oxide as a sort of indicator, without any thought particularly of the acid. The same acid was used in the whole series of experiments, and the differential action obtained was due to impurity in the metal.

Meeting held at Sydney on Tuesday, August 21, 1906.

DR. R. GREIG-SMITH IN THE CHAIR.

A POSSIBLE NEW COMMERCIAL SOURCE OF ALCOHOL.

BY E. A. MANN.

Investigations have been proceeding for some months in the Government Laboratory, Perth, W.A., on the *Xanthorrhœa preissii*, a plant confined to Western Australia, and which, in common with other species of the same genus occurring throughout Australia, is known as the "grass tree."

From its peculiar character and appearance, which forms a striking feature of our bush scenery, this plant naturally excites curiosity and interest; apparently useless, it nevertheless occupies large tracts of country, in the clearing of which it has, in the past, been ruthlessly destroyed, and it is hardly surprising, therefore, that attempts have been made from time to time to ascertain whether it could not be turned to some practical use. It is said to have been used as a source of picric acid; and being of a very resinous nature, its exudations have been tried in the manufacture of varnish, samples of the resin having been sent to England to ascertain their value in this respect, but it is reported to lack "body," and to be of no value, except for the cheaper and inferior classes

of varnish. On the other hand, it is said to have been successfully used in Queensland.

A more interesting attempt to turn it to practical account is that which has been made locally, by Mr. Charles Harper, of Guildford, in this State, and which led largely to my own investigation. Mr. Harper, in endeavouring to produce from the grass tree a fodder for cattle, prepared from the interior core of the stem of the plant a meal, which, I believe, has been used on stock with encouraging results. On submitting a sample of this fodder to analysis, the following results were obtained:—

Moisture, 9·19 per cent.; fat, 0·78 per cent.; albuminoids (N × 6·33) 2·83 per cent.; fibre, 35·93 per cent.; ash, 0·40 per cent.; carbohydrates (by difference), 50·87 per cent.

The carbohydrates were found to consist of:—

Reducing sugars (calculated as dextrose), 10·25 per cent.; non-reducing sugars (calculated as cane sugar), 15·86 per cent.; and other carbohydrates (by difference), 24·76 per cent.

Attempts were made to isolate the sugars in a pure form by crystallisation, but this was found to be impossible, owing to the large amount of interfering substances present; it occurred to me, however, that if they could be fermented, they might possibly be made a commercial source of alcohol. 350 grms. of the meal were extracted with boiling water, and the solution thus obtained was fermented with yeast. Fermentation proceeded vigorously. It was found that the sugars had been practically all fermented, as judged by the action on Pavy's solution, and the resulting alcohol was separated by distillation, yielding 300 c.c. of an alcoholic solution containing 8·34 per cent. of absolute alcohol by weight, or equivalent to 18·3 per cent. of sugar in the original meal. This return was equivalent to 1·24 galls. proof spirit per bushel (60 lb.) of the meal, whereas by the copper reduction method 25 per cent. of sugar had been found; the difference between the original amount of sugar present and that represented by the alcohol formed might be due either to variation in composition of successive samples of meal, or to the presence of other substances which reduced the copper solution.

Further, theoretically, pure sugar should yield 51 per cent. of alcohol, but only about 1 proof gallon is usually obtained from 10 lb. of sugar. Recalculated on this basis, the sugars amounted to 20·6 per cent.

A second extraction with 6 lb. of core, and a third with 2½ cwt., gave smaller proportionate yields, possibly due to variations of moisture in the meal, and to the specimens being gathered at different seasons of the year.

The various results obtained were:—

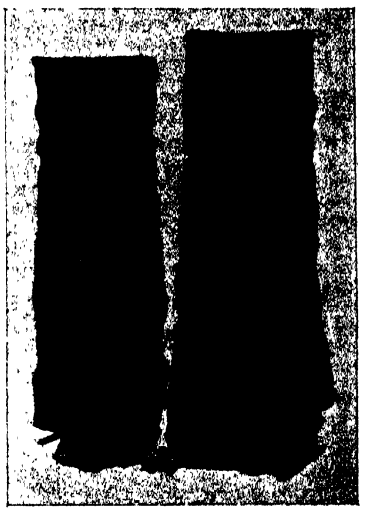
Month.	Weight of sliced core.	Proof galls. spirit per bushel (60 lbs.).	Equivalent sugar per 100 core.	Per cent. sugar by analysis.
September	350 grms.	1·24	20·6	26·1
February	6 lb.	0·8	13·3	not determined.
June	2½ cwt.	0·5	10·0	10·5

The yield of alcohol from various materials may be stated as follows:—

	Yield in proof galls. per bushel. (60 lb.).
Pure starch	4·68
Wheat, rye, barley, oats, buckwheat, maize, average	2·08
Malt	2·00
Potatoes (containing 21 per cent. starch)	1·26
Sugar cane (containing 12 per cent. sugar)	0·72
Beet (containing 10 per cent. sugar)	0·60
Grass-tree core	0·5 to 1·24

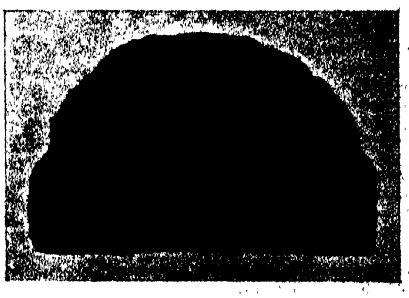
There are certain side issues which might be worth pursuing at the same time, if the manufacture of spirit from the grass tree were taken up on a large scale, viz.:—

1. The resin present in the outer shell or covering of the trunk could probably be utilised for making cheap varnishes as already indicated, grass-tree spirit itself being used as a solvent.



2. The outer strippings of the trunks could be used as an excellent fuel for raising heat in connection with the extraction and distillation.

3. The whole core contains a large percentage of fibre, which is short, and already in a suitable condition for use, and it has been suggested that this could be used to advantage in the manufacture of strawboard and rough paper.



4. The green leaves of the plant have a certain value as fodder for stock.

The plants are readily knocked over, and the outer scaly protective covering or shell is easily removed.

In the accompanying photographs are shown longitudinal and transverse sections of the trunk of the grass tree, in which the very curious and interesting arrangement of the fibres in the core can be distinguished. From

LONGITUDINAL SECTION OF TRUNK, showing outer shell and core. The latter exhibits a layer of longitudinal fibres next to the outer shell. Average diameter of core, 6½ ins.

TRANSVERSE SECTION OF TRUNK showing radial character of core, and outer layer of longitudinal fibres next to the shell.

the centre, fibres radiate to the circumference, and are interlaced by longitudinal fibres passing down through it

core; the latter are specially accumulated in an outer layer next the surrounding outer shell composed of dead leaf bases. Between these interlacing fibres is contained the "meal" which contains the sugar.

I have to acknowledge valuable assistance given by Dr. W. H. Ince and Mr. T. J. Wallas, in connection with the laboratory work arising out of this inquiry.

Discussion.

Mr. T. U. Walton said that as nothing had been done in the way of identifying the sugars, one could only speculate as to their nature; but the fact of the non-reducing sugar being completely inverted by boiling for a short time was sufficient to show that it was not cane sugar. Possibly a glucoside was present, which yielded the additional proportion of glucose on boiling.

Mr. T. Steel said that the resin of the grass tree was an article of commerce, being collected and shipped to Europe and America. He agreed that cane sugar would not be inverted as described, but doubted if a glucoside could be present in quantity sufficient to yield 15 per cent. of glucose. He suggested that there might be a readily hydrolysable gum. As long ago as 1866 (Trans. Roy. Soc. Victoria), Ligar suggested the Xanthorrhoea as a source of alcohol, and in 1876 a patent was applied for in Melbourne for the manufacture of sugar from it. As a source of alcohol he did not think the plants could be profitably used, for they would soon be cut out and were slow growers. Besides, in Australia there was molasses as a waste product containing 50 per cent. sugar.

Mr. W. A. Dixon said that the resin from the grass tree was unsuitable for varnish making, because it contained the soluble benzoic and cinnamic acids, which made the varnish show stains with water.

Yorkshire Section.

Meeting held at the Queen's Hotel, Leeds, on Monday, October 29, 1906.

Mr. F. W. Branson in the Chair.

CHAIRMAN'S ADDRESS.

The Canal System and the Means of Internal Transport.

By F. W. Branson.

Abstract.

I propose this evening to briefly introduce for the consideration of the members of the Yorkshire Section of the Society of Chemical Industry, an important national question, *viz.*, the improvement of the canals and inland navigations of the United Kingdom.

One of my predecessors, Mr. James E. Bedford, suggested, in 1903, important extensions of the waterways of Yorkshire, and urged that the entire canal systems of the country should be improved. Since that time progress has been made, and a Royal Commission has been appointed. Careful consideration has been given to the project by the Council of this Society, an Internal Transport Committee having been appointed to co-operate with any similarly-constituted authorities with a view to secure much-needed reform. Various Chambers of Commerce, &c., have also given much attention to the entire question. Fortunately the problem to be solved is not a political one, but it is difficult and complicated owing to the extent and variety of the vested interests concerned (*e.g.*, two-seventhe of the existing canals are controlled by various railway companies). Other difficulties are the variation in size of the existing canals, which prevent satisfactory through routes being arranged, the deficiency of water supplies, and many other causes. The proper development of the canal systems of this country will not, I feel sure, affect adversely the interests of the railway companies as a whole, but benefit them. Mr. Rowland H. Barran, M.P., has again introduced a "Canals Bill," which is supported by several leading manufacturers and members of the Society of Chemical Industry. The careful attention of all traders should be given to the consideration of so important a measure. The Bill contains the following memorandum: "This Bill proposes to constitute a strong Central Canals Board for the purposes of obtaining Provisional Orders authorising the Board to take over, improve, and manage, in the first instance, certain canals which form a chain of navigation between the principal ports of England. Powers are also taken for subsequently acquiring by Provisional Orders other canals (with the exception of the Manchester Ship Canal), and for their improvement and management. The object of the Bill is by such a consolidation of interests and management to improve the facilities for water-carriage, and to establish a complete system of intercommunication." The Bill also provides: "That no chairman, director, manager, or other official of a railway company shall be eligible for the office of a member of the Board." It is proposed that the Canals Board shall consist of 23 members, of whom 15 shall be appointed and 8 elected. A carefully considered scheme has been put forward by Mr. J. A. Saner, whose proposition is that a system of intercommunicating canals shall be constructed for vessels of 300 tons to connect, in one system, the ports of London, Liverpool, Hull, and Bristol with Birmingham in the Midlands, and that two transverse systems in connection with the foregoing shall be constructed to connect Liverpool to Hull, and London to Bristol respectively. It is obvious that without legislation little can be achieved, and this will be difficult unless public opinion vigorously supports the action taken by the Mansion House Association on Railway and Canal Traffic, and other allied organisations. As to the cost of such a gigantic scheme, Mr. Saner has estimated that the Hull to Liverpool Section would cost £1,300,000; Hull to Birmingham, £2,700,000; Birmingham to London, £2,300,000; Birmingham to Bristol, £1,600,000; Birmingham to Liverpool, £2,200,000. To purchase existing canals on the basis of 20 years' purchase, assuming an annual net profit of £500,000, and allowing £1,000,000 for contingencies, would mean, in addition to the above sums, about £11,000,000, making a total of about £21,000,000. Assessing the present annual income of canals at £1,500,000, the traffic would, in his opinion, require to be practically doubled in order to make the scheme a financial success. On such a system as Mr. Saner is anxious to see carried out it is calculated that it will be possible for the mileage ton rate to cost for fuel, labour, and depreciation as little as ½d. per ton per mile for barges of 100 tons, and the rate would be considerably less for cargoes carried in steamers of, say, 300 tons. It is perfectly obvious, therefore, that there is great scope, especially in Lancashire and Yorkshire, for water carriage for certain classes of traffic, such as heavy and risky chemicals, coals, minerals, breakable goods, &c., &c.

The address was illustrated by lantern slides showing the present canal system, and differentiating the canals owned by the railway companies; also a map showing the new system as proposed by Mr. Saner.

Discussion.

Mr. Wardle (Vice-President, Leeds Chamber of Commerce) said that the cheapest water communication was carried on by private boats, and half the tonnage between Hull and Leeds was of this description. The Leeds Co-operative Society had a large number of private boats. He thought he was correct in saying that the rate from Hull to Leeds was a good deal more than 1d. per ton per mile, whilst according to Mr. Saner's estimate the cost would only be ½d. per ton per mile if the suggested

extensions of the canal system were carried out. As an example of an industry which had suffered on account of high rates of carriage, he mentioned that oil-crushing, which had been in this country first started in Leeds, had now been taken to Hull. It was, therefore, very important that Leeds and the West Riding should have cheaper communication with the sea. The most ardent advocates of improvement were the people of Birmingham and Bristol, where the canal trade suffered on account of the small guage of some of the connecting canals and the want of a uniform depth and width for boats of a fairly large size. The former city would benefit enormously by the introduction of such an improvement. The opposition of the railway companies was the most formidable obstacle, and their power was great, especially in Parliament. The improvement of waterways would, however, be an advantage even to them by the resultant expansion of the trade of the country. On the Continent the action of the French and German Governments had brought down the inland freight in some cases below 25 per cent. of that in this country. The success of German industries as shown by such works as those of the Badische Analin und Soda Fabrik on the Rhine was in no small degree due to cheap freights and adequate internal water communication.

Mr. W. P. BOWMAN thought it was necessary in the interests of the trading community to reduce the rates. The system of classification adopted by the railway companies made it more and more difficult in sending parcels of mixed goods. They would not now allow mixed consignments, but insisted on separate parcels for each different class of goods. Their inspectors were authorised to unpack goods in the yards or stop them in transit for the purposes of examination, often at the risk of damage or delay. It was, therefore, advisable to further the extension of waterways, especially since railways and most of the present canal companies acted together to such an extent that there was only a slight difference in rates, and practically no competition between them.

Mr. W. McD. MACKEY drew attention to the fact that under the railway bills as originally drawn the public had a right to use the railroads in common with the railway companies, and in law the right still existed. That is, one might run a private carriage or wagon on the railroad. Unfortunately, though, for the public the railway company was under no obligation to work the points for it. In the case of coal, water carriage had the great advantage over the railway, in freedom from breakage. Breakage occurred mainly in the shunting, and was a serious and recognised source of loss in the coal trade. This subject, though not strictly chemical, fell well within the scope of the Society; and he thought that some of the time that was annually spent in discussing Continental methods of technical education might with advantage be devoted to other subjects such as this, in which we really had much to learn from the Continent, where, especially in France, water carriage was being rapidly developed, whereas with us it was actually declining. He was struck when in Staffordshire with the usefulness of the canal system there. It seemed to fulfil for certain districts, as far as the carriage of heavy material was concerned, all the duties of a railway.

Mr. FAIRLEY gave an instance of the effect of heavy local carrying rates on industries. He mentioned a case in which it was cheaper to send goods by rail from Manchester to London and thence to Macclesfield, than direct. This showed the advantage cheap water accommodation would give.

Prof. GARDNER asked if figures were available to prove that water carriage under average conditions was actually cheaper than that by land.

Mr. R. K. CALVERT thought that railways could not altogether be blamed for taking up canals, since in many cases in the early days of railways they had been forced to this. One reason why canals had not developed in this country as on the Continent was that there were too many companies for such a small mileage. If the canals had been in fewer hands they might have agreed to adopt a uniform gauge. The question would have to be solved either by nationalisation of the canals or by a trust. Difficulties in the way of this were that prosperous companies might object to absorption of non-prosperous concerns, and that County Councils and other public bodies not gaining direct benefit by the system might decline to contribute. The easiest and most feasible plan of action appeared to be for the Government to take up the matter rather than for it to be left to private enterprise. It was impossible to estimate the cost, but it would no doubt be a good thing if the State were able, as had been suggested, to buy up the waterways on the basis of a twenty years' purchase of the nett profits of the canal system. It was advantageous to have canals made like the Bridgewater Canal, without locks. Leeds owed much of its prosperity to the waterways of the Aire and Calder Navigation, and the Leeds and Liverpool Canal.

Mr. F. W. BRANSON, in reply, said that canals should be used for what suited them. Some classes of material could not be conveyed by rail. Figures showed that there was no comparison between the rates by rail and water. Although Leeds was indebted to the Aire and Calder, it was advisable that the rates should be still further reduced. Many interests, such as agriculture, would benefit enormously by development of water communication.

The Chairman exhibited the following:—A new device enabling the operator in micro-photography to see and adjust the polished and etched metallic surface immediately before taking the photograph. Also apparatus for preparing metals for photo-micrography; apparatus for photographing metallic surfaces with high powers; various kinds of pyrometers, &c.; sections of the Madder plant used by Sir W. H. Perkin, F.R.S., in his early researches on alizarine.

Prof. W. M. Gardner showed a sample of mauve dye made by Sir William Perkin at the time of his first discovery, and samples of silk dyed with the same.

LIVERPOOL UNIVERSITY. MUSPRATT LABORATORY.

A NEW building, which is to be ready for occupation before the end of the year, has been presented to the University of Liverpool by Mr. E. K. Muspratt. Under the title of "The Muspratt Laboratory," it is to be used wholly in the study of physical chemistry, and especially electro-chemistry, and will afford accommodation for at least 40 workers. It is one of the best equipped laboratories for that purpose, and, together with its electrical machinery, apparatus, and furnaces, will have cost its donor little less than £16,000. The building is one of four storeys, with its exterior faced with pressed red brick and stone, in harmony with the surrounding buildings of the University. It stands behind the existing Chemical Institute building of the University, and communicates with this on the basement level. The basement contains a dynamo room, a battery room, a store, a large electric furnace room, and a research room for four students. The generating machinery will comprise an 80 kw. alternator, with two windings, to give 1000 ampères at 80 volts, or 500 ampères at 150 volts; a 30 kw. direct current generator supplying current at 80—100 volts.; and a 10 kw. charging set for the batteries. The generating machinery is to be driven by current taken from the town mains at 400 volts pressure, each dynamo having a direct coupled motor on the same bed-plate. The battery room is to receive a battery of 36 Tudor cells, arranged in six sets of six cells each. The current from these will be employed for electrochemical work demanding low voltage. An 80 kw. electric furnace is to be installed in the large furnace

room in the basement. The first floor of the building contains a lecture theatre, with accommodation for between 80 and 90 students, a library, a photographic room, a workshop, and a preparation room for the lecture experiments. The students' large laboratory, with accommodation for 21 students, is located on the second floor, and, in addition, the research rooms for advanced students and for members of the staff, and the balance and instrument store rooms will also be found on this floor of the building. The third floor of the building contains a laboratory for the senior students and five rooms which will be chiefly devoted to research work, whilst the flat roof of the building is also planned to give additional accommodation for students, when required, for certain classes of experimental work. The working benches for the students in the two main laboratories and in the research rooms will be provided with gas, water, and electricity supply. The draught cupboards and general ventilating shafts throughout the building are served by gas burners, it being considered unnecessary to arrange for mechanical ventilation by exhaust fans. The main lighting of the buildings is by brackets or pendants carrying incandescence gas burners; but the fume chambers and certain of the rooms will be lighted by tantalum lamps. Prof. F. G. Donnan is in charge of the new laboratory.

On Oct. 13, the laboratory was formally presented to the University by Mr. Muspratt, and then declared open by Sir William Ramsay. The gift was acknowledged by the Vice-Chancellor of the University, and an address was given by Sir William Ramsay on the value and importance of research work in scientific training. He pointed out that the highest purpose of a University must be to make young men and women acquire the habit of conscious thought, and that the occupant of a chair of physical chemistry finds much difficulty in getting students to think for themselves—a task which could be best achieved through the medium of research work. The study of organic and inorganic chemistry elsewhere in the University should, of course, not be neglected by those who would work in the new laboratory. Prof. Ostwald, of Leipzig, gave a lecture later in the day on the "Relation of New Facts to the Older Theories of Chemistry," in which he showed how much better it would seem to be to introduce the study of chemistry by means of simple examples of Willard Gibbs's phase rule, than through, as at present, the ill-defined and difficult notions of molecules and atoms. In isolating any substance, the chemist had to work upon bodies, apparently homogeneous, such as solutions, and endeavour to resolve them, more and more nearly, but never completely, into so-called pure substances, which are unattainable limits. Thus, for example, he can resolve aqueous alcohol more and more accurately into pure alcohol and pure water as limiting substances, without ever actually obtaining either of these unchemical entities. On the following evening, the Liverpool Section of the Society of Chemical Industry received as guests at dinner in the University Club House the English and foreign visitors. Dr. Conroy, Chairman of the Section, presided, and the President of the Society, Mr. Eustace Carey, was also present. It is not without interest that both Mr. Muspratt, the donor of the laboratory, and Sir William Ramsay, who opened it, are Past Presidents of the Society of Chemical Industry.

EXAMINATIONS IN CHEMICAL TECHNOLOGY.

The Institute of Chemistry of Great Britain and Ireland has adopted a scheme for periodical examinations of its Fellows and Associates in the principles and practice of chemical technology, with the object of encouraging them to acquire a fuller, a wider and more thorough knowledge of the subject. Knowledge of such matters as the following is required of the candidate:—

The application of well-known chemical and physical laws to industrial operations; the development, control, and transmission of power and heat; a working knowledge of operations and plant in general industrial use, also of treatment and handling of materials; the properties of materials affecting their application to the construction of plant and apparatus in chemical works; some ability in interpreting drawings and in making dimensioned, rough sketches; the calculation of working costs, and a general knowledge of the clerical work connected with manufacturing operations. Questions which might involve the disclosure of unpublished processes and details of plant in particular works are not put. The present Board of Examiners consists of Ludwig Mond (Chairman), David Howard (Deputy Chairman), George Beilby, Bertram Blount, Charles C. Carpenter, R. Forbes Carpenter, Edward Divers, Percy F. Frankland (President of the Institute), Oscar Guttmann, Julius Lewkowitsch, Raphael Meldola, Edmund J. Mills, H. R. Procter, A. Gordon Salamon, and J. Millar Thomson. The first examination was held in October, and lasted three days. One candidate out of three passed the examiners. In addition to the Board of Examiners, Dr. Harold G. Colman specially examined candidates in gas manufacture, and Messrs. F. W. Harbord and John E. Stead in steel manufacture; Dr. Lewkowitsch, a member of the Board, specially examined in the oils and fats industry.

Journal and Patent Literature.

I.—PLANT, APPARATUS, AND MACHINERY.

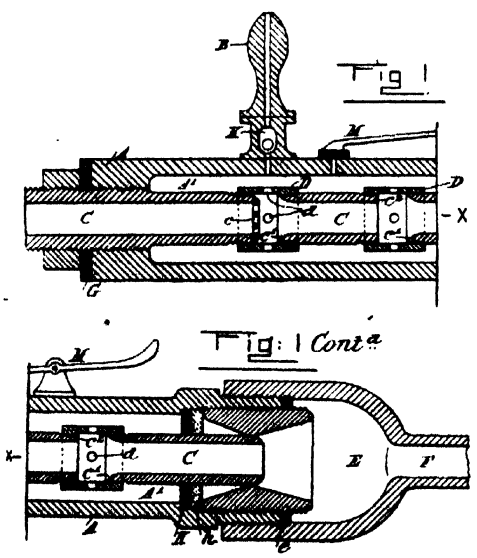
(*Continued from page* 1032.)

English Patents.

Heat interchanging or temperature equalising apparatus. A. E. A. Birk, Copenhagen. Eng. Pat. 18,321, Sept. 11, 1905.

The apparatus consists of a coil of tubes, the convolutions of which touch one another throughout their entire length. The liquid or gas to be heated or cooled flows through or over the coil in one direction, and the heating or cooling medium flows over or through the coil in the contrary direction, so that the counter-current principle is fully made use of. The liquid which flows over the coil is fed from a distributor on to a corrugated cooling plate, from which it flows on to the coil, and the other gas or liquid is forced through the coil under pressure, so that the whole of it has to traverse the entire length of the coil in order to obtain a maximum of efficiency. Two or more of these coolers may be combined into a series, and the pressures in the coils may be kept different to allow of a progressive effect. In this case, the connection between the separate coils is made by a suitable pressure-regulating valve. (Reference is directed to Eng. Pats. 3169 of 1887, 17,570 of 1891, 17,735 of 1895, 17,694 of 1902, and 3917 of 1904.)—W. H. C.

Cooling and drying moist air; Processes for continuously—— in large quantities, and plant for use in the same. C. Lean, London. From Maschinenbau Anstalt Humboldt, Kalk, Germany. Eng. Pat. 24,309, Nov. 24, 1905.



See Fr. Pat. 358,513 of 1905; this J., 1906, 270.—T. F. B.

Agitating apparatus for use in evaporating, distilling, emulsifying, gas-washing, pulping, and all similar industrial purposes. A. Z. Clark, Melbourne, Victoria. Eng. Pat. 3062, March 13, 1906.

An agitator furnished with propeller blades is rotated

in a horizontal plane partly within the lower end of an open-ended vertical cylinder, adjustably suspended in a tank or still, and a deflecting plate is arranged in the space in the tank around the cylinder to prevent circular motion of the contents. If the apparatus is to be used for gas-washing, the vessel is covered, and is provided with a bent inlet-pipe which passes centrally through the cover, and terminates just below the latter, within the suspended cylinder, which is in this case made of gauze or perforated plate. The annular space in the vessel is divided by a horizontal perforated plate which extends from the inlet-pipe at a point slightly above its lower end to the sides of the vessel, the cover of which is also furnished with an exit pipe.—W. H. C.

Vacuum; Apparatus for creating and maintaining a ——. A. J. Boult, London. From A. Manvers and H. Phillips, Sydney, N.S.W. Eng. Pat. 11,724, May 19, 1906.

The claim is for a small portable appliance which may be connected to any apparatus in which it is desired to produce a vacuum. It consists of an outer casing, A, which can be attached to the apparatus to be evacuated, by a nozzle, B, provided with a non-return ball-valve, K. Water under a pressure of at least 35 lb. to the square inch enters the compound inner tube, C, and is broken up into jets by the perforated cap, *c*. The tube, C, is made up of several parts connected by perforated sleeves, D, through the perforations, *d*, of which air is drawn from the annular space, A^1, by the jets of water. The mixture of air and water finally enters the expanded portion, E, which is screwed on to the end of the casing, A, and serves as a seal to prevent back-pressure of air from the escape pipe, F. The joints of the apparatus are made tight by the rubber washers, G, H, *e*, and the metal washer, *h*. The inlet ends, c^1, of the segments of the tube, C, have a trumpet shape and the outlet ends, c^2, a square shape as shown. Should water be drawn into the annular space, A^1, in consequence of any accident, the vacuum in A^1 can be destroyed by opening the valve, M.—W. H. C.

Centrifugal machines; Continuously operative ——. R. Haddan, London. From Aktiebolaget Separator, Stockholm. Eng. Pat. 16,000, July 14, 1906.

The claim is for a continuously operating centrifugal machine for separating solids from liquids. The drum is formed of a number of superposed, conical, perforated plates with solid plates interposed between them to guide the liquid. Modifications are claimed, in which the out flow openings are formed by parts engaging with and movable in relation to each other, or the solid and perforated plates may be in one piece with channels formed in the plate-body to allow the material to pass from the out-flow openings to the periphery of the drum.—W. H. C.

Centrifugal machines for drying or other purposes ——. R. Haddan, London. From Aktiebolaget Separator, Stockholm. Eng. Pat. 16,001, July 14, 1906.

The improvement consists in introducing supplementary discs between the usual ones. The material to be treated is introduced into the drum through the spaces between one side of the supplementary disc and the adjacent ordinary disc, and through the corresponding space on the other side any desired gaseous or liquid agents may be introduced to act on the material in the drum.—W. H. C.

United States Patents.

Muffle or furnace for annealing. A. Smallwood, Assignor to The Incandescent Heat Co., Ltd., London. U.S. Pats. 833,640 and 833,641, Oct. 16, 1906.

See Eng. Pat. 18,877 of 1905; this J., 1906, 1049.—T. F.B.

Separator; Centrifugal ——. J. J. Berrigan, East Orange, N.J., Assignor to F. J. Arend, New York, and J. Bernstrom, Stockholm. U.S. Pat. 834,043, Oct. 23, 1906.

The material to be separated is introduced through an axially-mounted feed tube, fitted with a worm conveyor, and discharging through a lateral opening rotating with the horizontal rotary separating vessel. The outlet for the separated liquid portion is arranged between the circumferential wall and the axis of the vessel, whilst the solid portion, deposited in the vessel, is removed to a discharge opening by means of a spiral conveyor mounted on a cage which surrounds the feed tube inside the vessel, and is rotated at a rate of speed different from that of the vessel itself.—C. S.

Pyrometer; Electrical-resistance ——. E. F. Northrup, Philadelphia, Pa. U.S. Pat. 834,162, Oct. 23, 1906.

The pyrometer comprises a porcelain tube, a low-resistance temperature-measuring conductor mounted inside and near one end of this tube, supports for the conductor, separate insulating tubes, inside and nearly as long as the porcelain tube, and enclosing current leads and potential leads connected with the resistance conductor; a head receiving one end of the porcelain tube, and fitted with terminals for the potential and current leads, and an outer metal tube, surrounding the porcelain tube near the head, and fitting into a metal cap secured to the face of the head.—C. S.

French Patents.

Crucibles of sand and lime; Process for the manufacture of ——. S. W. Berglund. Fr. Pat. 366,830, April 27, 1906.

The mixture of sand and lime, to which other materials, such as cement, may be added, is brought into the moulds in a state of suspension in water, and submitted to pressure without removing the water. The pressure may be applied at temperatures above 100° C.—A. G. L.

Filter; Recuperative ——. M. Lamort. Fr. Pat. 366,807, June 2, 1906.

The liquid to be filtered is placed in a vessel, through the perforated bottom of which it descends on to a movable endless belt of wire gauze, which is caused to oscillate continuously. The solids separated from the liquid are discharged into a suitable receptacle. The liquid adhering to the under side of the gauze is removed by contact with blades of wood arranged below the belt.—C. S.

Vacua; Process and apparatus for obtaining high ——. F. Soddy. Fr. Pat. 367,587, June 30, 1906.

See Eng. Pats. 17,923 of 1905, and 5348 and 5349 of 1906; this J., 1906, 992 and 853.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 1035.)

Coals; Determination of calorific value of —— *by the Parr calorimeter.* E. J. Constam and R. Rougeot. Z. angew. Chem., 1906, **19**, 1796—1806.

The authors have measured the calorific values of a large number and variety of coals by Parr's method, and have investigated the effect of a number of details in the working, comparing the results with those obtained from the same coals with the Mahler bomb. The chief conclusions are as follows:—(1) The factor to be used (no. of calories corresponding to 1° C. observed rise of temperature in the instrument) is, with the same coal, variable with the quality (content of sodium peroxide and of water) and with the coarseness of grain of the sodium peroxide used, and also according as correction for loss of heat by radiation is or is not made. The variation from these causes may amount to 3 per cent. of the total value. (2) The magnitude of other errors renders it superfluous to correct for loss of heat by radiation. (3) The difference between the Parr result and the Mahler result is not greater when ordinary high-grade commercial peroxide is used than when the peroxide is finely powdered; the closest agreement is obtained by using excess of finely-ground peroxide, together with potassium persulphate. In no circumstances, however, have the authors ever obtained complete combustion of a sample of coal in the Parr calorimeter, and they do not regard its results as sufficiently trustworthy to serve as basis for a decision as to the calorific value of a coal.—J. T. D.

Naphthalene from coal gas; Removal of ——. A. H. White and J. M. Barnes. J. Gas Lighting, 1906, **96**, 181—183; 244—245; 324—326.

In continuation of the investigation of White and Clary on this subject (this J., 1906, 59) the authors have further investigated the effect on the naphthalene content of the gas, of the removal of the suspended tar from the crude gas. The experiments were carried out at different works by analysing the gas at the inlet and outlet of the Pelouze-Audouin tar separator, placed in all cases between the primary and secondary condensers, *i.e.*, before the gas had been completely cooled, and at the same time a sample of the gas from the inlet was treated for the complete removal of the tar by means of a specially-constructed centrifugal separator, the gas passing from this apparatus being also analysed. The results obtained show that the separation of the suspended tar, whether by the Pelouze or the centrifugal separator, simultaneously effects the removal of a considerable proportion of the naphthalene vapour from the gas, although no material reduction of temperature occurs during the separation. The authors believe that this reduction is due to the fact that in the process of separation the gas is brought into intimate contact with the tar, thus enabling the latter to effect its full solvent action on the naphthalene still present as vapour in the gas. The amount of naphthalene left in the gas, however, becomes greater as the temperature at which the gas passes through the separator increases. Whilst in most cases it is found that the complete or nearly complete removal of the suspended tar is advantageous, experience at one works examined, has shown that, under the particular conditions prevailing there, such complete removal is undesirable, as, if carried out, stoppages from deposited naphthalene quickly occur in the secondary condenser and scrubbers, which are obviated by working the Pelouze-Audouin separator in such a manner as only to remove a portion of the suspended tar. The exact causes of the abnormal results at this works have not yet been elucidated. The authors find that it is impossible to obtain from large mains a true average sample of crude gas containing suspended tar, the amount of the latter being about three times as great near the edge as at the centre of the main. Further tests have been made with regard to the absorption of naphthalene by solvents at high temperatures, and it is shown that under suitable conditions heavy tar, pitch, and even the so-called "free carbon" of coal-tar all absorb considerable quantities of naphthalene, the amount absorbed under the conditions of the experiment increasing with rise of temperature. The authors also reply to some of the criticisms made upon their previous paper (this J., 1906, 60).—H. G. C.

Steam; Dissociation of ——. I. H. v. Wartenberg. II. W. Nernst and H. v. Wartenberg. VII., pages 1093 and 1094.

Carbon dioxide; Dissociation of ——. W. Nernst and H. v. Wartenberg. VII., page 1094.

Water vapour and carbon dioxide; Dissociation of —— *at high temperatures.* I. Langmuir. VII., page 1094.

English Patents.

Fuel; Combustible gaseous —— *for the generation of motive power.* G. M. S. Tait, New York. Eng. Pat. 9501, April 23, 1906.

Air, substantially free from moisture, is passed without the admixture of steam through a deep bed of fuel (say 3 ft. to 5 ft.), so as to produce a gas consisting substantially of carbon monoxide and nitrogen, with less than 5 per cent. each of carbon dioxide and hydrogen. The cooled and purified gas is mixed with air in predetermined proportion in the cylinder of a gas engine, compressed to between 11 and 16 atmospheres, and then ignited. It is claimed that the elimination of hydrogen from the gas, leads to increased efficiency, owing to the high compression thereby rendered permissible. If the fuel used be coal, or other clinkering material, a mixture of air and carbon dioxide or gaseous products of combustion, may be used instead of pure air; the endothermic reaction of the carbon dioxide upon the carbon thus reduces the temperature and prevents clinkering.—H. B.

Coke ovens. W. Klönne, Magdeburg, Germany. Eng. Pat. 21,135, Oct. 18, 1905.

See Fr. Pat. 358,624 of 1905; this J., 1906, 309.—T. F. B.

Carburetted air apparatus. T. H. Glasscoe, Wanstead, Essex. Eng. Pat. 14,226, July 10, 1905.

The carburetter is constructed in sections, each provided with its own air-inlet and gas-outlet valves, these being so connected to the bell of the gas-holder that the number of sections in operation is controlled by the movements of the bell. Each section is fitted with a jacket through which hot water or other heating fluid can be passed, the admission valves being likewise controlled by the movements of the gas-holder bell, so that only the sections in operation are heated. Thermostatic devices are also used in connection with the air valves, so as to counteract the influence of changes of temperature upon the richness of the carburetted air produced.—H. B.

Furnaces used in connection with gas retorts. J. H. Brown, Nottingham. Eng. Pat. 18,723, Sept. 16, 1905.

In a generator for heating gas retorts, having a series of overlapping flat bars under its charging inlet, the level grate at the foot of the said step-like arrangement of bars, and the door at the front of the same, are dispensed with.—H. B.

Gas generators; Suction ——. J. G. L. Bormann, Charlottenburg, Germany. Eng. Pat. 7499, March 28, 1906.

See U.S. Pat. 817,035 of 1906; this J., 1906, 421.—T. F. B.

Ferrocyanides; Manufacture of —— *from gas-purifying masses or other ferrocyaniferous masses.* T. Bollowitsch. Eng. Pat. 8362, April 6, 1906. VII., page 1095.

Gases; Process for removing sulphide of hydrogen from ——. E. Burschell, Landau, Bavaria. Eng. Pat. 11,133, May 12, 1906.

See Fr. Pat. 366,047 of 1906; this J., 1906, 976.—T. F. B.

Metals; Increasing the electrical resistance of —— *[for use in electric incandescence lamps].* H. Kuzel, Baden, Austria. Eng. Pat. 7655, March 30, 1906. Under Int. Conv., July 26, 1905.

SEE Fr. Pat. 364,613 of 1906; this J., 1906, 920.—T. F. B.

Electrical incandescence bodies; Method of producing metallic [tungsten] ——. Deutsche Gasglühlicht A.-G. (Auerges.), Berlin. Eng. Pat. 14,901, June 30, 1906. Under Int. Conv., Oct. 28, 1905.

IN order to obviate the distortion which occurs when metallic electrical glow-bodies, during their manufacture, are heated white hot in suitable gases by the electric current, the process is so conducted that, when an alternating current is used, its periodicity is increased to, say, 100, or the form of curve of the current is selected so as to make the periodic fluctuations of temperature less than in the case of the usual, approximately sinus-formed, alternating current having a periodicity of 60 or less. When a continuous current is used, the influence of the magnetic field permeating the workroom is eliminated or corrected, as, for instance, by enclosing the room in an iron casing, by compensating the magnetic field by a suitable additional field, by setting the loops of filament perpendicular to the horizontal components of the magnetic field, or by changing the position of the filament during the operation, so that the terrestrial magnetism exerts a twist in the opposite direction to what it did before.—H. B.

UNITED STATES PATENTS.

Furnace gases; Apparatus for purifying and re-heating ——. D. Lamond, Pittsburg, and D. D. Lamond, Allegheny, Pa. U.S. Pat. 833,467, Oct. 16, 1906.

THE apparatus consists of a series of communicating settling chambers arranged within a series of communicating hollow walls; means for admitting impure gas to the first chamber of the series; a gas washer communicating with the last chamber of the series; a connection for passing the washed gas through the series of hollow walls (beginning with the last of the series), in order to reheat the gas; and an outlet for the purified and heated gas from the hollow wall of the first chamber of the series. —C. S.

Coke and gas; Process of producing ——. F. Logan, Phœnixville, Pa. U.S. Pat. 833,471, Oct. 16, 1906.

THE oven (see U.S. Pat. 833,611; following abstract) is charged with coal, and when the charge is hot enough for coking off, steam is admitted below. The resulting water-gas is mixed, in the oven, with gas distilled from coal in another, and with oil-gas generated simultaneously in the first oven, the mixed gas being then drawn off to the gasometer.—C. S.

Coke and gas; Apparatus for making ——. F. Logan, Phœnixville, Pa. U.S. Pat. 833,611, Oct. 16, 1906.

A NUMBER of coke ovens, each with a perforated bottom or grate, and a steam inlet below, and an oil inlet above the same, are connected together by means of a pipe extending through their upper walls, and fitted with valves between the ovens. A valved pipe leads from the ovens to a suction fan for withdrawing the gas.—C. S.

Retort; Vertical —— for the destructive distillation of coal. H. W. Woodall, Wimborne, Assignor to A. M. Duckham, Parkstone. U.S. Pat. 833,861, Oct. 23, 1906.

SEE Eng. Pat. 21,447 of 1905; this J., 1906, 306.—T. F. B.

Gas; Method of producing ——. J. S. Smith, Chicago, Ill. U.S. Pat. 833,182, Oct. 16, 1906.

THE gas is passed from a generator up through a carburetter, and from the top of this to a second carburetter, down which it also passes. At or near the bottom of the second carburetter a portion of the descending gas is returned through a passage at the bottom of the carburetters to the first carburetter, whilst the remainder of the gas passes on to its destination. The returned portion of the gas passes up through the first carburetter together with gases coming from the generator, and on its way is mixed with steam or oil or both. (See following abstract.)—W. C. H.

Gas-producing apparatus. J. S. Smith, Chicago, Ill. U.S. Pat. 833,256, Oct. 16, 1906.

IN this apparatus, the generator is provided with a cone that forms the upper part of its combustion chamber, and supports some chequer-work, which is surrounded by a supplementary combustion chamber. Means are provided for supplying hydrocarbons to both combustion chambers, and also air and steam to either. The gas from the generator enters the first of a series of two or more carburetters at or near the bottom, and passes up the carburetter to the top, and thence through a passage to the top of the second carburetter. The carburetters are also connected at their lower ends by a passage, in which is a fan or other means for inducing the return of a portion of the gas which has passed down the second carburetter, to the first. The lower part of the second carburetter is provided with a gas-discharge pipe, connecting it with the scrubber.—W. C. H.

Gas; Method of producing heating and illuminating ——. J. S. Smith, Chicago, Ill. U.S. Pat. 833,346, Oct. 16, 1906.

GAS-producing materials, oil, steam, and air are forcibly conducted through a decomposing degree of heat in a generating chamber, and then subjected to a violent impact, whereby their molecules are finely divided, and concurrently subjected to an amount of heat sufficient to dissociate their vapours. These vapours are then confined in the presence of the heat, until re-associated into a volume of fixed gas. When this gas is discharged from the retort, additional steam is forcibly delivered across the path of the gas, with a violent impact, by which means the molecules become finely divided in the presence of a degree of heat sufficient to dissociate the steam into gases, which become thoroughly mixed with the gases generated in the earlier part of the process, and the heats of generation produced are utilised for maintaining a decomposing temperature in the generating chamber. A heating and illuminating gas, containing an excess of oxygen and hydrogen, derived from the decomposed steam, is thus continuously produced. (See also U.S. Pats. 817,279 and 817,280 of 1906; this J., 1906, 465.)—W. C. H.

Gas; Apparatus for producing hydro-oxygen ——. A. Lang and H. F. Smith, Assignors to C. H. Zink, Philadelphia, Pa. U.S. Pat. 833,399, Oct. 16, 1906.

THE apparatus described has a chamber with which are connected two others, one an air and the other a gas chamber. Each of these can be heated by separate burners, connected with the first-mentioned chamber, which is beyond the heat zone of the burners, *e.g.*, below them. Air under pressure is supplied to the air chamber, where it is superheated, and the gas can be similarly superheated in its chamber, the supplies of air and gas to the chambers being under separate control. The heated air and gas mix in the first-mentioned chamber, from which the new gas is led to a desired point for use.—W. C. H.

Gas; Method of producing ——. A. Lang and H. F. Smith, Assignors to C. H. Zink, Philadelphia, Pa. U.S. Pat. 833,400, Oct. 16, 1906.

THE method of producing a new and distinct gas consists in superheating a hydrocarbon gas, and leading this in its heated condition into a chamber, where it is mixed with air, supplied under pressure, and superheated or not. The product of the union of the heated gas and air may also be highly heated in the chamber in which they unite.—W. C. H.

Gas producers; Means for maintaining heat in ——. E. Capitaine, Frankfort on Maine, Germany. U.S. Pat. 833,673, Oct. 16, 1906.

SEE Fr. Pat. 353,065 of 1905; this J., 1906, 901.—T. F. B.

inert atmosphere (or, when oxygen or sulphur compounds are used, in a reducing atmosphere). The connections between the filaments and the supply conductors may be made of similar plastic materials, in a thinner paste, which is heated to a white heat in a neutral or reducing atmosphere. (See also Eng. Pats. 15,462 of 1905 and 8057 of 1906; this J., 1906, 307; 841; and Fr. Pat. 364,613 of 1906; this J., 1906, 920.)—W. C. H.

Luminous bodies for electric incandescence lamps; Process of making ——. H. Kusel. Third Addition, dated April 3, 1906, to Fr. Pat. 359,025, Jan. 9, 1905. Under Int. Conv., Aug. 3, 1905.

See Eng. Pat. 8057 of 1906; this J., 1906, 841.—T. F. B.

Luminous bodies of tungsten for incandescence lamps and their mode of manufacture. Consortium für Elektrochem. Ind., G.m.b.H. Fr. Pat. 367,009, June 9, 1906. Under Int. Conv., July 5, 1905.

By this invention, a tungsten body, suitable for use as a filament in incandescence electric lamps, is obtained by heating the tungsten, preferably by electrical means, almost to its fusing point, in an inert atmosphere, prior to its introduction into the lamp. The claims also include bodies obtained by this process.—W. C. H.

Illuminating metallic bodies for incandescence electric lamps; Process of manufacture of ——. Deutsche Gasglühlicht A.-G. (Auergesellschaft). Fr. Pat. 367,033, June 9, 1906.

This patent is for a process of manufacturing illuminating metallic bodies for incandescence electric lamps, that shall be of uniform size and suitable shape, and consists in heating to redness, by an electric current, the threads, bent into the form of a stirrup, after they have been finished, and in stretching them by a force applied to the lower part of the stirrup.—W. C. H.

Incandescence bodies for electric lamps. Consortium für Elektrochem. Ind., G.m.b.H. Fr. Pat. 367,045, June 11, 1906.

This patent is for an incandescence body for electric lamps, supplied preferably with an alternating current, and burning *in vacuo*, or in inert gases. The body is composed of a conductor of the second group, such as thoria, zirconia, yttria, &c., and a metal, in this case, tungsten or an alloy of it. In order to obtain as fine a division and as intimate distribution as possible of the tungsten in the conductor of the second group, compounds of the two constituents are first produced by heating them together (for example, a tungstate of thorium is formed), and these compounds are afterwards heated in a reducing atmosphere, by which means metallic tungsten and the conductor of the second group are re-obtained in a finely divided and intimately mixed condition.—W. C. H.

Incandescence bodies of high illuminating power; Process for making strong ——. H. C. Albrecht. Fr. Pat. 367,028, June 25, 1906.

See Eng. Pat. 15,295 of 1906; this J., 1906, 877.—T. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 1036.)

Fats and mineral oils; Cholesterol content of ——, *and probable genetic connection between them.* M. A. Rakusin. Chem.-Zeit., 1906, **30**, 1041—1042.

Among animal oils, fish-liver oil and lanolin give the cholesterol reactions, and their optical activity is probably mainly due to that substance or an isomeride of the same. He assumes that almost all mineral oils of high boiling point also contain cholesterol products, the colour reactions in some cases being almost identical with those of fish-liver oil; and the cholesterol content seems to increase with the sp. gr., boiling point, and viscosity of the distillate, the percentage being ascertainable colorimetrically when the tests are performed quickly. The optical activity is a less decisive proof in the case of mineral oils, since it is also a characteristic of the naphthenic acids. American lubricating oils appear to give clear indications of racemised cholesterol products, the reactions being quite as intense as those of Caucasian oils having eight times the rotatory power. This fact is considered to be of great importance in connection with the physico-chemical geology of mineral oils. The author regards the presence of cholesterol as suggestive of the organic origin of petroleum in oilfields where it may occur, collateral circumstances pointing to a mixed animal and vegetable origin. The low optical activity of Pennsylvania petroleum derivatives can only be attributed to the presence of racemised cholesterol. No artificially prepared petroleum can be considered identical with the natural oil unless it exhibits optical activity, opacity to the polarised ray in dilute solution, the reactions for cholesterol, and the phenomenon of dichroism, even though only manifest in dilute solutions. The presence of organogens (oxygen in the form of cholesterol and naphthene acids, and sulphur, phosphorus, and nitrogen as organic bases) in many mineral oils should not be under-estimated. The possession of the first three essential properties seems to be of great importance for the geology of petroleum, and in conjunction with "Day's filtration phenomena," is considered to afford valuable information on the relative geological age of mineral oils, and on the conditions of deposition in a given field.—C. S.

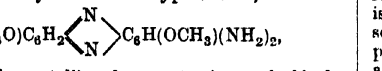
French Patent.

Lubricant for machine parts, &c. L. A. A. Hennequin and G. J. B. Cayeux. Second Addition, dated May 29, 1906, to Fr. Pat. 350,090, Aug. 1, 1904. (See Eng. Pat. 11,679 of 1905; this J., 1905, 1008.)

Approximately equal quantities of powdered camphor and naphthalene are mixed together, and 60—125 grms. of this mixture are dissolved in 1 litre of petroleum.—C. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 1038.)



Aminoalizarins; Derivatives of ——. G. Schultz and I. Erber. J. prakt. Chem., 1906, **74**, 275—296.

On boiling α-aminoalizarin with acetic anhydride in excess the diacetyl derivative is obtained. This forms reddish-brown leaflets, melting at 245° C., dissolves in glacial acetic acid, chloroform, and toluene, is sparingly soluble in benzene and acetone, and almost insoluble in ether. Moderate action with acetic anhydride leads to the formation of an isomeric diacetyl derivative, which crystallises from alcohol in yellow lustrous needles, melting at 205° C. The benzoyl derivative obtained by heating a suspension of the α-base in nitrobenzene with benzoyl chloride forms reddish-brown needles, melting at 310° C. It is almost insoluble in alcohol and ether, sparingly soluble in other media, and remains unchanged when boiled with hydrochloric acid. The action of benzoyl chloride in excess leads to the formation of a dibenzoyl derivative, which crystallises in light brown needles melting at 255° C. The benzoylation of the β-base gives rise to the formation of a dibenzoyl derivative crystallising in matted yellow needles, which melt at 252° C., and are changed into the mono-derivative melting at 275° C. when dissolved in strong sulphuric acid. Diazotisation of α- and β-aminoalizarin leads to the formation of corresponding diazo derivatives. The diazonium compound of the α-base yields purpurin by sublimation, whilst the β-diazo compound decomposes when similarly treated. On boiling the latter with alkalis a red solution is obtained, which, when acidified, gives a brown precipitate yielding alizarin by sublimation. Attempts to prepare dyestuffs gave negative results in the case of the α-diazonium salt; β-diazoalizarin, however, was found to interact with β-naphtholdisulphonic acid R in alkaline

solution to form a product possessing dyeing properties, although only to a slight extent. When *α*-aminoalizarin is heated with sulphuric anhydride, 1.2-dihydroxy-4-aminoanthraquinone-3-sulphonic acid is obtained, which gives purpurin- and alizarinsulphonic acids on diazotisation.—D. B.

3.4-*Diaminoguaiacol; Note on* ——, [*Formation of an azine dyestuff*]. F. Fichter and J. Schwab. Ber., 1906, **39**, 3339—3341.

4-AMINOGUAIACOL, on acetylation and nitration, yields, after elimination of the acetyl groups, 3-nitro-4-aminoguaiacol melting at 169°—171° C., which on reduction gives the *o*-diamine, 3:4-diaminoguaiacol. When a current of air is passed through the aqueous solution, 2:3-diamino-8-hydroxy-1:9-dimethoxyphenazine,

$$(HO)(CH_3O)C_6H_2\begin{matrix}N\\ \diagup\diagdown\\ N\end{matrix}C_6H(OCH_3)(NH_2)_2,$$

is obtained, which crystallises from water in nearly black, glistening needles. The substance gives a green solution with concentrated sulphuric acid, which on dilution with water turns successively blue, violet, and red. The aqueous solution is brown-red, and on addition of alkalis becomes reddish-yellow. The brown-red alcoholic solution has a green fluorescence. Animal and vegetable fibres are dyed brownish-red from a bath acidified with acetic acid.

—J. C. C.

Triphenylmethyl. XV. M. Gomberg and L. H. Cone. Ber., 1906, **39**, 3274—3297.

A LARGE number of halogen-substituted derivatives of triphenylmethyl chloride have been prepared, which by the action of molecular silver in benzene solution and in absence of air give rise to coloured substances. The *o*-substituted derivatives acquire the deepest shades, and the phenomena correspond with the variation in colour observed by Noelting consequent on the introduction of halogen in the *o*-position of the phenyl group in Malachite Green. By the action of silver the "carbinol chlorine" is removed, and on exposure of the coloured solution to the air, the colour disappears and peroxides are formed. In the case of the *p*-substituted derivatives, however, if the action of the silver be continued so as to remove as much halogen as is possible by this means, the colour is not thereby diminished, but is lost on exposure to the air, peroxides in this case, not being formed. The authors consider that these coloured compounds, obtained by removal of the "carbinol chlorine," must possess the same constitution as triphenylmethyl itself, as they yield peroxides of the same type as does the latter. There must be a very close similarity in the constitution of the stable triphenylmethane dyestuffs and the unstable coloured substances here described. The origin of colour in the latter must be due to one of the phenyl groups assuming a quinonoid structure; and, as the colour of the triphenylmethane dyestuffs is attributed to the similar behaviour of one of the phenyl groups, the hypothesis of a quinonoid structure for these colouring matters receives direct experimental support from the foregoing researches.—J. C. C.

Benzidinedisulphonic acid; Constitution of Griess' ——. G. Schultz and W. Kohlhaus. Ber., 1906, **39**, 3341—3345.

BENZIDINEDISULPHONIC acid, prepared by Griess by treating benzidine with fuming sulphuric acid, was diazotised, and the diazo-group eliminated by alcohol, whereby diphenyl-3:3′-disulphonic acid was obtained. The free acid is a yellow, syrupy mass; the potassium salt crystallises from water in colourless leaflets containing two molecules of water of crystallisation. On fusion with potash, 3:3′-dihydroxydiphenyl resulted which was identical with the compound known to possess that constitution. Hence Griess' benzidinedisulphonic acid is 4:4′-diaminodiphenyl-3:3′-disulphonic acid.—J. C. C.

Benzidine; Oxidation of —— [*Azo dyestuffs*]. R. Willstätter and L. Kalb. Ber., 1906, **39**, 3474—3482.

BY the oxidation of benzidine with silver oxide or lead peroxide in presence of an indifferent solvent, the authors had previously observed the formation of a substance crystallising in yellowish-red needles which easily yielded benzidine on reduction (this J., 1905, 432). It is now shown that this consists of diaminoazodiphenyl, $NH_2.C_6H_4.C_6H_4.N_2.C_6H_4.C_6H_4.NH_2$. The exact behaviour of benzidine towards oxidising agents is as follows:—(1) In neutral solvents—An ethereal solution of benzidine shaken with lead peroxide becomes brownish-yellow; on adding very dilute acetic acid to a filtered portion and shaking, an indigo-blue coloration is produced which on further addition of acid turns violet. This colour reaction can only be due to the presence in the solution of di-imino-diphenyl $NH:C_6H_4:C_6H_4:NH$, which is probably the first product of oxidation of benzidine in the above reaction, and which, by the coalescence of two molecules, is rearranged into diaminoazodiphenyl. (2) In aqueous solution—On adding lead peroxide or a solution of permanganate to a solution of benzidine in dilute acetic acid, a deep indigo-blue coloration is produced; with more of the oxidising agent this becomes pure yellow. Both solutions are unstable, the former gradually becoming violet-red (especially with acids), and the latter turning blue and finally colourless, a dark precipitate being formed. Probably the yellow solution contains the di-imonium salt, and the blue an intermediate product of a quinhydrone character. The diaminoazodiphenyl produced in the above-mentioned way was identical with the substance prepared synthetically as follows:—1 grm. of 4-nitro-4′-aminodiphenyl was dissolved in 250 grms. of alcohol, and a mixture of 150 grms. of water and 75 grms. of a 33 per cent. caustic soda solution added. Five grms. of zinc dust were now shaken with the hot liquid until the colour disappeared. The mixture was boiled for a short time, until the air was expelled from the flask, and filtered. The filtrate rapidly became orange, and the oxidation was completed by a stream of air; 0·4 grm. of diaminoazodiphenyl separated in yellowish-red microscopic needles which on crystallising from benzene melted at 287°C. The substance has practically no affinity for the fibre; wool and silk are dyed a faint brown, which, however, disappears on washing. The tetrazochloride was prepared by grinding the hydrochloride of the base (4 grms.) with 400 c.c. of 1 per cent. hydrochloric acid, cooling, and shaking with a large excess of sodium nitrite (40 c.c. of a 10 per cent. solution). The resulting clear solution, on standing for half an hour in ice, began to deposit the tetrazochloride, which was completely precipitated by the addition of 40 c.c. of concentrated hydrochloric acid, and allowing to stand a further half-hour. Prismatic crystals with a violet reflex were obtained which, on powdering, became orange-red. The substance contains 2 mols. of water of crystallisation This tetrazochloride is a substantive cotton dyestuff, and also dyes silk remarkably well. A 1 per cent. solution dyes mercerised cotton from a cold bath ochre-yellow, silk fiery orange. The dyestuff has so great an affinity for silk that the bath is exhausted in 15 minutes. The dyeings are fast to soaping, alkalis, acids, and boiling. The dyestuff produced by combining the tetrazo-salt with 2 mols. of naphthionic acid is less substantive than Congo Red and of little value.—J. C. C.

Azo dyestuffs; Heats of combustion and constitutional formulæ of ——. P. Lemoult. Compt. rend., 1906, **143**, 603—605.

RESULTS of determinations of the heat of combustion of a number of azo-dyestuffs confirm the azoic ($RN:N.C_6H_4.NH_2$ or OH) rather than the quinonoid ($\begin{matrix}R\\ H\end{matrix}>N.N:C_6H_4:NH$ or O) formula for these substances.

—J. T. D.

Quinone-azine. R. Willstätter and M. Benz. Ber., 1906, **39**, 3482—3491).

THE authors have studied the behaviour of *o*- and *p*-amino and hydroxy-derivatives of compounds, consisting of two benzene rings united by groups, capable of yielding quinones, towards silver oxide or lead peroxide in benzene solution. *Oxidation of aroplenol.*—A solution of 5 grms.

of *p*-azophenol containing water of crystallisation, in 1 litre of ether, was shaken mechanically with silver oxide prepared from 15 grms. of silver nitrate (double the theoretical amount) and 10 grms. of anhydrous sodium sulphate. After a few minutes the liquid became green, and finally, after about an hour, deep orange-red. The end of the reaction was reached when a test gave no immediate precipitate on shaking with water and a little dilute ammonia, and adding a drop of lead acetate solution. On evaporation of the ethereal solution 2 grms. of quinone-azine $O:C_6H_4:N.N:C_6H_4:O$ were obtained, a further quantity being yielded by extracting the residue with chloroform. The total yield was about 90 per cent. of the theoretical. The oxidation of anhydrous azophenol proceeds much more slowly, and the use of lead peroxide offers no advantage. Quinone-azine is easily soluble in hot ethyl acetate, acetone, alcohol, or glacial acetic acid, sparingly so in the cold; it is also readily soluble in benzene or chloroform, sparingly so in ether, and nearly insoluble in light petroleum. It is only slightly soluble in boiling water, and may be crystallised from this solvent by boiling for a short time with a large quantity (2000:1), and quickly cooling. In general, however, quinone-azine is decomposed by water; on heating the aqueous-alcoholic solution a brown tar separates. Alkalis convert the substance into an amorphous black-green mass, and it is dissolved by acids with a carmine-red colour. The solutions of quinone-azine are much more intensely coloured than those of azophenol; ethereal solutions of the latter are pure yellow, whilst dilute solutions of the former are deep orange-red. Quinone-azine crystallises from organic solvents in two modifications, namely: in large, dark orange-red prisms or needles yielding a brick-red powder, and in dark-yellow rhombohedric leaves or tables, the powder of which is deep yellow. Both forms exhibit a blue reflex under the microscope. The substance is stable in the air, odourless, and non-volatile. On heating, it does not melt, but burns at 158° C., previously becoming dark. Its ethereal solution liberates iodine from iodine-starch solution and oxidises hydroquinone (quinol), converting it into the corresponding quinhydrone. The quinhydrone of quinone-azine crystallises in blue-black, bronzy needles, melting at 181°—182° C. from a solution of equimolecular quantities of quinone-azine and azophenol in ether. Quinone-azine is reduced by powerful reducing agents, such as aluminium amalgam, zinc dust, and water, or stannous chloride and hydrochloric acid to *p*-aminophenol, by sulphurous acid or phenylhydrazine to azophenol. This is, however, not identical with the azophenol from which the substance is derived (see succeeding extract). *Oxidation of p-dihydroxystilbene.*—2 grms of dihydroxystilbene were suspended in 500 c.c. of ether, and shaken for some hours with 25 grms. of lead peroxide. The lead residue which contained the product was heated for a short time on the water-bath with 500 c.c. of benzene and 50 grms. of peroxide. The quinone $O:C_6H_4:CH.CH:C_6H_4:O$ crystallised from the filtrate in brown needles. *p*-Azoaniline is not attacked by silver oxide in ethereal solution, and only very slightly by lead peroxide in benzene solution. In the preparation of this substance from diazoacetanilide and aniline, *p*-acetaminodiazoaminobenzene was obtained, which crystallises from an ethyl acetate solution on addition of light petroleum in orange-yellow needles melting at 150°—152° C. It is easily soluble in alcohol or ethyl acetate, sparingly so in ether or benzene, and only very slightly so in light petroleum. On saponification with sodium ethoxide, *p*-aminodiazoaminobenzene is obtained which crystallises from dilute alcohol in brownish-yellow needles, melting with decomposition at 157° C. It is easily soluble in alcohol, sparingly so in ether, and insoluble in light petroleum or water.—J. C. C.

Azophenols; Contribution to our knowledge of ——. R. Willstätter and M. Benz. Ber., 1906, 39, 3492—3503.

When quinone-azine (see preceding abstract) is reduced to *p*-azophenol a new modification results, which differs in many physical properties from that prepared in the ordinary manner, and from which quinone-azine is obtained by oxidation. The ordinary azophenol is called α, and the new modification β. The chief points of difference are shown in the following table:—

Properties.	α.	β.
Appearance of crystals.	Amber-yellow or light-brown tables	Reddish-brown tables with strong blue-reflex.
Colour of powder.	Dark yellow	Bluish brown-red
Colour of powder when heated	Chrome-green	Brick-red
Behaviour of heated powder with moist air.	No action.	Combines with 1 mol. of water
Solubility in benzene at 17 °C.	1:10800	1:1500

The two modifications have, however, so many properties in common that they are probably geometrical isomerides. Azophenol β is converted into α by distillation in a vacuum, but much decomposition occurs. Both varieties yield the same diammonium salt, and give the same addition compound with phenylhydrazine. *o*-Azophenol readily absorbs 1 mol. of ammonia, but when fused, sublimed in a vacuum, or distilled, passes into a condition in which no reaction with ammonia takes place. When, however, the stream of ammonia gas is passed over the latter modification in presence of aqueous ammonia, the ammonium salt is finally obtained.—J. C. C.

Azomethine dyestuffs; Influence of the carbon double linking on the colour of ——. R. Möhlau and R. Adam. Z. Farben-Ind., 1906, 5, 402—412. (See this J., 1906, 1037.)

A large number of azomethine dyestuffs has been prepared and their colour investigated by rubbing them in a finely-divided condition on coarse filter paper. The shades observed were compared on the "Radde" international colour scale. The characteristic colorations obtained with concentrated sulphuric acid were useful in indicating the influence of the various chromophore and auxochrome groups on the tinctorial properties. The results are shown in the following table:—

Components. Aldehydes.	Amine	Colour on Radde scale.	Colour in concentrated H_2SO_4.
Benzaldehyde	*p*-aminodimethylaniline.	8 r	colourless
Cinnamic aldehyde		7 m	pale yellow

Dimethyl-*p*-aminocinnamic aldehyde		26 l	dark yellow

The conclusions drawn are: (1) the influence of the —C:C— group on the shade of azomethine compounds can in each case be detected. (2) When the nitro-group is present in the aldehydic component an increase in colour is produced. The *p*-position of the nitro-group exerts the greatest influence, the *o*-position rather less, and the *m*-position the least. The influence of the auxochrome dimethylamino-group in the aldehydic component is weaker than that of the chromophoric nitro-groups in the same relative position. (4) The auxochrome groups, OH and $N(CH_3)_2$, contained in the amino-component likewise produce an increase in colour, the latter group to the greater extent. Among the hydroxy-compounds the OH-group exerts the greatest influence when it is in the ortho-position.—J. C. C.

Bixin, the dyestuff of Bixa Orellana; Studies on ——. I. L. Marchlewski and L. Matejko. Anz. Akad. Wiss. Krakau, 1905, 745—753. Chem. Centr., 1906, 2, 1264—1265.

The bixin was prepared by drying Orlean (annatto) on the water-bath, and extracting it for two days with cold chloroform, the first extract being rejected. From the solution, after evaporating the chloroform, a brittle reddish-brown mass was obtained, which yielded rhombic crystals (m.pt. 198° C., or 191·5° C. on slow heating) from a mixture of chloroform and alcohol, or from boiling glacial acetic acid. Bixin is slightly soluble in chloroform (0·34 grm. in 100 grms. at 25° C.), and almost insoluble in alcohol, ether, and glacial acetic acid; its best solvent is pyridine, and it is also soluble in quinoline and boiling nitrobenzene. It has the composition, $C_{27}H_{31}O_4(OCH_3)$, and on methylation with dimethyl sulphate, yields the dimethoxy-compound, $C_{27}H_{30}O_3(OCH_3)_2$. Monosodium and potassium salts of bixin were prepared. On reduction with zinc dust and glacial acetic acid, bixin yielded a substance forming orange-coloured rhombic crystals having a metallic lustre, m.pt. 200·5° C. (208°—210° C. on rapid heating), soluble in glacial acetic acid, and slightly soluble in chloroform, alcohol, and ether. This product contains 75·3—75·42 per cent. of carbon and 7·64 to 7·73 per cent. of hydrogen. On standing in the air, and more rapidly on heating at 100° C., the colour of the product fades, and an almost white substance is finally obtained containing 69·2 to 69·36 per cent. of carbon and 9·62 to 9·93 per cent. of hydrogen.—A. S.

Dyestuffs of the root of Datisca Cannabina; Studies on the ——. A. Korczynski and L. Marchlewski. Anz. Akad. Wiss. Krakau, 1906, 95—101. Chem. Centr., 1906, 2, 1265.

Schunck and Marchlewski (Annalen, 277, 261) isolated from the root of *Datisca Cannabina* a glucoside, which, on hydrolysis, yielded rhamnose and a compound, $C_{15}H_{12}O_6$, probably a dihydroxymethoxyxanthone. The authors have worked on fresh material from the Punjaub. By extracting the roots with boiling alcohol, evaporating the alcoholic solution, extracting the residue with boiling water, and cooling the solution, a glucoside was obtained as a yellowish-white precipitate, melting at 190° C. After recrystallising from a mixture of alcohol and ether, the product was hydrolysed, yielding a sugar and a compound, $C_{15}H_{10}O_6$, named *datiscetin*, which was purified by crystallisation from glacial acetic acid and dilute alcohol. Datiscetin contains four hydroxyl groups, yielding tetra-acetyl (m.pt. 138° C.) and tetrabenzoyl (m.pt. 190°—191° C.) derivatives. It is isomeric with luteolin and fisetin, and is probably a flavone- or flavonol-derivative; on heating with alkalis, it yields phenol and salicylic acid.—A. S.

Fluorescence and chemical constitution of organic substances; Relations between ——. L. Francesconi and G. Bargellini. Atti R. Accad. dei Lincei Roma, 1906, 15 [2], 184—191. Chem. Centr., 1906, 2, 1240—1242.

In examining substances for fluorescence, the authors place the solution of the substance in a small tube, the lower portion of which is disposed in a dark chamber. The tube is then placed at the focus of a converging lens about 12 cm. distant, which is exposed to the rays of the sun. On looking at the solution through the mouth of the tube, fluorescence is indicated by the appearance of a luminous sphere having a different colour to that of the solution. The authors have examined in this way about 500 different organic substances in various solvents, at different concentrations and temperatures, and have in many cases detected fluorescence where it was not visible to the naked eye—for example, in solutions of naphthalic anhydride and naphthalic-imide in alcohol, acetic acid, and acetone. Fluorescence was never observed with compounds of the methane series. It depends upon special modifications of the molecule, such as can only occur in aromatic nuclei, and is possibly due to a kind of tautomerism (compare Hewitt, this J., 1902, 127). All aromatic compounds are capable of exhibiting fluorescence, but the different nuclei possess the power in different degrees; in some it is latent, in others very weak, and in others strong. Where the fluorescence is latent, it can be made visible by introducing certain radicals into the compound. Benzoic acid, for example, is non-fluorescent, whilst *o*-amino-, methylamino-, and dimethylamino-benzoic acid are fluorescent. The authors classify substituting groups as "auxoflors" and "batoflors" according as they increase or diminish (or destroy) the power of exhibiting fluorescence. Amino and alkylamino groups are the most energetic auxoflors, to which class belong also the groups, OH, CN, COOH (and $COOC_2H_5$), and CH:CH. The groups, N:N, NO_2, Cl, Br, I, and COC_6H_5, especially the first, are batoflors, as also is the group, $COCH_3$, if it replaces a hydrogen of a hydroxyl or an amino group. The groups, SO_3H and CHO, have no decided action, but are not batoflors. (See also this J., 1902, 1327; 1903, 1311.)—A. S.

Catechu; Detection of adulteration in ——. D. Hooper. XXIII., page 1121.

Indigo crop of India. Chem. Trade J., Oct. 10, 1906. [T.R.]

The first General Memorandum on the indigo crop of the season 1906-07 has now been issued by the Commercial Intelligence Department of the Government of India. The provinces dealt with in this Memorandum contain 97·7 per cent. of the total area under indigo in British India, calculated on the averages of the five years ending 1904-05. The average acreage under the crop in that period was 755,900 acres, but in 1905-06 the total

acreage reported at the corresponding period was only 330,400, and the figures for 1906-07 are 329,800, the contraction in Bengal, the United Provinces, and the Panjab being almost counterbalanced by a large increase in Madras, attributed to seasonable rainfall. The condition of the crop is reported to be "fair to good" in Madras, and "average" in the Panjab, but there has been some damage done to the young plants by excessive rainfall in Bengal and the United Provinces.

ENGLISH PATENT.

Dyestuff of the anthracene series; Manufacture of a new ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 5890, March 10, 1906.

SEE Fr. Pat. 364,005 of 1906; this J., 1906, 923.—T. F. B.

UNITED STATES PATENTS.

Dye; Green anthraquinone ——. [*Anthracene dyestuffs*]. R. E. Schmidt, Elberfeld, Germany, Assignor to Farbenfabr. of Elberfeld Co., New York. Reissue No. 12,548, dated Oct 23, 1906, of U.S. Pat. 812,284, Feb 13, 1906.

DISULPHONIC acids of 1.4-diaryldiamino-8-hydroxyanthraquinones, probably containing one sulpho-group in the anthraquinone nucleus, and one in the aryl nucleus, are produced by sulphonating the monosulphonic acids (see Fr. Pat. 353,549 of 1905; this J., 1905, 1010). They dye wool yellowish-green shades. On heating with stannous chloride in hydrochloric acid solution, they are decomposed, a leuco compound of 1.4.8-trihydroxyanthraquinone-monosulphonic acid being formed.—T.F.B.

Hydro-azo derivatives; [Electrolytic] Manufacture of ——. O. Dieffenbach. U.S. Pat. 833,513, Oct. 16, 1906. XI*A*., page 1103.

Dyestuff; Blue azo ——. P. Julius, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 833,605, Oct. 16, 1906.

SEE Eng. Pat. 7287 of 1906; this J., 1906, 922.—T.F.B.

Indigo white; Alkali salt of ——, *and process of making same.* R. Wimmer, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U S. Pat. 833,654, Oct. 16, 1906.

SEE Eng. Pat. 23,122 of 1905; this J., 1906, 65.—T. F. B.

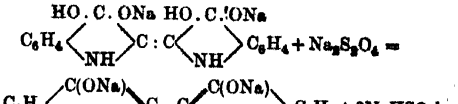
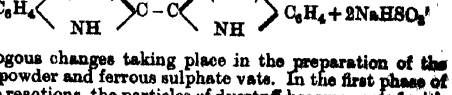
V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 1043.)



Dyeing processes. X. Solvents for, and mordanting power of metallic mordants. P. Heermann. Färber-Zeit., 1906, 17, 343—344.



BOILED-off silk was mordanted with solutions of tin, iron, and chromium mordants, in water, and mixtures of water and alcohol, and water and glycerol; all the solutions were made up to contain the same amounts of metal, and the mordanting was carried out under the same physical conditions in each case. The use of alcohol as a solvent, up to a mixture containing 50 per cent. of alcohol, was found to have very little effect on the quantity of mordant taken up by the fibre; in fact, with tin and iron mordants, the amount increased slightly. In the case of glycerol however, although small percentages exerted very little influence, the use of solutions containing 25 per cent. of glycerol or more caused a very considerable reduction in the amount of mordant absorbed by the silk: thus, a stannous chloride mordant dissolved in water gave a silk containing 8·7 per cent. of tin compounds calculated as stannic oxide, whilst the same weight of mordant dissolved in a mixture of 3 parts of glycerol to 5 parts of water (by volume) produced a fibre containing only 0·26 per cent. of tin compound calculated as stannic oxide.—T.F.B.

Indigo; Addition-compounds of alkalis and ——. A. Binz. Z. angew. Chem., 1906, 19, 1415—1418.

IN view of the facts (1) that neutral sodium indigotindisulphonate forms, as has been shown (this J., 1903, 901), addition-compounds with the hydroxides of sodium and calcium, (2) that indigo is electrolytically reducible by a zinc anode (loc. cit.), Binz and Walter conclude that in the setting of a hyposulphite (hydrosulphite) indigo vat the following reactions occur:—

(1) $C_{16}H_{10}N_2O_2 + 2NaOH = C_{16}H_{10}N_2O_2.2NaOH$

analogous changes taking place in the preparation of the zinc powder and ferrous sulphate vats. In the first phase of these reactions, the particles of dyestuff become coated with the sodium- or calcium hydroxide-indigo compounds which are formed. In the next phase, these compounds are deoxidised, the resulting products passing into solution as salts of Indigo White. The changes proceed in this manner until the whole of the indigo has been acted upon. The first reaction has been made the subject of a patent by the Badische Anilin- und Soda-Fabrik (Ger. Pat. 158,625 of 1903), who have described the formation of addition-compounds of alkali and alkaline-earth hydroxides and indigo, the existence of which had previously been pointed out by Binz and Walter. The preparation of these and similar compounds in the pure state offers considerable difficulties. In the present communication, the results of experiments made with this object are described.

1. *The addition of sodium hydroxide to Indigo.*—20 grms. of 99 per cent. indigo powder were shaken for 11 days with 840 c.c. of a filtered alcoholic sodium hydroxide solution prepared by dissolving 96 grms. of sodium hydroxide in 104 c.c. of water, and 640 c.c. of alcohol. Part of the mixture was filtered. The remainder of it was agitated during eight days longer. Part of this was also filtered. The residues, after pressing on porous plates, appeared as dark green, dry powders. On immersion in water or allowing to stand for some time exposed to the air, their colour changes to blue. Decomposition into indigo and alkali is effected still more slowly by alcohol. On analysis, the pressed masses were found to contain, per mol. of indigo, 1·90 and 2·0 mols. of sodium hydroxide. A determination of the amount of alkali mechanically or less powerfully retained by the indigo, was made by agitating the dyestuff with alcoholic potash, and immediately filtering, the pressed residue containing, per mol. of indigo, 0·89 of a mol. of sodium hydroxide. The differences, namely, 1·01 and 1·11, give the molecular proportions of alkali combined with 1 mol. proportion of indigo. The regenerated indigo, on testing, was found to be as pure as the original product. From the above results, it would appear that the alkali becomes strongly combined with half of the indigo molecule, the latter thus behaving, in relation to alkalis, the same as it does towards acids, with which it forms, *e.g.*, a stable and crystallisable monohydrochloride and monosulphate, but an unstable disulphate (this J., 1903, 20). The combination of indigo with alkali hydroxides may be brought about more rapidly by heating, than by agitating the aqueous or alcoholic mixtures. It begins to take place at about 40° C.; at 60° C. it is completed in a few minutes.

2. *The addition of sodium phenolate to Indigo.*—Mixtures of indigo and sodium phenolate were heated together in absolute alcohol, in one experiment, for 20 minutes at 77° C., in another, for an hour at 80° C. 0·73 and 0·60 mol. of sodium phenolate, per mol. of indigo, were respectively found to have become combined. Although the attraction of indigo for sodium phenolate is weaker than its attraction for alcoholic sodium hydroxide, the green coloration of the dyestuff produced on heating it with the former compound indicates that a reaction occurs, and that indigo, like quinone, has the power of forming an addition-compound with sodium phenolate.

3. *Influence of alcohol on the reduction of Indigo.*—The results of experiments made with aqueous and alcoholic mixtures of indigo, zinc dust, and sodium hydroxide, show that, under similar conditions, reduction of the dyestuff takes place about 30 times more rapidly in the alcoholic than in the aqueous mixtures. Alcoholic sodium hydroxide itself has no reducing action on indigo. At the temperature of boiling, a slight reaction occurs, with the formation, not of Indigo White, but of a decomposition-product which dissolves in alkalis with a green, and in acids and ether with a red colour. Alcohol aids the reducing action by its solvent action on the sodium-indigo. The latter in the aqueous mixtures, like the analogous calcium compound in the lime vats, continuously passes in minute quantities into solution, and in this condition becomes reduced. The fact that the reduction is retarded by the presence of a large excess of alkali, which hinders the solution of the sodium-indigo compound, is a further proof of this.

The essential difference between alkaline and acid reduction-processes, in the opinion of the author, is that, in the former, a molecular addition of alkali takes place, followed by a de-oxidation of the resulting product, whilst in the latter, hydrogen is directly added.—E. B.

Aniline black. C. Sünder. Z. Farben-Ind., 1906, 5, 400—401.

In order to obtain Prud'homme's Aniline Black, which does not turn green, the following conditions should be observed: The oxidation should not be too violent, or the colour may be dulled or even partially destroyed. Great care is necessary if an after treatment is resorted to; this also takes up much time, and is not a practical method. The black should not become appreciably darker on drying and stoving before being printed, and should be more neutral than a "Printing Black." If it is more difficult to obtain an ungreenable Prud'homme Black by the use of pure aniline than with the help of Oehler's salt (containing toluidine), it is, nevertheless, possible to approach this very nearly by careful choice of conditions. It is possible to oxidise so far, that the fabrics, after steaming, are not green but black. The shade is deepened by chroming or washing, but it is not greened by treatment with bisulphite and hydrochloric acid. Considering that a black is never greened so much by exposure to the air as by treatment with sulphurous acid, it is possible to say that a sufficiently nongreening Prud'homme black may be obtained with pure aniline, and it is very seldom necessary to use other bases.—J. C. C.

Silk; Determination of the Weighting of ——. J. Persoz. XXIII., page 1121.

English Patents.

Silk, artificial; Manufacture of ——. W. R. Lake, London. From R. Linkmeyer, Brussels. Eng. Pat. 3549, Feb. 13, 1906.

See Fr. Pat. 361,061 of 1905; this J., 1906, 692.—T.F.B.

Dyeing or treating with liquids, raw cotton, loose wool, or silk and like loose fibre or material; Machine for ——. F. Milan, Huddersfield. Eng. Pat. 21,311, Oct. 20, 1905.

The machine comprises a rotary cage having an inner shell or casing and an outer perforated shell, with radial, perforated, dividing walls or partitions. V-shaped perforated hollow ribs or prominences extend from the inner and outer shell, and from each partition, into the several chambers for the purpose of opening out the material to allow of the even distribution of the dye liquor. Buckets may also be fixed at or near the outer corner of each chamber, for the purpose of lifting liquor from the vat, and discharging it upon the fibres in the compartments, when the material is out of the liquor in the vat.—B. N.

Cleaning, dyeing, or otherwise treating wool, textile fabrics, and other like material; Apparatus for ——. M. Nicholas, London. Eng. Pat. 23,509, Nov. 15, 1905.

A cylinder is provided at each end with stuffing-boxes, through which pass two rods, the latter being connected inside the cylinder to two perforated plungers placed some distance apart. The material to be cleaned or dyed is introduced through water-tight man-holes in the cylinder, and is placed between the plungers. The outer ends of the rods are attached to an outside frame, which may be given a reciprocating motion by means of a suitable handle, and the dye-liquor is thus passed to and fro through the material.—B. N.

Bleaching or dyeing hanks, cops, and other fibrous materials; Apparatus for ——. J. Wilkinson, Colne, Lancaster. Eng. Pat. 12,117, May 24, 1906.

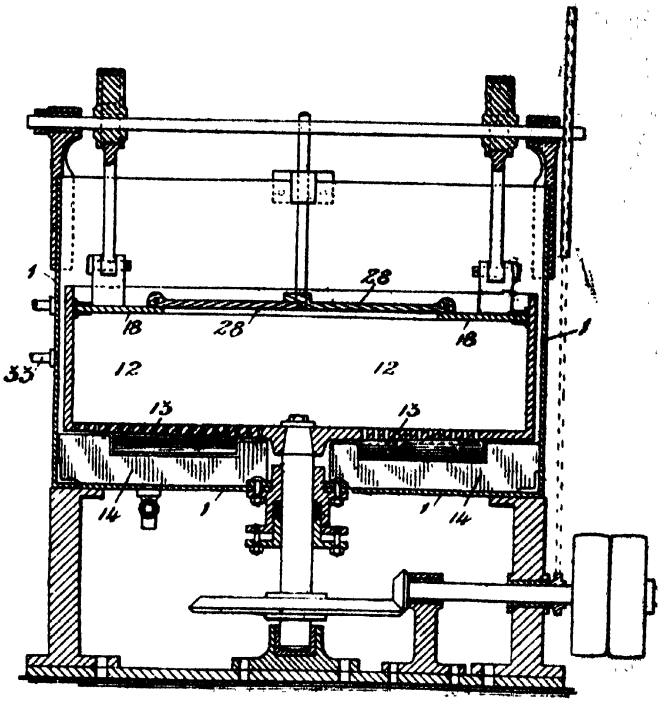
The bleaching or dyeing liquid contained in a receptacle separate and apart from the vat, in which the fabric is treated, is forced by means of a pump through the bottom of the vat, and after percolating through the material is returned to the receptacle. This operation is repeated until the desired shade or colour is obtained, the yarn being compressed by mechanical means and retained in this state during the entire process.—D. B.

Cleaning, dyeing or otherwise treating wool, hair, cotton, and other animal or vegetable fibrous or textile material; Apparatus for ——. T. A. S. Wood, London. Eng. Pat. 14,344, June 22, 1906.

Water is admitted into the fixed tank, 1, (see figure), having stationary blades, 14, across the bottom to prevent centrifugal movement. After heating to the desired temperature by introducing steam at 33, the doors, 28, are opened, and the fabric placed in the revolving cage, 12. The reciprocating action of the plunger, 18, in its downward movement, forces a great part of the liquid in the cage out through the perforations, 13, and opens out the

material, whilst during the upward movement a vacuum is created in the cage, thus lifting the material, and ensuring the contact of the liquid with every portion of the fabric.—D. B.

Formaldehyde hydrosulphites and sulphoxylates; Manufacture of ——. G. B. Ellis, London. From Chem. Fabr. von Heyden Akt.-Ges., Radeboul, Saxony. Eng. Pat. 13,788, June 15, 1906.



See Fr. Pat. 366,867 of 1906; following these.—T.F.B.

Silk; Treatment of —— with thiourea, its salts, or its substitution derivatives. H. H. Lake, London. From Soc. Anon. Co-operativa per la Stagionatura e. l'Assaggio delle Sete ed Affini, Milan, Italy. Eng. Pat. 25,752, Dec. 11, 1905.

See Fr. Pat. 358,033 of 1905; this J., 1906, 262.—T.F.B.

Drying cylinders [for fabrics]; Steam ——. W., J. G., and J. A. Buck, Manchester. Eng. Pat. 21,594, Oct. 24, 1905.

To facilitate repairs in connection with steam-drying cylinders, and provide means for automatically discharging condensed water, an iron flange having T-shaped apertures is fitted within each end of the cylinder. T-headed screw bolts are placed in the apertures, and the cylinder doors are secured by passing the bolts through holes formed at corresponding distances apart. Each half of the cylinder is provided with a pair of double condensing water-lifting buckets, semi-circular in shape, and tapering longitudinally, and arranged so that the water scooped up by the bucket nearest the steam inlet end is tipped into the adjacent bucket, which delivers it into one of the buckets at the other end of the cylinder, and this in turn discharges it into its adjacent bucket, which is provided with means for removing the condensed water.—D. B.

Oil from cleaning wool, cotton waste, and the like; Centrifugal machines for removing ——. E. Fischer, P. Arnold, and E. Illig, Chemnitz, Germany. Eng. Pat. 10,517, May 4, 1906.

See Fr. Pat. 365,910 of 1906; following these.—T.F.B.

United States Patent.

Silk; Method of winding —— to facilitate treatment thereof [with liquids]. L. Détré, Rheims, France. U.S. Pat. 833,374, Oct. 16, 1906.

See Fr. Pat. 348,368 of 1904; this J., 1905, 495.—T.F.B

French Patents.

Artificial silk and collodion products; Manufacture of ——. Fabr. de Soie Artificielle de Tubize. Fr. Pat. 361,690, Aug. 11, 1905.

By adding a sulphonated hydroxy-acid or a sulphonated fatty acid in acid, neutral, or alkaline solution to the materials used in the manufacture of nitrocellulose or collodion, it is found that the nitrated product is much more soluble in the usual solvents than the ordinary product. The acids mentioned form a stable compound with the nitro-cotton, so that the artificial silk produced does not consist only of nitrocellulose, but of this compound, and as a result, the specific gravity of the product is nearer to that of real silk. The sulpho acids can be added to the cotton before or after nitration, or else to the solvent liquids.—A. B. S.

Artificial fibres; Washing and drying of ——. E. W. Friedrich. Fr. Pat. 366,793, June 2, 1906. Under Int. Conv., June 15, 1905.

The bobbins of artificial silk fibres, after being removed from the spinning machine, are placed in a horizontal position in washing baths, the liquid in which reaches up to the axis of the bobbin. The bobbins are slowly rotated on their axes in the liquid. The action of centrifugal force is avoided by the slowness of the rotation, so that the liquid is absorbed by the fibre, and penetrates to the lower layers. To dry the bobbins, they are placed in a drying chamber, and a similar slow rotary motion is given to them.—A. B. S.

Sheet or film; Thin ——, *and process for making same* W. A. Ker. Fr. Pat. 366,891, June 5, 1906.

See U.S. Pat. 826,781 of 1906; this J., 1906, 1040.—T.F.B.

Cleaning wool, &c.; Centrifugal turbine for degreasing —— *with the aid of steam.* E. Fischer and Co. Fr. Pat. 365,910, May 4, 1906.

The grease-charged materials to be treated are packed in baskets or perforated boxes of a special shape, which fit into the perforated, rotary drum of a centrifugal machine into which they are placed, in such a manner that spaces are left between and around them. Steam is passed into the chamber in which the drum is inclosed. This penetrates into the spaces surrounding the baskets, and thence into the materials, which it heats, thus melting the grease and facilitating its removal from the materials by the centrifugal action of the apparatus.—E. B.

Antimony compounds, obtained by reaction with lactates of alkalis or alkaline-earths; Process and materials for mordanting with tannic acid and ——. A. Eberdt Söhne. Fr. Pat. 365,722, April 28, 1906.

Antimony compounds which, like "Antimonine" (this J., 1897, 737), are advantageously employed as fixing agents for tannic acid, in the mordanting of textile materials, are obtained by mixing together, in solution or in the dry state, lactates of alkalis or alkaline-earths and antimony

salts, such as tartar emetic, "de Haeus's" (de Haen's) "antimony salt," $SbF_3.(NH_4)_2SO_4$, Köpp's salt, $SbF_3.NaF$, von Raad's double fluoride salt, &c., in the proportions required for the replacement by lactic acid of the acid combined with the antimony, *e.g.*, $2SbF_3.NaF$ and $3Ca(C_3H_5O_3)_2$, and "$2KSb(C_4H_4O_6)\frac{1}{2}H_2O$" and $Ca(C_3H_5O_3)_2$. When the salts are mixed in solution, a clear solution is obtained with tartar emetic and calcium lactate; the fluoride double salts give with the latter salt a finely divided precipitate of calcium fluoride, which does not, however, interfere with the fixing of the tannic acid. The mixtures, *e.g.*, powders, of the respective compounds in the dry state, have the advantage, compared with "Antimonine," of being obtainable in a colourless, dry, easily soluble state, containing definite amounts of antimony oxide, whilst the latter preparation, in which at least 6 mols. of lactic acid are combined with "1 mol." (2Sb) of antimony, is sold as a strongly smelling, cheese-like mass, in which the content of antimony oxide (about 15 per cent.) varies according to the degree of humidity of the pasty mass. According to the salts employed, the (calcium lactate) mixtures contain the following percentages of antimony trioxide: De Haen's salt, 18 per cent.; Köpp's salt, 21 per cent.; von Raad's salt, 25 per cent; the tartar emetic mixture, 30 per cent.—E. B.

Cotton, ramie, and other textile fibres in the loose or partially spun state; Apparatus for bleaching and dyeing ——. E. Steiner. Fr. Pat. 365,793, May 1, 1906.

COTTON, ramie, &c., in the loose state or in the form of sliver or slubbing, are placed in a cylindrical vessel, provided with liquor-circulating pipes, a steam-injector, and a steam-coil placed below a false bottom. Loose fibres are directly pressed into the vessel, and covered with a perforated plate. Slubbing is put into the apparatus in compact masses, coiled round short rods, and compressed between cross-shaped end-pieces. The fibres are then bleached or dyed by circulating, by means of a centrifugal pump, the necessary liquors through them. —E. B.

Fur; Apparatus for the "secrétage" and dyeing of ——. T. Pernin. Fr. Pat. 367,163, June 14, 1906.

THE machine consists essentially of a large cylinder, around which a number of revolving brushes and pressure rollers are fitted which are in contact with the central cylinder. The skin to be treated is placed on a sloping table, and is seized by a revolving brush which passes it along the face of the large cylinder until it comes under a small spring roller, which the thickness of the skin pushes away from the central cylinder. This spring-roller is connected by means of a series of levers with the driving arrangement of the first brushing wheel, and its movement causes the direction of rotation of the latter to be reversed. Thus, as soon as the skin is seized by the second roller, the brushing of the fur takes place in the opposite direction. One or more other brushes may be fitted around the large cylinder. The brushes dip into vessels containing the liquids which it is desired to apply to the skins, these vessels being furnished with a constant level arrangement. —A. B. S.

Printing with sulphide dyestuffs; Process for ——. L. Cassella und Co. Fr. Pat. 361,742, Sept. 2, 1905.

SEE Eng. Pat. 1300, of 1906; this J., 1906, 586.—T. F. B.

Ketone and aldehyde-hyposulphites (hydrosulphites) and sulphoxylates; Preparation of ——. Chem. Fabr. von Heyden A.-G. Fr. Pat. 366,867, June 5, 1906.

KETONE-HYPOSULPHITES (hydrosulphites) of the type, $R_2S_2O_4.2(CH_3)_2CO$, can be obtained by treating free or combined sulphurous acid with zinc powder, or with zinc powder and an acid, in the presence of ketones. The proportions to be employed are about one atom of zinc for every 2 mols. of sulphurous acid taking part in the reaction, and 2 mols. or an excess of ketone. Example: 120 kilos. of sulphurous acid are introduced with constant stirring into a mixture of 120 kilos. of acetone, 70 kilos. of zinc powder, and 200 litres of water, the temperature being kept at 20°—30° C. The zinc acetone-hyposulphite obtained can be converted into the sodium salt by treatment with sodium carbonate in the usual way. The ketone-sulphoxylates are obtained by complete reduction of sulphurous acid in the presence of acetone by means of zinc or of zinc and acid. This reduction is carried out warm. One atom of zinc is taken for 1 mol. of sulphurous acid and one of acetone. The reaction probably proceeds as follows:—

$$(CH_3)_2CO + SO_2 + Zn + H_2O = (CH_3)_2C.(OH)(SO_2)ZnOH.$$

The acetone hyposulphite may be formed first, and then further reduced by zinc dust to the sulphoxylate, thus:—

$$ZnS_2O_4.2(CH_3)_2CO + Zn + 2H_2O = 2(CH_3)_2.C(OH)(ZnOH)SO_2.$$

The acetone-sulphoxylates are employed as reducing agents for Indigo, &c.—A. B. S.

Waterproofing of fibres, fabrics, paper, &c. E. Meulders and C. Bourlet. Fr. Pat. 366,951, March 17, 1906.

THE material is padded with a solution of aluminium acetate, and after drying is soaked for two days in a dilute solution of tannin. Another method is to soak in a solution prepared by mixing a solution of aluminium acetate with a very dilute solution of tannin. The material is exposed to the air for some days, whereby, it is stated, a "sub-tannate" of aluminium is produced.—A. B. S.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(*Continued from page* 982.)

Dyed materials [*Wood*]; *Penetration of the bleaching action of light on* ——. W. H. Schramm and A. Jungl. Färber-Zeit., 1906, 17, 333—342.

THE authors have investigated the action of light on various dyed materials, especially on wood of various kinds. After exposure to light a section was cut at right angles to the surface, and the thickness of the bleached layer was measured with a micrometer eye-piece. It was found that for the dyestuffs and woods employed, the thickness of the bleached or altered layer after six weeks' exposure to the sun in July and August averaged 0·033 mm. The effect of longer exposure showed that the bleached layer had little moderating action on the effect of the light on the lower dyed layers. The placing of thin coloured layers of wood or other semi-transparent material on the surface of the dyed wood had a very large effect on the bleaching of the latter. The authors conclude that for wood dyeing, in cases where the wood has to stand no mechanical wear, a dyed layer, 0·03—0·06 mm., is enough, and this is obtainable by simply brushing the dye-liquor over the surface of the wood.—A. B. S.

ENGLISH PATENT.

Skins, waste of skins, and hair; The dyeing and secreting of ——. C. and E. Pichard, Paris. Eng. Pat. 9629, April 24, 1906. Under Int. Conv., June 9, 1905.

SEE Fr. Pat. 355,121 of 1905; this J., 1905, 1227.—T. F. B.

FRENCH PATENT.

Wood dyeing; Apparatus for ——. M. Schmidt. Fr. Pat. 367,059, June 11, 1906.

THE wood to be treated is supported in a horizontal position by means of metallic supports placed at each end. The wood is gripped between two vertical pieces attached to the metallic supports and faced with a layer of caoutchouc to make good contact with the surface of the wood. One of the supports can be moved horizontally by means of a screw worked by a capstan wheel in order to fit various lengths of wood. A tube passes through each support, emerging at the centre of the rubber surface, the other ends being connected by flexible pipes with the vessels containing the dyeing or other liquids. The liquid is contained in a hermetically-sealed vessel, from which it is forced by means of compressed air into the tube passing through one of the supports

of the wood. The liquid passes along the wood in a horizontal direction, and the excess emerges through the pipe at the other end. If necessary, the direction of flow can be reversed.—A. B. S.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 1045.)

Sulphuric acid; Contact process for ——. L. Wöhler, A. Foss, and W. Plüddemann. Ber., 1906, **39**, 3538—3549.

The authors have used as contact substances the metals, platinum, palladium, and iridium, and their oxides, and have measured the speed of the reaction in each case. In every case the oxide was inferior as a catalyst to the metal which it contained, and the intensity of its action increased just in proportion as it decomposed into metal and oxygen. Moreover, whilst the stability of the oxides increases in the order: platinum, palladium, iridium, the temperature of maximum catalytic activity rises in the order, platinum, iridium, palladium. The working of the contact-process, therefore, is clearly not dependent on the formation and decomposition of either of the oxides, PtO or PtO_2. The authors have already obtained indications that the decomposition of hydrogen peroxide by platinum is due to the presence and action of an endothermic platinum peroxide, and they suggest the possibility of this peroxide being the active substance in the contact process of sulphuric acid manufacture.

—J. T. D.

Hydrogen sulphide; Oxides of ——. E. Fromm and J. de S. Palma. Ber., 1906, **39**, 3317—3326.

As from sulphurous acid, H_2SO_3, are derived the sulphonic acids $R.SO_3H$, so from hyposulphurous acid, H_2SO_2 (Bernthsen's sulphoxylic acid), are derived the sulphinic acids, $R.SO_2H$, and the sulphones, $R.SO_2.R$; whilst the unknown H_2SO may be looked on as the parent of the sulphoxides R.SO.R. The authors have found that benzyl chloride in alkaline solution reacts quantitatively with sodium sulphite to form sodium benzylsulphonate, and they have applied this reaction to the other oxides of hydrogen sulphide. Sodium hyposulphite, $Na_2S_2O_4$, thus treated, yields sodium benzylsulphonate and sodium benzylsulphinate, the latter of which is converted by excess of benzyl chloride into benzylsulphone; thus evidence is afforded in favour of Binz's formula for sodium hyposulphite, O:(SNa).O.(NaS)O$_2$. The same reaction has enabled the authors to prove that when sulphuryl chloride and zinc dust react, there is formed not zinc hyposulphite, $2SO_2Cl_2 + 3Zn = 2ZnCl_2 + ZnS_2O_4$, but zinc sulphoxylate, $SO_2Cl_2 + 2Zn = ZnCl_2 + ZnSO_2$, for the reaction of benzyl chloride and alkali on the product yields benzylsulphone unmixed with any sodium benzylsulphonate. The reaction of benzyl chloride and alkali on sodium hyposulphite is very sharp, and may possibly be used for the quantitative determination of hyposulphites. Attempts to form the substance, H_2SO or HS:OH (which may be regarded as intermediate between hydrogen peroxide and hydrogen persulphide), and to prove its formation by the benzyl chloride and alkali reaction, were all fruitless.—J. T. D.

Sodium hypochlorite; Depreciation of electrolytically-produced solutions of ——. W. P. Digby. Paper read before Faraday Soc., Nov. 13, 1906. [Advance proof.]

Details of experiments are given, showing that certain conditions of storage injuriously affect the stability of hypochlorite solutions; more particularly contact, in such cases, with dissimilar metals, resulting in galvanic action, is liable to result in decomposition. The relative order of values of different metals is given as causing such depreciation, but these figures are stated to be absolute only as regards the product of the factory dealt with. The author has devised a "galvanic couple test," which in a given time, for any solution, will indicate what may be called its "stability coefficient." Detailed tests are now being made with various hypochlorite solutions both "chemical" and "electrolytic," with a view to simplify the methods, and a further paper is promised.

—B. N.

Ammonium salts; Hydrolysis of ——. A. Naumann and A. Rücker. J. prakt. Chem., 1906, **74**, 249—275.

A method has been devised by the authors by means of which the hydrolysis of ammonium salts was calculated from the quantity of ammonia obtained by distillation. By its use, determinations of the extent of hydrolytic dissociation have been made at the boiling point of aqueous solutions of the following compounds:—Ammonium chloride, bromide, and thiocyanate, ammonium sodium sulphate, $NH_4NaSO_4.3H_2O$; ammonium sulphate, chromate, bichromate, and oxalate, $(NH_4COO)_2.H_2O$; Mohr's salt, $(NH_4)_2SO_4.FeSO_4.6H_2O$; iron ammonium alum, $(NH_4)_2SO_4.Fe(SO_4)_3.24H_2O$; microcosmic salt $(NH_4)NaHPO_4.4H_2O$; ammonium phosphate, $(NH_4)H_2PO_4$; diammonium phosphate, $(NH_4)_2HPO_4$; triammonium phosphate, $(NH_4)_3PO_4$; and ammonium molybdate, $(NH_4)_6Mo_7O_{24}.4H_2O$. The distillation of pure solutions of ammonia gave results, which proved the absence of proportionality between the concentration of the solution and the partial pressure of ammonia. The latter was found to decrease considerably as the concentration diminishes, a circumstance which harmonises with the conclusions previously drawn concerning the composition of aqueous solutions of ammonia. The hydrolysis of salts increases with decreasing salt concentration, although not in accordance with Ostwald's equation governing the law of mass action: $\frac{x^2}{n-x} = K$, which can be made to apply only to ammonium chloride and bromide, *i.e.*, salts containing strong monobasic acids. It is stated that titrations of ammonia, especially in dilute solution, should be made with hydrochloric acid. Sulphuric acid, owing to the dissociation of ammonium sulphate, tends to exhibit an acid reaction at too early a stage. (See also Watson Smith, this J., 1896, 4.)—D. B.

Potassium-lead chlorides. R. Lorenz and W. Ruckstuhl. Z. anorg. Chem., 1906, **51**, 71—80.

The authors determined the cooling curve of fused mixtures of lead chloride and potassium chloride, the mixtures being heated in a tube of hard glass in which a thermo-couple was fixed. Evidence was obtained of the formation of three double chlorides, and the existence of these compounds was confirmed by crystallographic examination of the solidified melts. The compound, $2PbCl_2.KCl$, was obtained as a nearly transparent, glassy mass, on the surface of which a distinct crystalline structure could be observed. The compound, $PbCl_2.2KCl$, was obtained in a fairly pure condition by repeated very slow cooling of the melts, the solid being powdered each time before fusing. It formed a mass of tightly-packed, well-defined crystals, which had a tendency to appear in twisted prismatic forms. The crystals exhibited a distinct similarity to rhombic cerussite ($PbCO_3$). The compound, $PbCl_2.4KCl$, was obtained by slowly cooling a melt of the requisite composition, as a reddish-white mass of granular structure. The compounds, $PbCl_2.2KCl$ and $PbCl_2.4KCl$, decompose when heated above 440° C. and 490° C. respectively.—A. S.

Steam; Dissociation of ——. H. v. Wartenberg. Z. physik. Chem., 1906, **56**, 513—533.

Two methods were used, and it is shown that at about 1100° C. the reaction is trimolecular. A porcelain bulb of 13 c.c. capacity, with two long capillary arms, was heated electrically, and the temperature measured by a thermo-couple placed outside the bulb to avoid catalytic action. A current of steam was passed through the bulb at different rates, and the amounts of free hydrogen and oxygen formed were measured in a 3 c.c. eudiometer graduated to 0·02 c.c. At 1130° the reaction was slow, and equilibrium was not reached. Experiments were also made with steam mixed with known amounts of hydr-

hydrogen gas obtained electrolytically. Curves drawn with the observed dissociations as ordinates and the reciprocals of the rates of flow of steam as abscissæ enable the degree of dissociation for equilibrium at this temperature to be determined by extrapolation. The value found is 0·007 per cent. The value calculated for a trimolecular reaction is 0·0078 per cent. Similar experiments with carbon dioxide showed that at 1200°—1300° the reaction is probably trimolecular in this case also. The second method used, suitable for higher temperatures, consisted in measuring the partial pressure of the hydrogen which diffused into a vacuous iridium bulb placed in a current of steam passing through an iridium tube heated to nearly 2000°. The temperature was measured by the optical method, and is probably correct within 10° or 15°. The degree of dissociation was found to be 1·18 per cent. at 1882°, and 1·77 per cent. at 1984°.

—A. T. L.

Steam; Dissociation of ——. W. Nernst and H. v. Wartenberg. Z. physik. Chem., 1906, **56**, 534—547.

THE experiments were made with apparatus similar to that described in the preceding abstract (first method), but the temperature was measured by means of a thermocouple in a sealed, thin-walled porcelain tube placed inside the porcelain bulb. The quantity of electrolytic oxyhydrogen gas added to the steam was determined from measurements of the current used; the water used was slightly alkaline, to avoid the formation of hydrogen peroxide. Experiments were carried out at three temperatures; in each case, curves were plotted having as ordinates, the oxyhydrogen gas found, and as abscissæ, the oxyhydrogen gas added, and were interpolated to find the equilibrium value at which the ordinates and abscissæ of the curve are equal. The final values are:—

Temperatures.	Degree of dissociation.
1124° C.	0·0078 per cent.
1207°	0·0189 per cent.
1288°	about 0·034 per cent.

A formula is deduced from thermal data, from which the degree of dissociation at any temperature can be calculated, and the agreement with the observed values is practically complete. The formula is used to calculate the degree of dissociation of steam at several pressures and temperatures.

Degree of dissociation (x) of steam at atmospheric pressure.

Temp. absolute.	x per cent.	Log. x.	Temp. absolute.	x per cent.	Log. x.
1000	$3·00 \times 10^{-5}$	−4·523	1800	0·199	− 0·702
1100	$1·82 \times 10^{-4}$	−3·740	1900	0·354	− 0·451
1200	$8·13 \times 10^{-4}$	−3·090	2000	0·588	− 0·231
1300	$2·91 \times 10^{-3}$	−2·536	2100	0·935	− 0·029
1400	$8·61 \times 10^{-3}$	−2·065	2200	1·42	+ 0·152
1500	$2·21 \times 10^{-2}$	−1·655	2300	2·08	+ 0·318
1600	$5·07 \times 10^{-2}$	−1·295	2400	2·92	+ 0·465
1700	0·105	−0·980	2500	3·98	+ 0·599

Values at intermediate temperatures may be found by taking proportional differences of log. x.

Degree of dissociation of steam at different pressures.

Temp. absolute.	P=10 atm.	P=1 atm.	P=0·1 atm.	P=0·01 atm.
1000	$1·39 \times 10^{-5}$	$3·00 \times 10^{-5}$	$6·46 \times 10^{-5}$	$1·39 \times 10^{-4}$
1500	$1·03 \times 10^{-2}$	$2·21 \times 10^{-2}$	$4·78 \times 10^{-2}$	0·103
2000	0·272	0·588	1·26	2·70
2500	1·93	3·98	8·16	16·6

The results are used to show that the electromotive force corresponding to the reaction is

$$1·232 - 0·00085(t - 17) \text{ volts},$$

where t is the temperature (°C.), a value considerably higher than that obtained by direct measurements.

—A. T. L.

Carbon dioxide; Dissociation of ——. W. Nernst and H. v. Wartenberg. Z. physik. Chem., 1906, **56**, 548—557.

THE method and apparatus used were similar to those described in the preceding abstract. The carbon dioxide could be mixed with its dissociation products by sparking. It was found necessary to dry the gas very thoroughly, as water exercises a powerful catalytic influence on the reaction. The degree of dissociation at 1205° C. was found to be 0·029 per cent. The degree of dissociation at 1300° C. is deduced indirectly from the equilibrium $CO + H_2O \rightleftharpoons CO_2 + H_2$, and the results given in the preceding abstract. The value obtained is 0·00414 per cent. Thermal data give a formula, connecting the degree of dissociation with the temperature, which agrees with these values. The following values are calculated from this formula:—

Degree of dissociation (x) of carbon dioxide at atmospheric pressure.

Temp. absolute.	x per cent.	Log. x.	Temp. absolute.	x per cent.	Log. x.
1000	$1·58 \times 10^{-5}$	− 4·71	1800	0·507	− 0·295
1100	$2·00 \times 10^{-4}$	− 3·801	1900	0·978	− 0·010
1200	$8·94 \times 10^{-4}$	− 3·048	2000	1·77	+ 0·248
1300	$3·89 \times 10^{-3}$	− 3·410	2100	3·03	+ 0·481
1400	$1·38 \times 10^{-2}$	− 1·861	2200	4·88	+ 0·688
1500	$4·06 \times 10^{-2}$	− 1·392	2300	7·55	+ 0·878
1600	0·104	− 0·981	2400	11·3	+ 1·054
1700	0·242	− 0·617	2500	15·8	+ 1·200

Degree of dissociation of carbon dioxide at different pressures.

Temp. absolute.	P=10 atm.	P=1 atm.	P=0·1 atm.	P=0·01 atm.
1000	$7·31 \times 10^{-6}$	$1·58 \times 10^{-5}$	$3·40 \times 10^{-5}$	$7·31 \times 10^{-5}$
1500	$1·88 \times 10^{-2}$	$4·06 \times 10^{-2}$	$8·72 \times 10^{-2}$	0·188
2000	0·818	1·77	3·73	7·88
2500	7·08	15·8	30·7	53·0

—A. T. L.

Water vapour and carbon dioxide; Dissociation of —— at high temperatures. I. Langmuir. J. Amer. Chem. Soc., 1906, **28**, 1357—1379.

THE experiments described by the author were made with the view to test a suggestion of Nernst, that around a glowing metallic wire, in a gas capable of dissociating, there would probably be only very slight re-combination of the dissociation products during the short time required for these to diffuse from the surface of the wire into the comparatively cold layers only a short distance from the wire; and, also, that if the wire exerted a sufficiently strong catalytic action, there would be equilibrium at the surface of the wire, and hence the cold gas some distance from the wire would have the same composition as would have been the case had the whole gas been uniformly heated to the temperature of the wire. Experiments on the dissociation of steam and carbon dioxide showed that, by this method, equilibrium around the wire is reached with great rapidity, and that the degree of dissociation is, within wide limits, independent of the velocity of the current of gas passed over the glowing wire. The temperature of the wire was ascertained by means of the change in its electrical resistance. The results obtained with steam and carbon dioxide at temperatures between 1000° and 3000° absolute were 9·5 and 7 per cent. respectively lower than those obtained by Nernst by another method (see preceding abstracts). The method has many

advantages, and would probably be especially useful in measuring dissociation at high pressures. In the course of the experiments, it was found that platinum and platinum-rhodium (10 per cent. of rhodium) wires do not disintegrate perceptibly in steam or carbon dioxide up to 1300° C., but at 1400° C. platinum-rhodium begins to disintegrate in steam.—A. S.

Deacon [chlorine] process; Equilibrium in the ——. G. N. Lewis. J. Amer. Chem. Soc., 1906, **28**, 1380—1395.

Previous investigations of the Deacon process have been conducted under actual working conditions, in which the gases are passed over the catalyser too rapidly for the establishment of equilibrium (see Lunge and Marmier, Z. angew. Chem., 1897, 105). In the author's experiments the catalyser was prepared by boiling pumice stone, in pieces about the size of a pea, with hydrochloric acid, saturating them with a 10 per cent. solution of cupric chloride, and drying in a current of dry hydrochloric acid gas at 250° C., until evolution of water vapour ceased. On passing the mixture of oxygen and hydrochloric acid gas, no concordant results could be obtained until after several days, owing to slow changes in the catalyser. The time required to attain a state of equilibrium in the gaseous mixture was greater the lower the temperature, and the smaller the percentage of oxygen present. A summary of the results obtained is given in the following table, wherein x represents the ratio of free chlorine to total chlorine in the final gaseous mixture, and K is the equilibrium constant of the reaction:—

Temp. ° C.	Average pressure, atmospheres.	Mols. of oxygen per 100 mols. of hydrochloric acid		x.	K.
		In original gas.	In final gas.		
352	1·00	92·7	544·0	0·869	4·15
352	0·93	29·7	49·5	0·808	3·95
386	0·98	327·0	1970·0	0·845	2·04
386	0·96	48·8	146·0	0·804	3·01
419	1·08	327·0	1700·0	0·820	2·40

It is shown that the equilibrium constant, K, at any temperature can be calculated by the formula: $\log K = \frac{1509}{T} - 1{\cdot}811$, where T is the absolute temperature. The yield of chlorine from a given mixture is greater the lower the temperature.

From the results obtained in this investigation, together with some results of Dolazalek (Z. physik. Chem., 1898, **26**, 334), the E.M.F. of the hydrogen-oxygen cell at 25° C. is calculated to be 1·207 volts, a result agreeing well with that previously obtained by the author (J. Amer. Chem. Soc., 1906, **28**, 158) in a different manner, *viz.*, 1·217±0·010 volts, but about one-tenth of a volt higher than the value accepted at present.—A. S.

Oxygen and nitrogen; Mixtures of liquid ——. A. Stock and C. Nielsen. Ber., 1906, **39**, 3393—3397.

As the result of a series of very careful experiments, the authors show that the boiling point even of dilute solutions of nitrogen in liquid oxygen is lower than that of pure oxygen, and accordingly that liquid oxygen can be completely freed from nitrogen by boiling. On mixing equimolecular weights of liquid oxygen and nitrogen at −197° C., a rise in temperature of about ½° and a diminution in volume of about ½ per cent. are observed; these small changes are ascribed to association phenomena, and are of the same order as those observed on mixing indifferent substances, such as hydrocarbons.—E. Italy; Chemical industry of ——. Oil and Colour Trade J., Oct. 27, 1906. [T.R.]

Chemical industries in Italy have been handicapped by the operations of fiscal legislation and commercial treaties in addition to the scarcity of ores, the want of coal, dearness of transport, and difficulties in river communication. Several large factories have been erected of late for the manufacture of beetroot sugar, calcium carbide, the electrolytic production of caustic soda, and of hypochlorites. The factories for making chemical manures and sulphuric acid have developed considerably. The production and value of chemicals, &c., during the year 1901 was as follows:—Sulphuric acid, 2,778,440 quintals, 9,468,070 lire; calcium carbide, 273,149, 5,872,980; superphosphates, 4,590,190, 87,391,730; lead carbonate, 4,988, 2,226,300; carbon bisulphide, 25,230, 725,415; magnesium sulphate, 51,540, 360,880; sodium sulphate, 250,000, 825,000. (1 quintal = 2 cwts., nearly; 25 lire = £1 sterling.) The total value of the yearly output of the Italian chemical works is considerably over 100,000,000 lire. A revival in the trade is also noticeable, which is full of promise; but it is thought that a more general and at the same time more rational utilisation of water power, coupled with the progress that electro-chemistry is making, would render it possible for many industries to be started in Italy which have hitherto only existed in coal-producing countries. With the object of protecting and fostering chemical industry, an association under the style of "Associazione per l'incremento e per la tutela dell' Industria Chimica Italiana" was formed in Italy some months ago, with headquarters at Milan, by an influential body of chemists, and supported since by others.

English Patents.

Common salt; Manufacture of —— by evaporation of brine. G. R. Ray, Manistee, U.S.A. Eng. Pat. 5427, March 6, 1906.

The main through which the brine is conveyed to the "leg" of an evaporating pan is also connected to the upper portion of the pan by means of a pipe which communicates with the pan above the brine-circulating tubes, preferably at a point between the top of the tubes and the normal surface of the brine when the apparatus is in use. The larger portion of the brine is supplied to this upper inlet; the lower inlet may be disposed on the side of the "leg" nearest the elevator to prevent clogging. A pipe is also provided, leading from the brine main to a reservoir above, from which another pipe leads to the salt elevator. A portion of the brine is pumped to this reservoir, which is provided with a ball valve, and thence flows in regulated quantity to the pan by way of the elevator, thereby washing the salt as it is elevated. This "salt wash feed" may consist of the brine which strains from the salt. Thus, in triple effect apparatus, the elevators of the first and second effects are fed from a single reservoir, whilst the elevator of the third effect pan is fed by brine drained through the perforated floors of the salt bins.—A. G. L.

Ferrocyanides; Manufacture of —— from gas-purifying masses or other ferrocyaniferous masses. T. Bellowitsch, Vienna. Eng. Pat. 8362, April 6, 1906.

Masses of the material used in purifying gases, after having been washed with water, are heated to about 90° C. in an apparatus provided with stirring and loosening means; water is added, and slowly, by small portions, an intimate mixture of 6 to 14 per cent. of lime, with 4 to 10 per cent. of manganese peroxide, or its equivalent of Weldon mud, of the weight of the mass treated, air or oxygen being admitted throughout the process. The product is drained and lixiviated, and the lixivium is worked up by known methods for the production of alkali ferrocyanides. (Reference is made to Eng. Pat. 3551, of 1876; and to U.S. Pat. 649,048 of 1900.)—E. S.

Oxides of nitrogen; Method of producing —— by means of explosions such as in explosion engines. F. Häusser, Kaiserslautern, Germany. Eng. Pat. 12,401, May 28, 1906. Under Int. Conv., May 31, 1905.

See Fr. Pat. 361,522 of 1905; this J., 1906, 885.—T. F. B.

UNITED STATES PATENT.

Sulphur; Extraction of —— from gas-purifying materials. J. J. M. Bécigneul, Nantes, France. U.S. Pat. 833,573, Oct. 16, 1906.

See Fr. Pat. 345,071 of 1904; this J., 1904, 1216.—T. F. B.

FRENCH PATENTS.

Aluminium; Manufacture of nitrogenised compounds of —— [for production of ammonia]. O. Serpek. Fr. Pat. 367,124, June 13, 1906. Under Int. Conv., June 20, 1905.

THE object of the invention is to produce nitrogenised compounds of aluminium, which, on contact with water, preferably under pressure in an autoclave, and at a higher temperature than 100° C., give off ammonia. For this purpose, aluminium carbide, alone, or mixed with carbon, alumina, or aluminium chloride, or any mixture of these; or with metals, such as copper, aluminium, or iron, or their alloys, all in powder, is subjected at a high temperature to the action of nitrogen or air, to which may be added hydrochloric acid gas or sulphuric anhydride vapour. Instead of starting the process with a preformed aluminium carbide, a mixture of alumina with carbon may be heated, preferably by resistance in an electric furnace, in presence of nitrogen, with addition of one or more of the substances contributory to the formation of the required product already named.—E. S.

Sodium monosilicate; Manufacture of crystallised ——. W. N. Bacon. Fr. Pat. 366,895, June 5, 1906. Under Int. Conv., Nov. 23, 1905.

See Eng. Pat. 24,226 of 1905; this J., 1906, 846.—T. F. B.

Salt; Process for making common ——. G. T. Holloway. Fr. Pat. 366,904, June 6, 1906.

See Eng. Pat. 16,279 of 1905; this J., 1906, 758.—T. F. B.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 1046.)

ENGLISH PATENT.

Waste sand from glass-works commonly known as burgy; Treatment and utilisation of —— [as filling material for linoleum, leather, paper, &c.]. W. Thompson, Birkenhead. Eng. Pat. 26,893, Dec. 23, 1905.

THE waste sand or burgy from plate glass works is levigated, and the finest portions are used as a filling in making linoleum, brown paper, "American" cloth, or leather, boot soles and heels, floor coverings, &c.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 1046.)

Wood supply of the world. Ch. of Com. J., 1906. [T.R.]

THE American Consul at Eibenstock, reporting on the world's supply of wood, states that the demand, instead of diminishing, as was expected when coal came in use as a substitute for wood, has gone on increasing, until the question of a continued supply to meet the present rapidly increasing rate of consumption is a very serious problem. The coal mines of Belgium called for 1,742,740 square yards of wood in 1903. Each year a renewal of old supports is taking place, and new ones are being put into new galleries. Railroads use enormous quantities of wood in sleepers. The following table shows the importations of wood into the countries named:—

	Cub. yds.
England	16,342,600
Germany	11,766,667
France	8,496,300
Belgium	1,897,777
Italy	915,148
Denmark	849,630
Spain	392,222
Switzerland	313,778

The exportation of wood from the centres named below was as follows:—

	Cub. yds.
Russia*	9,544,074
Sweden	8,328,180
Austria-Hungary	6,929,260
Finland	4,340,451
Norway	1,961,110
Bosnia-Herzegovina	542,574

* Exclusive of Finland.

North America, Siberia, Africa, India, China, Korea, and South America still contain great unutilised and almost unknown forests. Many African forests are really composed of nothing better than thin bushes, and Siberia is already being systematically subjected to de-foresting, which will also begin in Korea in the near future. North America, however, at one time the wood storehouse for the world, has not now enough wood to supply its own demand, notwithstanding its 506,555,000 acres of wooded area. It now depends upon Canada, which, with its 798,133,000 acres of forests, represents probably the largest single area of any country in the world.

Timber; Experiments on the strength of treated ——. W. K. Hatt. U.S. Dept. of Agric., Circular No. 39, 31 pages.

THIS circular gives an account of an investigation of processes of preserving timber, and the influence of the processes upon the strength of the wood. The tests were confined to sap-wood, both green and seasoned, and were made upon 11-ft. railroad sleepers, and upon small pieces cut from them. The only preservatives used were zinc chloride and creosote. Tests were made of bending, compression parallel to the grain (both static and impact), compression at right angles to the grain, and shearing (static). The tests were made upon untreated pieces, treated pieces, and treated pieces that were, if necessary, re-soaked to restore the original degree of moisture. The capacity of the wood to hold a spike was also determined, and the physical characteristics of the wood noted. The results of the tests are given in a number of tables, and the following general conclusions are drawn from them:—The steaming process is injurious to wood, if it is continued too long or beyond a certain pressure (temperature). The injurious effects, or otherwise, also depend upon the quality of the wood, and its degree of seasoning. For one wood tested (loblolly pine) the limits were 30 lb. for four hours, or 20 lb. for six hours; beyond

these the wood was scorched and became discoloured. Up to a certain duration of the steaming process the weight of the sleepers increased, but beyond that point, the increase in weight was negligible. Greenwood that had been steamed and saturated, showed weakness in proportion to the duration of the steaming process and the pressure attained therein, but if air-dried the specimens regained the greater part of their strength, provided the steaming process had not exceeded the limits of safety. The dried specimens, if again immersed in water, were weaker than natural wood similarly dried and re-soaked. Wood treated with zinc chloride was not weaker than steamed wood under static loading, but was weaker under impact, and also weaker than natural wood. The presence of creosote does not of itself affect the strength of the wood, probably because it does not enter the cell walls, but only fills the openings of the cells. It does however retard the rate at which wood will season. The steamed and creosoted wood was weaker than the natural wood, but not weaker than the steamed wood.—W. C. H.

Plaster of Paris; Researches on ——. De Forcrand. Bull. Soc. Chim., 1906, **35**, 781–790.

The author has made some experiments on the heats of solution in water of the various modifications of calcium sulphate. For gypsum, $CaSO_4.2H_2O$, he accepts Thomsen's value of 330 calories with reserve; for the hemi-hydrate, $CaSO_4.\frac{1}{2}H_2O$, he finds 3560; for anhydrous calcium sulphate, $CaSO_4$, prepared at 155° C., 5655; and prepared at a red heat, 2920; Thomsen's value for anhydrous calcium sulphate prepared at a low temperature being only 4440 calories. The author believes that anhydrous calcium sulphate consists of a polymeric modification, which is incapable of changing to the hemihydrate in presence of water, the formation of hemihydrate with its high degree of solubility in water being necessary for the formation of the difficultly soluble hydrate, $CaSO_4.2H_2O$. On the other hand, anhydrous calcium sulphate formed at low temperatures is not condensed, and readily takes up water to form the hemihydrate, which then passes into solution, the dihydrate $CaSO_4.2H_2O$ crystallising out.—A. G. L.

Portland cements; Some conditions influencing constancy of volume in ——. E. D. Campbell and A. H. White. J. Amer. Chem. Soc., 1906, **28**, 1273—1303.

A series of experiments has been made with the view of studying the effect of changes in chemical composition upon the properties, especially the constancy of volume of finished cement. The present paper deals with cements, not very highly limed, in which the percentages of alumina and iron oxide are together less than half of the silica. The tests were made with bars of neat cement, and the changes of volume were determined by direct micrometric measurements; added materials, such as sand or crushed stone, act simply as diluents, so far as constancy of volume is concerned, and would render the results less comparable. The detailed results are set out in tables. They show that free lime in Portland cement is not slaked during the mixing and setting of the cement, nor does it become completely hydrated until after about 14 days, even when the cement is immersed in water. This gradual slaking is the cause of the abnormal expansion of cements containing free lime. When the cement is kept under water, any evil effects due to the presence of free lime are shown within two months; when the cement is employed in places where it is usually dry, the expansion due to hydration of free lime will be more gradual, but several times greater in volume, and after several months may become so great as to cause complete disintegration. Cement containing free lime can be rendered quite safe by ageing the ground cement, or by exposing the clinker to the weather, until a pat will show a perfect boiling test. An exposure of three months is usually sufficient in the case of clinker, whilst under favourable conditions, ground cement may be properly aged in one month. The boiling test affords a reliable method for detecting the presence of free lime.

Combined magnesia, like combined lime, has no injurious effect on the constancy of volume of Portland cement, nor has free magnesia any appreciable influence when the cement is used in places where it is always dry. In cases where the cement is wet for a part or the whole of the time, however, free magnesia is very injurious owing to its very slow hydration and consequent expansion. The expansion is not appreciable until after two months even when the cement is kept immersed in water; it becomes distinctly evident after a year, and continues at an increasing rate for at least five years and probably longer. The deleterious effect of free magnesia is not destroyed by ageing the cement. Free magnesia cannot be detected with certainty by the boiling test. The slow hydration of free magnesia is probably the cause of the expansion, frequently accompanied by more or less complete disintegration often observed in cement structures after the lapse of several years. When raw materials containing magnesium carbonate are used, if care be taken to grind them extremely fine (see this J., 1903, 1348), then where the amount of total magnesia does not exceed 3 per cent., a well-made cement should not contain sufficient free magnesia to produce injurious expansion under any conditions of practice. In structures where suitable provision can be made for expansion joints, more than 3 per cent. of total magnesia may be allowed, but even under these circumstances the amount should not exceed 5 per cent. Cement intended for use where constancy of volume is of paramount importance should always be aged; a disadvantage of this course is that the cement tends to become very quick-setting, but if the ageing be continued for a sufficiently long period, the cement becomes slow-setting again. (See also this J., 1902, 1396.).—A. S.

English Patents.

Stone; Artificial ——. T. M. Thom, Cheshunt, Herts. Eng. Pat. 20,070, Oct. 4, 1905.

The object of this invention is the production of artificial limestone for building purposes. The *débris* from quarrying and dressing stone is crushed and screened to reduce it to its natural granular condition. The crushed material is mixed with lime, with or without the addition of colouring matter, and the mixture slaked and moulded into blocks which are dried and finally carbonated. Building material so made is claimed as a new article of manufacture. (See also Eng. Pat. 13,467 of 1900; this J., 1901, 719.)—W. C. H.

Stone, blocks, pipes, and briquettes from slag; Manufacture of artificial ——. A. J. Boult, London. From Cäln Müsener Bergwerks Aktien-Verein, Crouzthal, Germany. Eng. Pat. 2207, Jan. 29, 1906.

See Fr. Pat. 362,808 of 1906; this J., 1906, 760.—T. F. B.

Bricks; Burning — —, and kilns therefor. J. Parkes, West Bromwich, Staffs. Eng. Pat. 20,153, Oct. 5, 1905.

The improved method of burning bricks in a kiln, consists in first causing the heat to pass upward from the firing holes to and through the bricks in the upper part of the kiln, and down through the mass to the main heating flue in the floor of the kiln, and when these bricks have been sufficiently burnt, causing the heat to pass directly from the firing holes, through holes in the back walls of the firing holes, to the bricks in the lower part of the kiln, thence to the main heating flue. To put this method into practice the back walls of the firing holes are provided with a loose brick or stopper, which can be pushed into the kiln at the proper time of the burning, to allow heat to pass directly into the lower part of the kiln from the firing holes. Reference is made to Eng. Pat. 22,562 of 1891.—W. C. H.

Tunnel kilns for burning bricks, briquettes, and the like. E. R. Sutcliffe and F. Speakman, both of Leigh, Lancs. Eng. Pat. 20,646, Oct. 12, 1905.

In a tunnel kiln, for continuously drying, burning, and cooling bricks, &c., a movable damper is arranged between the cooling and combustion chambers, which, when lowered, deflects the air, heated by its passage over the burnt bricks, into side flues which conduct the air into flues connecting the furnaces, or firing holes, with the combustion chamber. Along the whole length of the kiln

is an air supply passage in the floor of the kiln, and below the wagon platforms, which are consequently cooled by the incoming air; the air from this passage enters the further end of the cooling chamber. There is an outlet from the drying chamber, and means are provided for producing the necessary draught through the kiln. The wagon platforms fit into grooves at the sides of the kiln, which is thus divided into two horizontal portions, through the lower of which the incoming air passes. The damper between the cooling and combustion chambers touches a wagon platform, and thus forms a cross-partition. In connection with these kilns, claim is made for use of a coal-fired furnace, connected with the combustion chamber by a flue into which the hot-air flue leads, provided with adjustable means of supplying air above and below the grate, and for supplying steam below the grate. The use of fuel-supply hoppers, provided with counterpoised bell dampers for the introduction of fuel without an undue amount of cold air, is also claimed. By a modification of the kiln, by a suitable arrangement of the flues, heated air can be taken direct from the cooling chamber to the drying chamber, and the products of combustion can be taken direct from the combustion chamber, and not allowed to enter the drying chamber, either by a separate flue to the stack, or by a separate stack.—W. C. H.

Bricks; Manufacture of ——. A. Gordon, Weiser, Id., U.S.A. Eng. Pat. 7927, April 2, 1906. Under Int. Conv., May 4, 1905.

See U.S. Pat. 809,053 of 1906; this J., 1906, 123.—T. F. B

Wood and goods of different kinds; Apparatus for heating, steaming, and chemically treating ——, *and for drying such goods.* C. McWhirter, London. Eng. Pat. 6681, March 20, 1906.

The present patent relates to a modified form of the apparatus described in Eng. Pat. 14,869 of 1904 (this J., 1905, 443). The apparatus consists of an oven or boiler, within which is a steam generator, heated by a coil through which high-pressure steam is passed. Steam is passed from the inner generator through a pipe controlled by a valve into the oven or boiler; in order to produce a vacuum in the oven, it is provided with an ejector, steam-tight cover, safety-valve, &c. Reference is made to Eng. Pat. 4636 of 1885.—W. C. H.

United States Patents.

Kiln for burning clayware. F. W. Butterworth, Danville, Ill. U.S. Pat. 826,831, July 24, 1906.

The kiln consists essentially of a vertical shaft, joined near its bottom to a chamber slightly inclined to the horizontal. The furnace gases are introduced near the top of the shaft, pass down it, and then go up the inclined chamber, being then drawn by a fan into a chimney. The raw clay goods (bricks, &c.) are stacked on trucks which roll by their own weight down the inclined chamber, on to the top of a hydraulic elevator, placed at the bottom of the shaft. This elevator raises one truck at a time to a point in the shaft corresponding to the roof of the inclined chamber. At this point supporting rods are pushed below the load of bricks through holes in the kiln, in such a way as to relieve the truck entirely of the weight of the load; the trucks are constructed of I-beams placed longitudinally on the axles in such a way as to facilitate this operation. The elevator with the empty truck then sinks; the truck is removed through an opening in the shaft opposite to the inclined chamber; the next truck is raised on the elevator after withdrawing the supporting rods, and all the operations repeated. In this way a practically continuous movement of the bricks up the shaft, and their gradual burning is secured. At the top of the shaft a similar method of introducing supporting rods into the spaces between the bricks is used for withdrawing a truckful of burnt bricks at a time. Air is supplied at various points in the kiln to promote combustion, and also to cool the burnt bricks at the top somewhat rapidly to permit of their handling.—A. G. L.

Cement; Apparatus for producing ——. R. C. Carpenter, Ithaca, N.Y. U.S. Pat. 833,918, Oct. 23, 1906.

The upper end of a rotary cement kiln is connected with a hood from which the burnt gases from the kiln pass to an economiser and an upright water-tube boiler having widely spaced vertical tubes. The gases are finally drawn by an exhaust fan into a stack. The boiler is provided with an auxiliary furnace, situated close to the hoods, and provided with suitable flues and dampers. —A. G. L.

Cement; Magnesium ——, *and process of manufacturing same.* W. Jeroch, Berlin. U.S. Pat. 833,930, Oct. 23, 1906.

See Fr. Pat. 363,103 of 1906; this J., 1906, 848.—T. F. B.

French Patents.

Marble, granite, &c.; Manufacture of artificial ——. L. Lefranc. First Addition, dated May 26, 1906, to Fr. Pat. 355,222, of May 23, 1905 (this J., 1905, 1173).

By running the molecular mixture of fused fluorspar and calcium sulphate, entitled "spathite" and claimed in the principal patent, into moulds containing flints, pebbles, &c., a kind of concrete is obtained. By suitable disposition of the flints, &c., to which carborundum may also be added, in the moulds, patterns may be obtained. Or else, the moulds may contain a metallic skeleton, instead of the flints, &c., in which case a reinforced "spathite," similar to reinforced concrete is obtained. Finally, the calcium sulphate may be replaced by barium sulphate, or strontium sulphate, or by a mixture of the two.—A. G. L.

Silicates of lime; Process for increasing the binding power of basic ——. W. Schumacher. Fr. Pat. 366,755, June 1, 1906.

The binding power of basic silicates of lime, *e.g.*, Portland cement, blast-furnace slag, &c., is greatly increased by adding finely powdered quartz, and submitting the mixture to the action of steam under pressure.—A. G. L.

Agglomerate for building materials, and process of making the same. C. Gramiccia. Fr. Pat. 366,879, June 5, 1906.

Volcanic scoriæ, puzzuolana, tufa, &c., is mixed with one-twelfth its weight of well-slaked lime, compressed into bricks, tiles, &c., and treated for 10 hours in an autoclave under a pressure of six to eight atmospheres. The bricks, &c., obtained are claimed to be of great strength. If they are then burnt, a very refractory material is said to be obtained. The scoriæ, &c., may be partly replaced by sand, gravel, or calcareous material; in the last case a little cement is also added. In any case a suitable colouring material may be added.—A. G. L.

Clay and similar plastic materials; Method of treating ——. A. A. Scott. Fr. Pat. 367,775, July 5, 1906.

See U.S. Pats. 816,385 and 816,386 of 1906; this J., 1906, 427 and 428.—T. F. B.

X.—METALLURGY.

(*Continued from page* 1052.)

High carbon steels; Heat treatment of some ——. W. Campbell. J. Amer. Chem. Soc., 1906, **28**, 1304—1322.

The author gives an account of some work carried out in conjunction with Committee F on the "Heat Treatment of Steel," American Society for Testing Materials. The steels examined had the following composition:—

No.	C.	Mn.	P.	Si.	S.
1	2·04	0·28	0·014	—	0·014
2	1·94	0·20	0·009	0·17	0·013
3	1·72	0·075	0·013	0·20	0·013
4	1·61	0·19	0·013	0·19	0·013
5	1·04	0·13	0·012	—	0·017
6	0·70	0·068	0·012	0·141	0·019

these the wood was scorched and became discoloured. Up to a certain duration of the steaming process the weight of the sleepers increased, but beyond that point, the increase in weight was negligible. Greenwood that had been steamed and saturated, showed weakness in proportion to the duration of the steaming process and the pressure attained therein, but if air-dried the specimens regained the greater part of their strength, provided the steaming process had not exceeded the limits of safety. The dried specimens, if again immersed in water, were weaker than natural wood similarly dried and re-soaked. Wood treated with zinc chloride was not weaker than steamed wood under static loading, but was weaker under impact, and also weaker than natural wood. The presence of creosote does not of itself affect the strength of the wood, probably because it does not enter the cell walls, but only fills the openings of the cells. It does however retard the rate at which wood will season. The steamed and creosoted wood was weaker than the natural wood, but not weaker than the steamed wood.—W. C. H.

Plaster of Paris; Researches on ——. De Forcrand. Bull. Soc. Chim., 1906, **35**, 781–790.

The author has made some experiments on the heats of solution in water of the various modifications of calcium sulphate. For gypsum, $CaSO_4.2H_2O$, he accepts Thomsen's value of 330 calories with reserve; for the hemi-hydrate, $CaSO_4.\frac{1}{2}H_2O$, he finds 3560; for anhydrous calcium sulphate, $CaSO_4$, prepared at 155° C., 5655; and prepared at a red heat, 2920; Thomsen's value for anhydrous calcium sulphate prepared at a low temperature being only 4440 calories. The author believes that anhydrous calcium sulphate consists of a polymeric modification, which is incapable of changing to the hemihydrate in presence of water, the formation of hemihydrate with its high degree of solubility in water being necessary for the formation of the difficultly soluble hydrate, $CaSO_4.2H_2O$. Tunnel kilns for burning bricks, briquettes, and the like. E. R. Sutcliffe and F. Speakman, both of Leigh, Lancs. Eng. Pat. 20,646, Oct. 12, 1905.

In a tunnel kiln, for continuously drying, burning, and cooling bricks, &c., a movable damper is arranged between the cooling and combustion chambers, which, when lowered, deflects the air, heated by its passage over the burnt bricks, into side flues which conduct the air into flues connecting the furnaces, or firing holes, with the combustion chamber. Along the whole length of the kiln

storm, become charged with electricity, and that the "backstroke," or the sudden discharge of the inducing cloud, might cause a spark. This danger is remote, but it is easily and completely provided against by good earth-connection.—J. T. D.

Nitrides of zinc, aluminium, and iron. A. H. White and L. Kirschbraun. J. Amer. Chem. Soc., 1906, **28**, 1343—1350.

THE most favourable temperature for the action of dry ammonia gas on zinc dust is 600° C., but the nitride produced decomposes to a considerable extent even at its temperature of formation, and cannot therefore be obtained in a pure state by this method. The purest specimen obtained by the authors contained 10·6 per cent. of nitrogen as compared with the 12·52 per cent. required by the formula, Zn_3N_2. The product has properties similar to those of the nitride, Zn_3N_2, prepared by Frankland (Phil. Mag., **15** [4], 149) by heating zinc amide. It is probably a solid solution of the nitride in metallic zinc (compare Baur and Voerman, Z. physik. Chem., **32**, 467). Finely-divided aluminium and iron are also attacked by ammonia gas, the most favourable temperatures being 700° and 450°—475° C. respectively. The best preparation from aluminium contained 1·8 per cent. and from iron 10·1 per cent. of nitrogen. The iron preparations are regarded by the authors as solid solutions of iron nitride, Fe_3N_2, in metallic iron.—A. S.

Molybdenum; Preparation of fused ——. H. Biltz and R. Gärtner. Ber., 1906, **39**, 3370—3371.

THE aluminothermic preparation of molybdenum has hitherto given a very poor yield, on account of the volatility of molybdenum trioxide. The authors find that the yield is largely increased by substituting the dioxide for the trioxide. The dioxide is easily obtained by reducing the trioxide at a red heat in a stream of hydrogen; 80 grms. of it fired with 21 grms. of aluminium powder yielded 52 grms. (calc. 55½) of melted molybdenum of 98·6 per cent.—J. T. D.

Platinum production in 1905. Mining World. [T.R.]

A REMARKABLE rise in the price of platinum and a greatly increased production in the United States took place in 1905. Early in March, 1905, the price of ingot platinum advanced from $19.50 per ounce to $21, thus surpassing that of gold. On April 1, 1905, the price fell to $20.50, and remained firm at this quotation until February 1, 1906, when it rose to $25, where it remained until Sept. 1, when it leaped to $34. The production of platinum in the United States increased from 200 oz. in 1904 to 318 oz. in 1905. The rise in the price of platinum and its increased production in America may be ascribed to the growing demand and to the reduced yield of the Russian placers. This reduction of the output is due to the fact that the entire product for a varying term of years was bought up under contract and at prices that now seem ridiculously low. As the mine owners receive only the fixed price, they do not participate in any gain due to rise in value, and are therefore not desirous of a large production, but are husbanding the limited resources of their mines until such time as they can dispose of their product to better advantage. Meanwhile the small mines, which, generally speaking, are not hampered by such agreements, are working to their full capacity, to take advantage of the stimulated prices; but their entire output is only a small percentage of what is usually produced. A greatly increased consumption of platinum in the electrical and chemical industries, together with this stringency of supply, accounts for the prevailing high prices. The examination of black sands commenced in 1905 by the United States Geological Survey has done much toward placing platinum mining in America upon a stable footing, and developing it into a permanent and profitable industry. Not only have many discoveries of platinum in new localities been made, but the tests have revealed the fact that there are districts which contain surprising quantities of platinum. Platinum is now known to exist in California, Oregon, Idaho, Colorado, Washington, Montana, Utah, Arizona, and in Wyoming. The metal is also rarely found in Alaska, and in the gold-bearing sands of Corosal River, Porto Rico. Isolated occurrences of single nuggets or mere traces of the metal have been found in many other counties of these states, as well as in four of the eastern states, namely, New York, Pennsylvania, North Carolina and Georgia. In many of these localities the metal occurs but sparingly. The more promising fields are in the counties of southern Oregon and northern California. With proper methods a considerable annual output should be obtained. The platinum metals are usually found in working gold placers, especially where the gravels are derived from peridotites. Many have been convinced for a long time that it would pay to save the platinum in the gravels, if it could be done by some inexpensive method. The experiments of the United States Geological Survey have shown conclusively that 95 to 98 per cent. of the precious metals, both gold and platinum, contained in the sluice box sands, can be saved on concentrating tables of the Linder or Wilfley type, such as are used in everyday practice; and that in most cases the concentrates thus obtained will represent less than 1 per cent. of the total weight of sand fed to the table; a test on 15 oz. of black sand, recovered from 200 lb. of original gravel, yielded 0·7 grm. of platinum, and 0·023 grm. of irodosmium. The imports of platinum into the United States during 1905 were valued at $2,173,263, as against $1,879,155 in 1904, an increase of $294,108.

Mineral industry of Peru. Bd. of Trade J., Nov. 1, 1906. [T.R.]

DURING the first half of 1903, the number of mining claims recorded in the register was 5,310, subject to a charge of £9,752, while the register of the first half of 1906 contains 10,421 mining claims, which pay in taxes, fines, &c., £32,357. The following is a *résumé* of the mineral production during 1905:—

ENGLISH PATENTS.

Ores; Dry concentration of ——. A. J. Boult, London. From H. M. Sutton, W. L. Steele, and E. G. Steele, Dallas, Texas. Eng. Pat. 17,561, Aug. 30, 1905.

SEE Fr. Pat. 366,685 of 1906; this J., 1906, 1052.—A. G. L.

Sulphide ores; Treatment of ——. J. E. Bousfield, London. From F. Mackay, Melbourne, and A. J. Beckwith, South Yarra, Australia. Eng. Pat. 20,380, Oct. 9, 1905.

GOLD, silver, zinc, lead, and other metals are obtained from complex sulphide ores by finely powdering the ores, and blowing the powder, mixed with air, into a chamber previously heated by producer gas to the ignition point of the sulphide ores. The air current keeps the powder in suspension in the chamber, and oxidises it, a fume consisting of zinc oxide, lead sulphate, &c., being obtained besides gases containing sulphur dioxide and trioxide. If the ore is not rich enough in sulphides to maintain the chamber at the temperature necessary

for their proper oxidation, extraneous heat may be supplied, or coal-dust or producer gas blown in. The fume and ore dust obtained are either passed into settling chambers or filtering apparatus, or they may be passed into wet condensation chambers. The zinc oxide may be leached out from the lead sulphate by treatment with sulphuric acid, which may be made from the oxides of sulphur contained in the gases obtained by the reaction. The insoluble residue may then be smelted as usual.
—A. G. L.

Sulphide ores or compounds; Reduction of ——. C. P. Townsend, Washington, U.S.A. Eng. Pat. 6569, March 19, 1906.

SEE U.S. Pat. 815,881 of 1906; this J., 1906, 381.— T.F.B.

[*Gold and silver*] *metals; Extraction of* —— *from their ores.* J. Turton, Johannesburg, Transvaal. Eng. Pat. 25,672, Dec. 9, 1905.

THE process described is designed especially for the extraction of gold and silver, but may also be used for platinum and base metals. It consists in systematically treating the powdered ore, after roasting if it contains pyrites, in vats with a solution containing: water, 400 lb.; sulphuric acid, 80; sodium chloride, 40; sodium or potassium nitrate, 22½; sodium or potassium permanganate, 2; and saccharin, about 2 lb. The vats used may be made of pitch-pine bound with iron bands, or of bricks lined with "non-perishable" cement on a concrete foundation, or of other acid-proof materials. The solution is always brought up to its original strength in passing from vat to vat by suitable additions. When it has become saturated with gold (or other metals) it is diluted with from three to five parts of water, and the diluted solution is passed through charcoal, which may be enclosed in bags of muslin. The charcoal retains the gold, which is recovered by burning the charcoal, and fluxing the ashes as usual.—A. G. L.

Goldschmidt or alumino-thermic process; Impts. in the ——. H. Goldschmidt, Essen on the Ruhr, Germany. Eng. Pat. 926, Jan. 12, 1906.

SEE Addition of Jan. 10, 1906, to Fr. Pat. 361,197 of 1905; this J., 1906, 765.—T. F. B.

[*Thermite.*] *Mixtures for heating by reduction of metallic compounds.* P. Jensen, London. From E. Maemecke, Berlin. Eng. Pat. 3089, Feb. 8, 1906.

A MATERIAL similar to thermite is obtained by mixing 15 per cent. by weight of granulated magnesium, 10 per cent. of granulated silicon, and 75 per cent. of magnetic oxide of iron, Fe_3O_4, or ferric oxide, Fe_2O_3, or of a mixture of the two, a liquid slag corresponding approximately to the formula $3\frac{1}{2}$ MgO, $2SiO_2$ being obtained, together with an "appreciable amount" of molten iron. The proportions of the ingredients may be varied from 9 per cent. of magnesium, 13 of silicon, and 78 of magnetic oxide, to 21 per cent. of magnesium, 6 of silicon, and 73 of magnetic oxide. The magnesium may be partly replaced by aluminium, calcium, barium, strontium, sodium, or the like, and the silicon may be used in the form of high-grade ferro-silicon. The iron oxide may be partly or wholly replaced by oxides of chromium, manganese, molybdenum, &c., and metals such as copper may be added to the molten mass if it is desired to produce alloys. The process may also be used for welding. (See also Fr. Pat. 364,312, this J., 1906, 936.)—A. G. L.

UNITED STATES PATENTS.

Metal-bearing ores, &c.; Treating refractory ——. J. W. H. James, Media, Pa. U.S. Pat. 833,394, Oct. 16, 1906.

THE ore is passed in a loose state through a retort, heated externally, from which air is excluded, and in which water-gas is generated. The escaping water-gas is treated for the removal of other gases and volatile compounds carried off from the ore.—A. S.

Ores; Method of smelting ——. A. J. Mason, Assignor to F. K. Hoover, Chicago, Ill. U.S. Pat. 833,406, Oct. 16, 1906.

THIN streams of flux and of ore, both in a finely-divided condition, are caused to impinge one upon the other, and the resulting stream of mixed ore and flux is directed into a reducing and smelting chamber, wherein it is subjected to the action of a forced blast of burning air and fuel, impinged upon it in a substantially transverse direction. The stream of partially-reduced and melted ore is then directed upon an incandescent bed of carbonaceous material such as coke. The hot waste gases are utilised for the preliminary heating of the air, fuel, ore, and fluxes.—A. S.

Ores; Process of briquetting friable ——. C. Reinke, Bredelar, Germany. U.S. Pat. 833,630, Oct. 16, 1906.

SEE Eng. Pat. 19,464 of 1904; this J., 1905, 974.—T. F. B.

Treating substances [*Ores, &c.*] *by the aid of heat; Process of* ——. W. B. Dennis, Blackbutte, Oreg. U.S. Pat. 833,679, Oct. 16, 1906.

THE ore receives a preliminary heating from the escaping gas current, and is then divided into portions which are progressively heated by a burning mixture of gas and air. Both the gas and the ore or other material treated, travel in the same general direction through the apparatus, and both leave it at the hottest end. To keep up the temperature fresh supplies of air and gas are introduced at intervals. (See following abstract.)—W. H. C.

Treating substances [*Ores, &c.*] *by the aid of heat; Apparatus for* ——. W. B. Dennis, Blackbutte, Oreg. U.S. Pat. 833,680, Oct. 16, 1906.

THE claim is for an apparatus in which the process described in the preceding abstract can be carried out, and consisting essentially of a vertical tower furnace down which the ore or other material is caused to pass. The inner space of the tower is divided into a series of chambers by horizontal grates, the alternate bars of which are fixed and movable, so that by turning the movable bars from without the furnace, the ore can be let down from chamber to chamber to the bottom where it falls into a discharge apparatus. The air and gas enter through ducts in the walls of the furnace from which they pass to primary and secondary combustion chambers formed on opposite sides of the grates. These are alternately on opposite sides of the chambers so that they face one another. The gases pass across the chambers downwards from the cooler to the hotter part of the furnace, receiving fresh supplies in each chamber, and then enter a dust-separating chamber from which they again pass up through flues in the furnace wall to the top, where they pass to the apparatus where the preliminary heating of the ore is effected.—W. H. C.

Metals [*Zinc, &c.*], *and compounds thereof; Process of obtaining* ——. H. Mehner, Berlin. U.S. Pat. 833,472, Oct. 16, 1906.

ZINC ore is added to a molten and incandescent silicate, and the fluid compound is caused to pass through an excess of carbon. Air is admitted to the vapours generated, in order to produce zinc oxide, which, with the gases, is led away for separation. The impoverished silicate is collected after passage through the fragments of carbon, and is reheated with further addition of zinc ore, to repeat the process.—E. S.

storm, become charged with electricity, and that the "backstroke," or the sudden discharge of the inducing cloud, might cause a spark. This danger is remote, but it is easily and completely provided against by good earth-connection.—J. T. D.

Nitrides of zinc, aluminium, and iron. A. H. White and L. Kirschbraun. J. Amer. Chem. Soc., 1906, **28**, 1343—1350.

THE most favourable temperature for the action of dry ammonia gas on zinc dust is 600° C., but the nitride produced decomposes to a considerable extent even at its temperature of formation, and cannot therefore be obtained in a pure state by this method. The purest specimen obtained by the authors contained 10·6 per cent. of nitrogen as compared with the 12·52 per cent. required by the formula, Zn_3N_2. The product has properties similar to those of the nitride, Zn_3N_2, prepared by Frankland (Phil. Mag., **15** [4], 149) by heating zinc amide. It is probably a solid solution of the nitride in metallic zinc (compare Baur and Voerman, Z. physik. Chem., **32**, 467). Finely-divided aluminium and iron are also attacked by ammonia gas, the most favourable temperatures being 700° and 450°—475° C. respectively. The best preparation from aluminium contained 1·8 per cent. and from iron 10·1 per cent. of nitrogen. The iron preparations are regarded by the authors as solid solutions of iron nitride, Fe_3N_2, in metallic iron.—A. S.

Molybdenum; Preparation of fused ——. H. Biltz and R. Gärtner. Ber., 1906, **39**, 3370—3371.

THE aluminothermic preparation of molybdenum has hitherto given a very poor yield, on account of the volatility of molybdenum trioxide. The authors find that the yield is largely increased by substituting the dioxide for the trioxide. The dioxide is easily obtained by reducing the trioxide at a red heat in a stream of hydrogen; 80 grms. of it fired with 21 grms. of aluminium powder yielded 52 grms. (calc. 55½) of melted molybdenum of 98·6 per cent.—J. T. D.

Platinum production in 1905. Mining World. [T.R.]

A REMARKABLE rise in the price of platinum and a greatly increased production in the United States took place in 1905. Early in March, 1905, the price of ingot platinum advanced from $19.50 per ounce to $21, thus surpassing that of gold. On April 1, 1905, the price fell to $20.50, and remained firm at this quotation until February 1, 1906, when it rose to $25, where it remained until Sept. 1, when it leaped to $34. The production of platinum in the United States increased from 200 oz. in 1904 to 318 oz. in 1905. The rise in the price of platinum and its increased production in America may be ascribed to the growing demand and to the reduced yield of the Russian placers. This reduction of the output is due to the fact that the entire product for a varying term of years was bought up under contract and at prices that now seem ridiculously low. As the mine owners receive only the fixed price, they do not participate in any gain due to rise in value, and are therefore not desirous of a large production, but are husbanding the limited resources of their mines until such time as they can dispose of their product to better advantage. Meanwhile the small mines, which, generally speaking, are not hampered by such agreements, are working to their full capacity, to take advantage of the stimulated prices; but their entire output is only a small percentage of what is usually produced. A greatly increased consumption of platinum in the electrical and chemical industries, together with this stringency of supply, accounts for the prevailing high prices. The examination of black sands commenced in 1905 by the United States Geological Survey has done much toward placing platinum mining in America upon a stable footing, and developing it into a permanent and profitable industry. Not only have many discoveries of platinum in new localities been made, but the tests have revealed the fact that there are districts which contain surprising quantities of platinum. Platinum is now known to exist in California, Oregon, Idaho, Colorado, Washington, Montana, Utah, Arizona, and in Wyoming. The metal is also rarely found in Alaska, and in the gold-bearing sands of Corosal River, Porto Rico. Isolated occurrences of single nuggets or mere traces of the metal have been found in many other counties of these states, as well as in four of the eastern states, namely, New York, Pennsylvania, North Carolina and Georgia. In many of these localities the metal occurs but sparingly. The more promising fields are in the counties of southern Oregon and northern California. With proper methods a considerable annual output should be obtained. The platinum metals are usually found in working gold placers, especially where the gravels are derived from peridotites. Many have been convinced for a long time that it would pay to save the platinum in the gravels, if it could be done by some inexpensive method. The experiments of the United States Geological Survey have shown conclusively that 95 to 98 per cent. of the precious metals, both gold and platinum, contained in the sluice box sands, can be saved on concentrating tables of the Linder or Wilfley type, such as are used in everyday practice; and that in most cases the concentrates thus obtained will represent less than 1 per cent. of the total weight of sand fed to the table; a test on 15 oz. of black sand, recovered from 200 lb. of original gravel, yielded 0·7 grm. of platinum, and 0·023 grm. of irodosmium. The imports of platinum into the United States during 1905 were valued at $2,173,263, as against $1,879,155 in 1904, an increase of $294,108.

Mineral industry of Peru. Bd. of Trade J., Nov. 1, 1906. [T.R.]

DURING the first half of 1903, the number of mining claims recorded in the register was 5,310, subject to a charge of £9,752, while the register of the first half of 1906 contains 10,421 mining claims, which pay in taxes, fines, &c., £32,357. Sulphide ores; Treatment of ——. J. E. Bousfield, London. From F. Mackay, Melbourne, and A. J. Beckwith, South Yarra, Australia. Eng. Pat. 20,380, Oct. 9, 1905.

GOLD, silver, zinc, lead, and other metals are obtained from complex sulphide ores by finely powdering the ores, and blowing the powder, mixed with air, into a chamber previously heated by producer gas to the ignition point of the sulphide ores. The air current keeps the powder in suspension in the chamber, and oxidises it, a fume consisting of zinc oxide, lead sulphate, &c., being obtained besides gases containing sulphur dioxide and trioxide. If the ore is not rich enough in sulphides to maintain the chamber at the temperature necessary

passed through the apparatus during eight hours, resulting in the production of hypochlorite solution containing over 4 grms. of available chlorine per litre. The process of manufacture is practically automatic, the above output being obtained at a capital cost not exceeding £500, including buildings and fittings. The series system is most suitable where continuous current is available, but with alternating current, a motor-generator must be installed, and fewer cells may then be employed. At Poplar there is an increase of 1 grm. of chlorine per litre for each ten cells employed. It is stated that a warm climate does not affect the manufacture of magnesium hypochlorite.—B. N.

Oxides and sulphides; Conductivity of ——. J. Konigsberger and O. Reichenheim. Physikal. Zeits., 1906, 570—578. Electrician, 1906, 58, 100—101.

The electric conductivities of natural crystals of specular iron ore, iron pyrites, galena, and marcasite, were determined at temperatures between −130° C. and +240° C. The higher the temperature, the more closely did the electrical behaviour resemble that of a metal; the lower the temperature, the more pronounced was the increase of resistance. No chemical action could be detected during the passage of the electric current, and the authors conclude that the conduction of these oxides and sulphides cannot be of an electrolytic nature.—T. F. B.

Sodium hypochlorite; Depreciation of electrolytically produced solutions of ——. W. P. Digby. VII., page 1093.

English Patents.

Cathodes. H. S. Hatfield and The Reason Manufacturing Co., Ltd., Brighton. Eng. Pat. 20,770, Oct. 13, 1905.

(*B.*)—ELECTRO-METALLURGY.

Gold; Electrolytic precipitation of ——, *with the use of a rotating anode, [and electrolytic analysis of alkali halides].* J. R. Withrow. J. Amer. Chem. Soc., 1906, 28, 1350—1357.

The author has made experiments to ascertain the best conditions for the rapid electrolytic deposition of gold. The apparatus used was similar to that described by Ingham (this J., 1904, 1114). The conditions under which the best results were obtained in cyanide solutions were as follows:—

Gold taken.	KCN.	Dilution.	Current.	E.M.F.	Speed of anode.	Time.	Gold found.
grms.	grms.	c.c.	ampères.	volts.	Revs. per min.	mins.	grms.
0·2611	2·5	50	10—10·2	10—11·4	800	5	0·2612
0·2611	2·5	80	10—10·5	10—13·5	830	7	0·2611
0·5222	2·5	55	10—10·8	9·6—14·5	800	10	0·5222
0·5465	5	60	10	6·8— 7·8	790	12	0·5467

In electrolytes to which sodium sulphide solution (sp. gr. 1·165) was added, the best results were obtained under the conditions given in the following table. In these tests, the sodium sulphide solution was placed in the platinum dish serving as cathode, the anode was set in rotation, and the gold solution then run in from a pipette.

Gold taken.	Na_2S.	Dilution.	Current.	E.M.F.	Speed of anode.	Time.	Gold found.
grms.	c.c.	c.c.	ampères.	volts.	Revs. per min.	mins.	grms.
0·2878	30	60	10·1—10·3	6—6·9	840	7	0·2879
0·2878	30	60	10·2—10·5	7·4—8·8	830	7	0·2883

Some experiments were also made on the electrolytic analysis of alkali halides by a modification of Smith's method (this J., 1903, 1150), a silver-plated dish being used as anode, and a platinum spiral, rotating at 300—500 revs. per min., as cathode. Adherent deposits of silver halide were obtained, and after washing these, the alkali metal was determined by titration of the free alkali in the solution and washings.—A. S.

Micrographic examination of alloys; Application of metallic deposits in the ——. F. Giolitti. Gaz. chim. ital., 1906, **36** [2], 142—147.

In order to render the micro-structure of an alloy visible, the author recommends electrolytically coating the polished surface of the metal with a thin deposit of another metal, which can subsequently be polished or subjected to chemical treatment. The test-piece of the alloy, after being polished, can be coated either by using it as cathode in an electrolyte consisting of a dilute solution of a salt of a heavy metal, or by merely immersing it in such a solution, without the use of an electric current. In the latter case the different solution-tensions of the constituents of the alloy causes differences in the character of the deposit. In the first case, also, on using a short current-circuit and a dilute solution, the electrolytic deposit is not homogeneous, but shows the contour and structure of the different constituents. The differences in the character of the deposit can be rendered more pronounced by mechanical treatment, and by etching with suitable reagents.

Some experiments were made with a low-carbon steel, which was used as cathode in a 0·2—0·5 per cent. solution of copper sulphate, with an E.M.F. of 2—3 volts. After quite a short time the test-piece was removed, and on lightly polishing with a fine cloth, the granular structure of the ferrite showed up prominently, together with filaments of pearlite or cementite. On merely immersing a piece of the same steel in copper sulphate solution, the deposited copper adhered only to the ferrite; on subsequently polishing, the pearlite became visible. In steel containing 0·9 per cent. of carbon, ferrite and cementite were recognised. In a steel, containing 0·45 per cent. of carbon, which was heated to 825° C., cooled slowly to 690° C., and then quenched in water at 10°—15° C., the copper adhered to all of the constituents containing ferrite, but could be detached with different degrees of ease from martensite and troostite respectively. In a similar manner saturated martensite (hardenite) could be distinguished from austenite.—A. S.

Bronzes; Electrolytic corrosion of ——. B. E. Curry. Trans. Amer. Electrochem. Soc., 1906, **9**, 173—196.

Experiments by Shepherd and Blough have shown that bronzes annealed at temperatures between 200° and 400° C. can be classified as follows:—Alloys containing more than 87 per cent. of copper consist of a series of solid solutions known as α-crystals; those with from 67 to 74·5 per cent. of copper consist of another series of solid solutions, known as δ-crystals (supposed by Heycock and Neville to be the compound, Cu_4Sn), whilst those with 74·5 to 87 per cent. are composed of mixtures of α- and δ-crystals. Alloys containing from 40 to 41 per cent. of copper consist of a third series of solid solutions known as ε-crystals, those with 41 to 61·3 per cent. contain ε-crystals and the compound, Cu_3Sn, those with 61·3 to 67 per cent., mixtures of the compound, Cu_3Sn, and δ-crystals, and those with from 0—40 per cent. of copper contain crystals of tin and ε-crystals. Test-pieces of alloys containing 5, 15, 25, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, and 95 per cent. respectively of copper were used as rotating anodes in 7 per cent. solutions of sodium sulphate, sodium nitrate, sodium acetate, alkaline sodium tartrate, acid ammonium oxalate, sodium chloride, and copper sulphate, platinum wires being used as cathodes. Tests of chemical corrosion were also made by bubbling air through solutions of sodium persulphate, alkaline sodium persulphate, and sodium chloride, in which test-pieces of the alloys were immersed. The α- and δ-bronzes were annealed at 400° C., and the others at 217° C. A few experiments were also made with bronzes containing 65, 70, 75, 80, and 85 per cent. respectively of copper, after annealing at 625° C., and quenching in water. The detailed results are given in tables and curve-diagrams. It was found that the effects of chemical corrosion are practically identical with those of electrolytic corrosion. The α-bronzes corrode more rapidly than any others, and with no appreciable change of composition. The $\alpha + \delta$-bronzes become richer in tin on corrosion. The bronzes consisting of δ-crystals, δ-crystals and the compound Cu_3Sn, ε-crystals and the compound, Cu_3Sn, and ε-crystals alone are practically unaffected, and tend to become passive owing to the formation on them of a film of stannic oxide containing more or less occluded copper. The alloys consisting of ε-crystals and tin become richer in copper on corrosion, practically only tin being dissolved, in consequence of which the alloys exhibit a tendency to disintegrate. The bronzes consisting entirely of ε-crystals are more resistant than any others. None of the bronzes becomes passive in chloride solutions, alkaline tartrate solutions, and acid ammonium oxalate solutions, and none is corroded in sodium carbonate solution. An examination of laboratory water-pipes made of pure block tin showed that the protecting film on surfaces of pure tin breaks down in presence of the stronger acids, and that corrosion then takes place more rapidly. In air or in presence of oxygen and carbonic acid, the film is stable, and practically no corrosion takes place. It is pointed out that the results obtained show that the solution method for proving the existence of metallic compounds is impracticable. Heycock and Neville (Phil. Trans., 1904, 202A, 1) by this method claimed to have detected compounds of the formula, Cu_4Sn and CuSn, neither of which actually exists.—A. S.

Bronzes; Electrolytic precipitation of ——. B. E. Curry. Trans. Amer. Electrochem. Soc., 1906, **9**, 249—263.

On electrolysing the ordinary salt solutions of copper and tin, the copper is deposited first, and the solution

becomes rich in tin, so that a continuous precipitation of a bronze of definite composition is impossible under such conditions. In experiments on the electrolytic corrosion of bronzes (see preceding abstract) it had been found that, over a considerable range, bronzes dissolve quantitatively in alkaline tartrate and acid ammonium oxalate solutions. Attempts to deposit bronzes from alkaline tartrate solutions were unsuccessful, but good results were obtained with acid ammonium oxalate solutions. Electrolytes were prepared by mixing together varying proportions of the following solutions:—

Oxalic acid.	Ammonium oxalate.	Copper sulphate (cryst.)	Tin oxalate.	Water.
5 grms.	55 grms.	—	18 grms.	1 litre.
5 ,,	55 ,,	15 grms.	—	1 ,,

Experiments showed that better results were obtained by using copper chloride in place of copper sulphate. The electrodes should be rotated, and a low current density (0·2 to 2 ampères per sq. dm.) at the cathode is necessary. It is not possible to precipitate electrolytically a good bronze with less than 75 per cent. of copper.—A. S.

Sulphides; Reduction of metal, &c. ——. O. W. Brown. Trans. Amer. Electrochem. Soc., 1906, **9**, 109—115.

Molybdenum sulphide.—The author has found that molybdenite can be completely reduced to metal by smelting with lime and carbon, without any loss of metal by volatilisation of molybdenum oxide as in the usual roasting process. The molybdenite used contained 36·3 per cent. of molybdenum, 28·96 per cent. of silica, and about 5 per cent. of iron. A mixture of 160 grms. of molybdenite, 120 grms. of lime, and 84 grms of graphite, all powdered to pass a 20-mesh sieve, was smelted in a small electric resistance furnace, and about 40 grms. of white, hard metallic molybdenum were obtained. In other experiments, the charge consisted of 160 grms. of molybdenite, 112 grms. of lime, and 24 grms. of graphite, and experiments were made with various forms of electric furnace and different amounts of electrical energy. Good yields of metallic molybdenum were obtained in most cases, the fused metal being generally at the bottom of the furnace, covered by a layer of impure calcium sulphide, free from molybdenum. Analysis of a specimen of the molybdenum obtained gave the following results:—Molybdenum, 93·8; iron, 5·51; carbon, 0·87; and sulphur, 0·032 per cent. An ingot prepared by fusing together the metal obtained in several experiments was still purer, a large portion of the iron having been removed, probably by volatilisation. It contained:—molybdenum, 97·41; iron, 1·50; carbon, 1·51; and sulphur, 0·05 per cent.

Attempts to reduce the sulphides of lead, copper, iron, nickel, and antimony by smelting with lime and carbon failed to give satisfactory results.—A. S.

Molybdenum silicide; A new ——. O. P. Watts. Trans. Amer. Electrochem. Soc., 1906, **9**, 105—107.

A MIXTURE of 70 grms. of "molybdic acid, MoO_3," 30 grms. of silica, 50 grms. of boric anhydride, 106 grms. of copper, and 120 grms. of aluminium, together with some cryolite as a flux, and lime as a retarder to prevent too violent a reaction, was placed on a bed of magnesia in a horizontal electric arc furnace, and heated for 16 minutes by a current of 350 ampères at 70 volts. The ingot obtained was powdered, treated for several days with frequently renewed quantities of nitric acid (1:1), and the residue freed from silica by means of dilute hydrofluoric acid, washed with water, alcohol, and ether, and dried. In this way a product consisting of aggregations of flat, dark crystals with a metallic lustre was obtained, having the following composition:—Molybdenum, 62·4; silicon, 34·2; iron, 1·1, and boron, 2·3 per cent. By treatment with hot hydrofluoric acid, the whole of the iron was removed, and must therefore have been present as iron silicide, since iron boride is not attacked by hydrofluoric acid. If the silicon required for iron silicide, $FeSi_2$, and the molybdenum required for molybdenum boride, be deducted from the quantities present, the amounts of molybdenum and silicon remaining correspond closely with the formula, $MoSi_2$. The product is not acted upon by boiling nitric or hydrofluoric acid, or boiling *aqua regia*; it is decomposed slowly by fused sodium nitrate, and readily with incandescence, by fused sodium carbonate. Its sp. gr. is 6·31 at 20·5° C. A product containing molybdenum and silicon in the same proportions was obtained by the reduction of a mixture of molybdenite and silica with calcium carbide.—A. S.

ENGLISH PATENTS.

Di-electric separators. A. J. Boult, London. From H. M. Sutton, W. L. Steele, and E. G. Steele, all of Dallas, Texas. Eng. Pat. 17,653, Aug. 31, 1905.

THE process described consists in separating particles, which need not be electrically conductive or magnetic, by what the inventors term "dielectric hysteretic impedance." The particles fall from the shaking-pan at the end of a hopper on to the circumference of a horizontal cylinder provided with an insulating covering and an outer conducting surface, to which alternating charges are constantly given, by means of a brush, as the cylinder revolves. On one side of the cylinder, and at a short distance from it, there is placed a curved metallic plate or screen, which is either earthed or, preferably, kept supplied with a constant electrostatic charge. Some of the particles which fall between the rotating cylinder and this plate are not influenced by it; their charge at any moment is the same as that of the outer surface of the cylinder, and they leave the latter, under the influence of gravity, at the earliest possible point. Other particles, on the other hand, develop hysteresis in falling through the electrical field; their charge lags behind, and is at any moment opposite to that of the outside of the cylinder, to which they are consequently attracted, and which they leave some distance beyond the non-attracted particles. Electrical devices for obtaining alternating charges of varying periodicity, as well as pulsating charges, are also described in the patent. Certain substances are best separated with certain kinds of charges, *e.g.*, with charges having 2 to 25 alternations per second. &c.—A. G. L.

Electroplating apparatus. W. A. S. Bellson and Co., Ltd., and A. J. Leaver. Fr. Pat. 366,930, June 7, 1906. Under Int. Conv., Jan. 8, 1906.

SEE Eng. Pat. 516 of 1906; this J., 1906, 937.—T. F. B.

Refractory electric furnace; Arrangement of ——. [*Slag heating.*] E. Cornelius and L. Fahn. Fr. Pat. 366,961, June 8, 1906.

IN electric furnaces in which the current traverses a refrac-

tory layer of slag or similar material, which is caused to melt and may be used to transmit heat to other materials, the electrodes are so arranged that the area of their contact with the layer of slag is only a small fraction of the total surface of slag available. In this manner, the greater part of the heat is generated at the surface of contact between the electrodes and the slag. Water-cooled insulators are provided to protect those portions of the electrodes which pass through the wall of the furnace.

Enzyme action; Studies on —— Lipase. II. H. E. Armstrong and E. Ormerod. Roy. Soc. Proc., 1906, B, **78**, 376—385. (See also this J., 1905, 1242.)

THE authors have continued their investigations on the action of ricinus lipase in the form of the air-dried residue obtained after the extraction of the oil from crushed castor seeds by means of ether. This preparation has very little action on ethyl acetate, but gradually hydrolyses the butyrate. The action is stimulated by the addition to the medium of dilute acetic acid up to a certain point. In the hydrolysis of castor oil the maximum effect was obtained when the total concentration of acetic acid was about *N*/17. Other organic acids have a similar influence. Long digestion of the prepared seed, free from oil, with water or dilute acetic acid causes only a very gradual loss of lipolytic activity, but the material loses to a great extent its property of causing oil to emulsify with water. Glycerol has but little action on the activity of the enzyme, at any rate at concentrations up to 25 per cent.; alcohol, on the other hand, is directly inhibitive, and the retardation is approximately proportional to the quantity of alcohol present. The authors formulate the hypothesis that the mechanism of the action involves a direct association of the enzyme with the "carboxylic centre" of the ester, and that this association may be prevented by the hydration of this "centre." Thus, in a given series, the action will be less, the greater the solubility of the ester in water; as a rule, the solubility decreases as the molecular weight of the acid increases. Preliminary experiments with lipase extracts from pig's liver as compared with the lipase of ricinus seeds, indicated that the differences were those of degree only. In experiments with lipase, the heterogeneous nature of the system is an impediment to comparative quantitative measurements. For accurate comparison, it is highly desirable that the substances should be in solution, which is a condition difficult to realise in the case of sparingly soluble esters and natural fats. In the latter case, the lipase extracts from liver show very poor results as compared with ricinus lipase. This is probably due to the impossibility of preparing fine emulsions with the liver extracts, whereas the superiority of the ricinus seed-residue is attributed mainly to its specific property of emulsifying oils.

Lastly, comparative studies on the hydrolysis of the ethylic esters of a series of dicarboxylic acids with a chain of four carbon atoms, *viz.*, succinic, malic, and tartaric acids, showed that the succinate was hydrolysed most readily, whilst the tartrate suffered very little change, the malate occupying an intermediate position. This relation was the same both with liver lipase and ricinus lipase.—J. F. B

Saponification; Theory of ——. J. Marcusson. Ber., 1906, **39**, 3466—3474.

LEWKOWITSCH (this J., 1900, 254) concluded that mono- and diglycerides were formed in the saponification of fats, their presence being indicated by high acetyl values. Since Balbiano (Ber., 1903, 1571; also this J., 1904, 905) has shown that hydroxy-acids, lactones, &c., may be formed during saponification, the author has modified Lewkowitsch's experiments, by diluting the incompletely saponified mass with water, and dividing it into two equal parts, one of which was acidified and acetylated at once, whilst in the other the excess of alkali was neutralised, the soaps separated by the method of Spitz and Hönig, and the residual neutral fat acetylated. In no instance was the anticipated higher acetyl value of the neutral fat obtained; on the contrary, the mixture of neutral fat and free fatty acids in the first portion usually gave the higher results. Lewkowitsch's filtration method was used in each case (this J., 1897, 503). In experiments on similar lines on the partial hydrolysis of olive oil by means of castor seeds, the highest acetyl value of the products was 28·6. The acetyl values of the neutral fat were higher than those of the mixture of neutral fat and fatty acids, yet the highest difference was 9 units; and this the author opines may be due to the presence of hydroxy derivatives or decomposition products of the proteids in the seeds. His experiments on rancid fats gave analogous results, and he therefore concludes that if, as Kremann (this J., 1906, 856) found in his physico-chemical investigations, the hydrolysis of fats does proceed in stages, it is difficult, if not impossible, to isolate the intermediate compounds; and he attributes the high acetyl values observed by Lewkowitsch to alterations of the fatty acids by absorption of oxygen, formation of anhydrides, &c., rather than to the presence of mono- or diglycerides, (See also this J., 1898, 1107; 1899, 1031.)—C. A. M.

Beeswax; Annamese ——. J. Bellier. Ann. Chim. anal. appl., 1906, **11**, 366—368.

THE commercial wax has a variable greyish-yellow colour, and is not homogeneous. It appears to have been kneaded by hand into a suitable consistence for moulding. When melted and strained, it resembles European beeswax in appearance, but differs somewhat, however, from the latter in characters, which are as follows:—Loss at 100° C., 5·02 per cent.; matter insoluble in benzene, 0·5 per cent.; ash, 0·08 per cent. The dried and filtered wax has the following constants:—Sp. gr., 0·964; m. pt., 61° C.; acid value, 7·8; saponific. value, 94·4; iodine value, 6 per cent.; hydrogen evolved at 250° C. with potash and potash-lime, 60·3 c.c. per grm. at 0° C. and 760 mm.; hydrocarbons (unsaponifiable) at 250° C., 10·5 per cent. The above figures for free acid are lower, and those for esters markedly higher than those obtained with European beeswax, and the amount of hydrogen evolved with alkali is also somewhat higher. The characters closely approximate with those of the wax of *Apis dorsata* from British India (this J., 1904, 828).—J. O. B.

Turpentine; Crude ——*from Eastern Asia and from Mexico.* G Weigel. Pharm. Centralh., 1906, **47**, 866.

Eastern Asian turpentine has the usual viscous fluid crystalline consistence, a brownish-yellow colour, and a characteristic odour of pinene. Acid value, 145·45; saponification value, 149·38. On steam distillation it yields 14·5 per cent. of essential oil having $\alpha_D = +39° 9'$.

Mexican turpentine is of horny crystalline consistence, pale lemon-yellow colour, and has a fragrant odour of limonene. Acid value, 107·54; saponification value, 115·12. On distilling with steam it gives 14 per cent. of essential oil, with $\alpha_D = +33° 4'$. —J. O. B.

Pitch and terpenes of the Norway pine and Douglas fir. G. B. Frankforter. J. Amer. Chem. Soc., 1906, **28**, 1467—1472.

THE pitch obtained from the Norway pine, *Pinus resinosa*, by the "boxing process," or from stumps and waste by steam distillation, by slow destructive distillation, and by extraction with various solvents, was examined. By extraction, lean wood yielded 6·2 per cent. of pitch; average wood, 8·6 per cent.; stumps, 19·4 per cent.; pitchy wood, 39·1 per cent., and very pitchy wood, 42·6 per cent. The pitch has the sp. gr. 0·8137 at 20° C.; refractive index at 20°, 1·47869; optical rotation $[\alpha]_D = +4°$. It contains 22·1 per cent. of turpentine, 77·3 per cent. of colophony, and 0·6 per cent. of water. The wood of the Douglas fir or spruce, *Pseudotsuga taxifolia*, yields by extraction from 11·6 to 42·4 per cent. of pitch having the sp. gr. 0·9821 at 20°; refractive index at 20°, 1·51745; and optical rotation $[\alpha]_D = -8·82$. The pitch contains about 22 per cent. of turpentine. On examining the terpenes from the two kinds of wood, it was found that those obtained by destructive distillation of the wood appeared to be of a more complex character than those obtained from the wood and from the pitch by steam distillation, or from the wood by extraction.

Pinene and firpene; Chlor-hydrochlorides of ——. G. B. Frankforter and F. C. Frary. J. Amer. Chem. Soc., 1906, **28**, 1461—1467.

BY the action of hydrochloric acid gas on a chloroform solution of pinene or firpene the corresponding hydrochlorides were obtained. Firpene, $C_{10}H_{16}$, is the terpene from the western fir. It has the following characters:—B. pt., 153° — 153·5° C.; sp. gr. at 20° C., 0·8598; refractive index at 20°, 1·47299; and $[\alpha]_D = -47°·2$. From pinene hydrochloride, the following chlor-hydrochlorides were prepared by the action of hydrochloric acid and potassium permanganate:—Pentachlorhydrochloride, $C_{10}H_{11}Cl_5.HCl$; hexachlorhydrochloride, $C_{10}H_{10}Cl_6.HCl$; and nonachlorhydrochloride, $C_{10}H_7Cl_9.HCl$. Firpene hydrochloride has the same melting point (130°—131° C.) as pinene hydrochloride, but is more volatile than the latter, and more soluble in most of the common solvents. Firpene dichlorhydrochloride, $C_{10}H_{16}Cl_2.HCl$, and hydrobromide, $C_{10}H_{16}.HBr$, were also prepared.—A. S.

India-rubber; Effect of zinc oxide on the vulcanisation and oxidation of ——. R. Ditmar. Gummi-Zeit., 1906, **21**, 103—104.

PERUVIAN rubber was mixed with 4 per cent. of sulphur and rising proportions of zinc oxide, and vulcanised for two hours at six atmospheres, it having been found that milder treatment led to under-vulcanisation. The products were tested as usual. The results show that the strength of the rubber is in general increased by admixtures of zinc oxide, whilst the elasticity is favoured by 1 per cent., but diminishes with larger quantities. Tendency to oxidation is decidedly enhanced by zinc oxide.—W. A. C.

Hides; Apparatus for treating ——. W. Coupe, South Attleboro, Mass. U.S. Pat. 833,443, Oct. 16, 1906.

The apparatus consists of a vat in which a wheel is caused to revolve, and which is intermittently supplied with liquor from a supply-tank communicating with the vat at or near the bottom of the latter. The valve controlling the supply of liquor to the vat is operated automatically by the wheel. At or near the top of the vat is an overflow pipe through which the liquor passes to a receiving tank, wherein it is agitated or stirred, and whence it is pumped back to the supply-tank.—A. S.

Leather; Process of treating —— *with coal tar.* L. H. Francis, Princeton, Cal., Assignor to C. L. Donohoe and F. Freeman, Willow, Cal. U.S. Pat. 834,199, Oct. 23, 1906.

The leather is immersed in a bath of coal-tar, at a temperature of about 110° F., for one to six days, after which it is passed between pressure rollers, then partially dried, and rolled again.—C. S.

French Patent.

Tanning process; Rapid ——. F. Kohl. Fr. Pat. 367,454, June 26, 1906.

See Eng. Pat. 14,602 of 1906; this J., 1906, 941.—T.F.B.

English Patent.

Fertilisers; Manufacture of ——, *and apparatus therefor*; J. Crone, D. C. Taylor, and F. Williams, St. Helens. Eng. Pat. 26,780, Dec. 22, 1905.

Shoddy, hide, leather scraps, and the like are heated in a rotary furnace, as described in Eng. Pat. 5618 of 1905 (this J., 1906, 326), but the quantity of sulphuric acid added is reduced. When the reaction is nearly completed, saturated sodium chloride solution is sprayed over the material; the excess of sulphuric acid is thus converted into sodium sulphate, and the liberated hydrochloric acid is drawn off with the other gases, and passed through the condensing tower. The outlet of the latter discharges the washed gases into the lower part of a filter chamber; at the upper part of this chamber is a perforated plate supporting a layer of peat moss through which the gases pass before being discharged into the atmosphere. About 28 lb. of calcium phosphate, gypsum, or chalk may be added to the material in the furnace before adding the brine, in order to break up any lumps of material which may have formed. The quantity of brine added varies from 0·5 to 0·75 cwt., according to the nature of the raw material.—W. P. S.

French Patents.

Phosphate; Organic limed ——. [*Fertiliser and insecticide*]. Comp. Ind. des Mines et Carrières de Cierp. Fr. Pat. 367,006, June 10, 1906.

The black calcium phosphate of the Pyrenees is mixed with quicklime derived from a pure calcium carbonate, and the mixture is calcined in a furnace with good draught. The product is crushed, screened, and stored in sacks. It is stated to contain from 10 to 20 per cent. of calcium phosphate with from 50 to 70 per cent. of calcium oxide, besides 2 per cent. of graphite, and small proportions of magnesia, alumina, and iron oxide, and to be applicable as a fertiliser and insecticide.—E. S.

Nitrogen compositions [*Fertilisers*]*; Process for producing* ——. O. F. Carlson. Fr. Pat. 367,198, June 16, 1906. Under Int. Conv., Feb. 28, 1906.

See Eng. Pat. 15,445 of 1906; this J., 1906, 858.—T. F. B.

Sugars, higher alcohols, and hydroxy-acids; Action of alkaline copper solutions on the rotatory power of ——. H. Grossmann. Z. Ver. deut. Zuckerind., 1906, 1024—1035.

The author has investigated the influence of alkaline copper solutions on the rotatory powers of a number of optically active organic compounds. The method of procedure was as follows:—Measured quantities of the solutions of known concentration of copper sulphate and of the organic compound were mixed, sodium hydroxide then being added until the precipitate first formed was dissolved. The mixture was made up to 20 c.c., and read in a 20 mm. tube. The source of illumination was a Nernst projection lamp, the light being filtered through Landolt's "bright blue filter." ("hellblau" (*hb*); optical "centre of gravity," 488·5 $\mu\mu$). The following are some of the results obtained: The rotatory power of dextrose was changed from $[\alpha]_{hb} = +78°$ to $-375°$; that of lævulose from $[\alpha]_{hb} = -134·5°$ to $+142·3°$; that of sucrose from $[\alpha]_{hb} = +101·2°$ to $-111·3°$; that of rhamnose from $[\alpha]_{hb} = +12°$ to $-551°$; that of quinic acid from $[\alpha]_{hb} = -61°$ to $+410°$. The above represent the maximum variations observed. The rotatory powers of mannitol, tartaric acid, isosaccharin, and asparagine were unchanged in direction, but much increased in amount. Hence copper must be classed amongst those elements which, as a result of a strong tendency to form complex ions, affect rotatory power to a high degree. Further investigations on the influence of increasing quantities of sodium hydroxide on the rotatory power of copper tartrate showed that in presence of excess of alkali, the strongly dextro-rotatory salt

$$COONa.CHO.CHO.COONa,$$
$$\quad\quad\quad\quad Cu$$

is capable of existence. With increasing dilution, or in the absence of free sodium hydroxide, a lævo-rotatory phase occurs, which is probably represented by the formula—

$$NaO_2C(CHOH)_2CO_2.Cu.O.O_2C(CHOH)_2CO_2Na.$$

This salt suffers further hydrolytic decomposition on greater dilution, and the rotation of neutral sodium tartrate results. The author also shows that by adding sodium hydroxide to ammoniacal copper tartrate solution, a great increase in the rotatory power of the latter is produced. This increase is due to the fact that the copper, which in ammoniacal copper tartrate forms a constituent of the cation, is transferred to the anion on addition

of sodium hydroxide. The following conclusions are drawn from the investigation:—The power of forming intensely coloured alkaline copper solutions, possessed by some organic compounds, is connected with the number of hydroxyl groups present in the latter. The rotatory powers of these solutions is very high, and is often much influenced by the presence of free alkali. Increase of rotatory power, caused by addition of alkaline copper solutions, is, in many cases, accompanied by change of direction of rotation. Amino-compounds, such as asparagine, behave similarly to hydroxyl-compounds. Like copper, chromium also possesses the power of forming coloured complexes of high rotatory power.—L. E.

Sucrose and raffinose in the mother-liquors from the desaccharification of molasses by Steffen's process; K. Andrlík. Z. Zuckerind. Böhm., 1906, 31, 1—6.

It is to be expected that, in the desaccharification of molasses by Steffen's process, a portion of the raffinose will be retained in the mother-liquors. On the assumption that no raffinose is so retained, the author has compiled a table which shows that the accumulation of raffinose in the molasses at the end of a campaign would be much greater than is actually found in practice. Hence it must be assumed that the raffinose does gradually pass into the mother-liquors. The author has proved that such is the case. Three samples of calcium saccharate (obtained by Steffen's process), in the preparation of which, definite degrees of alkalinity towards the end of the precipitation were maintained, were examined. The mother-liquors from these samples were also investigated. With regard to the determination of the proportions of sucrose and raffinose in the mother-liquors, the author found that by the following method, both sugars were precipitated practically quantitatively. The mother-liquor was boiled down, filtered from precipitated saccharate (which amounted to 62—70 per cent. of the whole), the residual saccharate being precipitated with 2 per cent. strontium hydroxide solution and an equal volume of 96 per cent. alcohol. The amounts of sucrose and raffinose in both precipitates were then determined. The results showed that the proportion of raffinose to sucrose in the mother-liquor increased with the alkalinity of the latter. The author concludes that in Steffen's process for the desaccharification of molasses, raffinose is left in the mother-liquors, the amount of raffinose removed in this way increasing with the alkalinity of the liquors. By maintaining a comparatively high degree of alkalinity, a saccharate containing only a small proportion of raffinose is obtained; the loss of sucrose, however, is greater by 2—2½ per cent.—L. E.

Reducing substances and their determination. H. Pellet. XXIII., page 1222.

Proteins of barley: their importance for its valuation and their relations to steeliness. E. Prior. Z. ges. Brauw., 1906, 29, 613—615.

The influence of proteins on barley depends on the forms in which they exist, these being, according to Osborne:—(1) Leucosin, which is soluble in water, together with small quantities of albumoses; (2) edestin, which belongs to the class of globulins, and is insoluble in water but soluble in 10 per cent. salt solution; (3) hordein, which is insoluble in water or salt solution, but dissolves in 75 per cent. alcohol; (4) insoluble proteins, which resist all these solvents. To group (1) belong also certain decomposition products, such as peptones, amides, traces of ammonia, enzymes, &c., and in the embryo and cell nucleus small quantities of nucleins are found. The author's investigations of twenty-one barleys of all kinds lead to the following results:—

	Per cent.	Per cent. of the total protein.
Leucosin	1·39— 2·79	10·49—18·70
Edestin	0·74— 1·79	5·93—12·09
Hordein	1·13— 6·01	10·27—33·02
Insoluble protein	4·47— 8·62	44·70—65·10
Hordein + insoluble protein	6·77—14·55	70·80—80·52

From the curves given, it is seen that no relation exists between the amount of leucosin or edestin and that of the total protein, but as the latter increases, the amount of hordein plus insoluble protein also increases. From the quantity of total protein present, no conclusion can be drawn concerning the quantitative relations of the separate proteins. For the brewing process, hordein and the insoluble proteins alone are of importance, since edestin and leucosin occur mainly in the aleurone grains. It is a general rule that, as the protein content of barley increases, the starch content diminishes, but many exceptions occur to this rule. Steeliness in a barley is due to the cementing of the starch-containing cells by colloidal substances, which may be either nitrogenous or non-nitrogenous. In the latter case, the cementing substance is largely dissolved in the steep water, and a large proportion of the corns hence rendered mealy. But when the starch cells are attached by means of nitrogenous substances, these do not dissolve in water, so that the steeliness persists after steeping. That the transition from the steely to the mealy condition is not due to enzyme action is shown by the fact that water containing chloroform has the same effect as water alone; confirmation of this is given by the observation that the mealiness is increased by treating the barley with 75 per cent. alcohol, which dissolves the nitrogenous substances. Steeping in a vacuum also produces a higher degree of mealiness, the removal of the air from the corns facilitating the access of water to the cementing substance. Hordein is found principally in the neighbourhood of the embryo, of which it forms the first nitrogenous nutriment, whilst the insoluble proteins occur mainly—at any rate in good barleys—in the periphery of the endosperm; only in steely barleys does the layer of insoluble proteins extend towards the middle of the corn.—T. H. P.

Protein constituents of barley. H. Schjerning. Compt. rend. Trav. Laborat. Carlsberg, 1906, 6, 229—307.

The author has investigated the formation and transformation of protein substances during the growth, ripening, and storage of barley. The samples of barley investigated were the following:—I. Two-rowed Prentice barley of the Lyngby type, grown in 1901; the period of development, reckoned from green-ripeness to full maturity—20 days—was very short. II. The same barley as in I., grown in 1903; the period of development—32 days—was rather longer than the average. III. Pure Primus barley, grown in 1905: the period of development—28 days—was approximately normal. Samples from these crops were gathered and examined at various stages of development. The chemical composition of the dry matter of 36 different samples of barley was also investigated. From the results of his work the author has drawn the following conclusions:—(1) Owing to the comparatively great error (about 1 per cent. of protein), which must be allowed for in determining the percentage of protein matter in a barley crop or lot of barley, it is misleading to use this quantity (percentage of protein) as a factor for determining the quality of malting barley. Moreover, the fact that the malting and brewing processes

vary in different localities, renders the valuation of barley according to nitrogen content, somewhat uncertain. (2) Barleys which have had a growth and ripening period of short duration are much more liable to suffer a loss of dry matter by over-ripening than barleys which have had a long period of development. Moreover, with the same species and variety, it appears that the size of the grain depends, to a certain extent, on the duration of the period of development. (3) Barley has acquired full maturity when the conversion of soluble into insoluble carbohydrates, and soluble into insoluble proteins, has ceased, or reached its maximum. (4) When the development of the barley grain—from green-ripeness to yellow-ripeness—takes place during a normal period of development, there exists an absolute equilibrium between the quantity of nitrogen received in a given time and the quantity converted in the same time into insoluble compounds, whereas the transformation of soluble into insoluble nitrogen compounds in a short period of development takes place more quickly than does the intake of nitrogen, the reverse being the case in a long period of development. (5) Condensation of amine-amide compounds into soluble proteins proceeds more quickly during a short than during a long period of development, and this process is very nearly in equilibrium with the further intake of nitrogen as soon as the stage of yellow-ripeness has been reached. (6) The proteoses cannot be supposed to act as intermediate terms in the condensation of amine-amide compounds into proteins of a higher order, but are exclusively to be regarded as hydrolytic cleavage products of higher proteins. (7) An appreciable amount of proteose in a barley crop must always be considered as indicative of rather unfavourable harvest conditions. (8) Provided that barley has properly matured before being reaped, and that it is stored under suitable conditions, a loss of dry matter (respiration loss) is not likely to occur during storage. (9) The ripening barley grain is tending towards a state of equilibrium in respect of its nitrogenous constituents; when, on reaping the barley, this state has been reached, it is not disturbed during storage except in the cases of albumins I. and II. (See this J., 1898, 1191.) (10) The amount of albumin I., in proportion to dry matter, decreases in a greater or less degree according as the barley is allowed to attain a greater and greater degree of maturity, whereas the quantities of albumin II., insoluble nitrogen, total nitrogen, and acidic substances soluble in water, increase more or less. The amount of nitrogenous compounds, soluble in water, is also subject to considerable fluctuations, which, however, are sometimes positive, sometimes negative. Denuclein, proteose, peptone, ammonia, amine-amide, and mineral constituents—in each individual barley sample—show a constant weight in the dry matter, as soon as the corn has reached its full development; consequently, the quantities of these substances remain constant during the real maturation process. (11) Reaped at an early stage, barley is less rich in nitrogen than when reaped later. (12) The chemical composition of dry matter in respect of the various groups of nitrogenous substances, mineral constituents, and acidic substances soluble in water is not dependent on the species, variety, or type of barley. (13) The cultural condition of the soil, as well as climatic conditions, exert some influence on the amount of mineral constituents in the dry matter of barley, and to a certain extent also, upon the amounts of total nitrogen and amine-amide nitrogen, whereas with regard to the other groups of nitrogenous substances, the influence of these factors is less marked than that of the degree of maturity and time of storage.—L. E.

Malt; The nitrogenous constituents of —— which are soluble in cold water and are not coagulated on boiling. H. T. Brown, F. Escombe, A. McMullen, and J. H. Millar. Trans. Guinness Research Lab., 1906, 1, Pt. 2, 167—283.

A PRELIMINARY examination of the aqueous extract of malt "culms" resulted in the identification of asparagine, allantoin, betaine, and choline. Subsequent work on a boiled, cold-water extract of malt showed that in cases of this kind phosphotungstic acid cannot be regarded as a definite group-precipitant. This acid precipitated 51 per cent. of the total nitrogen of the extract, but the actual quantity of the substances precipitated was found to depend on an equilibrium determined by the particular conditions. It is true that the simpler organic bases are found in the precipitate and the amides and amino-acids remain in the filtrate, but the main bulk of the more complex constituents of the extract is divided in a variable manner between the liquid and precipitate. It is shown that the property of evolving nitrogen on treatment with nitrous acid is not confined to the free amino-acids and their amides, but is possessed by the more complicated nitrogenous bodies which contain apparent amino groups of this kind in their complex. Thus the "amino index," *i.e.*, the percentage of the total nitrogen which reacts with nitrous acid as amino-acid nitrogen is used as a specific constant (AoN) of any given nitrogenous complex, and serves as a measure of homogeneity in fractional separations. This constant is analogous to the cupric-reducing constants R and K in the case of carbohydrate complexes. Instead of an aqueous extract of malt, it was found more convenient to continue the work on an extract prepared with 70 per cent. alcohol, with the subsequent extraction of the dry alcoholic extract by water. This "alcohol-water" extract contained about 48 per cent. of the nitrogenous constituents of the boiled, cold-water extract. Part of the difference was made up of albumoses sparingly soluble in alcohol, whilst the rest remains uninvestigated. The alcohol-water extract yielded asparagine, tyrosine, leucine, and allantoin, not precipitated by phosphotungstic acid, whilst betaine and choline were isolated from the precipitate. Practically the whole of the amides and amino-acids were eliminated from the extract by fermentation with large quantities of yeast, under conditions which restricted reproduction. The residual liquid was then saturated with ammonium sulphate, which threw out malt albumoses, and separated into fractions I. and II. by means of 84 per cent. alcohol. The ammonia remaining after evaporation and the organic bases were next precipitated as platinochlorides. Further "salting out" of the solution with zinc sulphate then yielded a malt-albumose III. From the filtrate from this, phosphotungstic acid precipitated most of the malt-peptones, some, however, remaining unprecipitated, as the result of equilibrium, together with a little leucine which had escaped assimilation by the yeast. The malt-peptone fraction was separated into peptones I. and II., according to the relative solubilities of their phosphotungstic compounds. The malt albumoses and malt-peptones differ from the similar derivatives of other proteins in the fact that they give no biuret reaction, and are not precipitated by iron ammonium alum. The malt-albumose I. possesses the property of producing a persistent froth in aqueous solutions. The composition of the uncoagulable nitrogenous cold-water extract of malt is estimated to be as follows, the results being expressed as nitrogen per cent. of the total nitrogen:—Ammonia, 3·5; malt-albumoses, 20; malt-peptones, 31; amides and amino-acids, 8·5; organic bases, 4·0; balance (uninvestigated), soluble in water but insoluble in 70 per cent. alcohol, 33 per cent. The albumoses and peptones are probably the conversion-products of the alcohol-soluble protein of barley, the hydrolysis of which, whether by enzymes or acids, results in the production of bodies of similar character to those studied. This hydrolysis takes place with the progressive elimination of part of the amide nitrogen as ammonia and of the amino-nitrogen as free amino-acids, with a corresponding accumulation of the basic nucleus in the products.—J. F. B.

Barley; Culture of excised embryos of —— on nutrient media containing nitrogen in different forms. H. T. Brown, F. Escombe, A. McMullen, and J. H. Millar. Trans. Guinness Research Lab., 1906, 1, Pt. 2, 288—299.

THIS investigation was undertaken in order to differentiate to some extent between the "down-grade" (katabolic) products of the nitrogenous reserves of the endosperm, and the "up-grade" (anabolic) nitrogenous bodies directly convertible by the growing embryo into living

tissue. For this purpose, excised embryos of barley corns were grown on porous plates saturated with a nutrient solution containing non-nitrogenous salts and cane sugar. To this solution were added, in separate experiments, equal quantities of nitrogen in a large number of different forms, and the availability of these nitrogenous compounds as nutrients was measured: (*a*), by the increase in weight of the dried plants, and (*b*), by the increase in the quantity of nitrogen they contained. By comparing the nitrogen results with those of a control experiment in which no nitrogen was added, a ratio was obtained expressing the "specific nitrogen assimilation" for each particular substance. In this way the quantity of nitrogen in the control plants being 1·0, the specific assimilation of tyrosine was 0·57 and of phenylalanine 0·87, showing that these bodies exert a definitely poisonous influence. The assimilation value of leucine was 1·14, but since the dry weight of the plants fell short of that of the control plants, it must be concluded that leucine also has an inhibitive effect. A result of a similar order was obtained with a crude mixture of "down-grade" products from malt, consisting mainly of malt peptones and albumoses, together with some "unclassified bodies"; here also the development of the plants was retarded, although the nitrogen assimilation was 1·18. The other substances tested showed both an increased development of dry substance and higher nitrogen ratios when compared with the results of the control plants, *viz.*, choline, 1·46; allantoin, 1·49; betaine, 1·50; ammonium sulphate, 1·64; aspartic acid, 1·84; glutamic acid, 1·95; potassium nitrate, 2·18; asparagine, 2·70. Although asparagine is the "up-grade," nitrogenous nutrient *par excellence*, the plants grown on artificial asparagine-cane sugar media are never so vigorous as those grown on their natural endosperms, in spite of an increased nitrogen assimilation amounting under the best conditions to 50 per cent. This is probably due to a defect of the cane sugar as the carbohydrate nutrient, which, although the best artificial nutrient known, is inferior to the natural material and thus becomes the limiting factor of the growth.—J. F. B.

Barley and malt; The water-soluble polysaccharides of ——. H. T. Brown, F. Escombe, A. McMullen, and J. H. Millar. Trans. Guinness Research Lab., 1906, 1, Pt. 2, 312—337.

THE authors have begun a thorough re-investigation of the soluble gummy carbohydrates which exist in barley, and to which O'Sullivan gave the names of α- and β-amylans. The best way of separating these is to make a full conversion of the raw grain by means of an extract of kilned malt at a temperature of 50°—55° C. On the addition of alcohol of a certain strength to the filtered wort, the amylans are precipitated, whilst the conversion dextrins remain in solution. The quantity of crude amylan thus obtained amounted to 9—10 per cent. of the dry weight of the barley. When freed from nitrogenous matters the amylans gave a viscous, opalescent solution with water, possessing no cupric-reducing power, and $[\alpha]_D = +31·6°$. The rotatory powers of different preparations, however, varied considerably. The substance is readily soluble, and gives clear solutions when potash is added to the water, but the presence of potash influences the rotatory power. After hydrolysis for 24 hours by oxalic acid, it was found that the solutions contained quantities of *r*-tartaric acid, amounting to 10 per cent. of the original amylan. This acid is formed by the action of oxalic acid on pentose sugars, the primary products of the hydrolysis. Dextrose was the only fermentable sugar present in the solution. The amount of dextrose disappearing on fermentation corresponded to 60—70 per cent. of the original amylan. Of the unfermentable residue, about one-fifth consisted of pentoses, both arabinose and xylose, and the remainder of an unknown body with low cupric-reducing power and low rotatory power. Determinations of the percentage of amylans and starch at different periods of the development of the corns showed no genetic connection between the two, and their formation is apparently independent. Laevorotatory amylans can be extracted from barley by the joint action of diastase and yeast. The amylan precipitated by alcohol from the unfermentable residue was far less viscous in solution and less gummy in character than the ordinary amylan of barley. It possessed $[\alpha]_D = -100·34°$, and yielded ordinary arabinose on hydrolysis. This amylan is considered to be identical with the araban isolated from malt by Wroblewski (this J., 1897, 1031). Malt, when treated for the isolation of the amylans, yielded very much smaller quantities than the raw barley from which it was made. The product, about 3 per cent., possessed similar properties to those of barley amylan, but with a considerably higher dextrorotation, $[\alpha]_D = 118°$, and yielded dextrose on hydrolysis. —J. F. B.

Malting process; Migration of nitrogen from the endosperm to the embryo during the ——. H. T. Brown, F. Escombe, A. McMullen, and J. H. Millar. Trans. Guinness Research Lab., 1906, 1, Pt. 2, 284—287.

WHEN the embryo of the barley corn is excised and is allowed to grow in water or in carbohydrate media, the restricted development of the root and the early appearance of signs of starvation suggest that the embryo is suffering from the absence of nitrogenous nutrition which, under normal conditions, it would obtain from the endosperm. This migration of nitrogenous compounds from the endosperm to the embryo during germination was confirmed by the analysis, at intervals of two days, of 100 corns each time, taken from the same lot of barley during the malting process. The corns were dissected, and the nitrogen was determined separately in the endosperms, in the embryos deprived of their rootlets, and in the rootlets alone. In this way a gradual and continuous decrease of the nitrogen in the endosperms was observed side by side with a corresponding increase of the nitrogen in the embryos and rootlets, until, after 9 days' germination, about 35 per cent. of the nitrogen originally present in the endosperm had migrated to the embryo. A very considerable proportion of this nitrogen must have been converted from the form of insoluble protein into soluble and diffusible compounds before the migration could take place.—J. F. B.

Yeast-juice; Alcoholic ferment of —— II. The co-ferment of yeast-juice. A. Harden and W. J. Young. Roy. Soc. Proc., 1906, B., 78, 369—374.

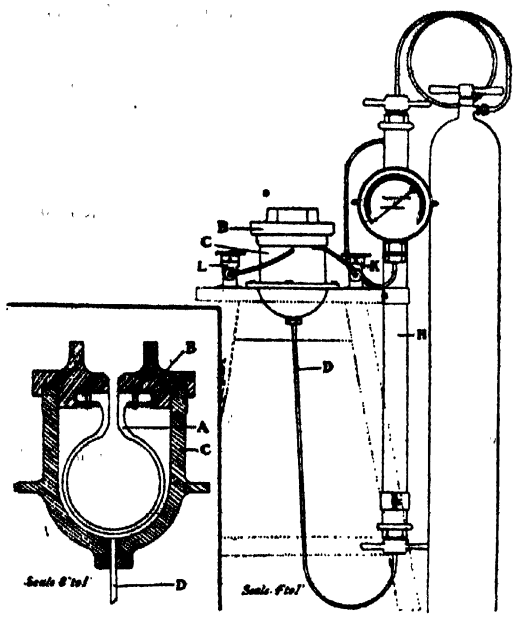
IN the first paper (this J., 1906, 490) it was shown that yeast-juice could be separated by filtration through a Martin gelatin filter into two portions, both of which are incapable of fermenting dextrose by themselves, whereas a mixture of the two produces a vigorous fermentation. The inactive residue which does not pass through the filter may be regarded provisionally as the ferment, whilst the filtrate may be called the "co-ferment." The complete removal of the co-ferment is not generally effected by a single filtration, but if the residue be re-dissolved and again submitted to the treatment, it can be obtained in a condition in which it is perfectly inactive towards dextrose by itself. This inactive residue, when dried *in vacuo*, retains its potential fermentative properties for a considerable time. When a small quantity of boiled yeast-juice is added to a solution of the inactive residue in presence of dextrose, fermentation proceeds until the quantity of co-ferment added with the boiled juice is exhausted; a further addition of boiled juice then induces a second fermentation, and so on until the original quantity of ferment is exhausted. Cessation of fermentation may be due to the disappearance either of the ferment or of the co-ferment, according to the relative amounts of each originally present. The authors have studied the rate of the disappearance of the co-ferment from yeast-juice as the result of autolysis. This disappearance takes place in about 48 hours at a temperature of 26° C., but in presence of dextrose a small quantity still exists after 4 days; the ferment remains active, and its presence can be observed by the addition of fresh boiled juice to the autolysed juice. Lastly, the authors show that the addition of soluble mineral phosphates to the solution of the inactive residue cannot supply the place of the co-ferment; the latter, therefore, does not consist of phosphates precipitable by magnesium mixture. This is confirmed by the fact that autolysed juice, which can

tains large quantities of phosphates in the precipitable condition, is devoid of co-fermentative properties.
—J. F. B.

Lactic acid bacteria; Vitality and fermentative capacity of industrial ——. C. Wehmer. Chem.-Zeit., 1906, **30**, 1033—1035.

ALTHOUGH it is generally supposed that the purely vegetative forms of bacteria are possessed of but little vitality in the dry state, the author shows that this is not always the case. He has studied a non-sporulating species of industrial lactic acid bacterium, possessing a maximum acid-producing power at a temperature of 40° C. The culture was preserved in the same flask in which it had carried out its fermentation. In the course of time the bacteria had dried down on the surface of the crystalline calcium lactate which they had produced. Under these conditions the vitality of the bacteria was quite unimpaired after 5 years; after 6 years, however, it was necessary to sow larger quantities of the deposit in order to find living cells, and after 10 years the whole culture was apparently dead. This great vitality of vegetative bacteria cells, almost equal to that of anthrax spores, was only exhibited when the cultures were allowed to ferment in presence of chalk. When the acid produced in the fermentation was not neutralised, the cultures died in 6—10 weeks. Determinations of the fermentative power of this species, in presence of chalk, showed that in a solution containing 15 grms. of dextrose, 10·5 grms. of lactic acid were produced, and that at the end of that time the dry weight of the bacteria was 20 mgrms., equivalent to 100 mgrms. living weight. This is a production of 100 times the weight of the bacteria, or at the rate of 10 times their weight per day. Although dextrose should yield theoretically an equal weight of lactic acid, this result is never attained, even under the best conditions; 90—91 per cent. of lactic acid, calculated on the dextrose, is the highest yield which is ever obtained, and, under industrial conditions, a yield of 60—70 per cent. is usual. In practice it is necessary to choose between losses by incomplete fermentation and losses by infective fermentation, the danger of which increases with the time. The completeness of the fermentation depends largely on the completeness of the saccharification of the mash. Butyric ferments, moulds, and even yeasts enter into competition with the lactic bacteria, and the calcium lactate which is already formed may itself be consumed in the later stages of fermentation by other organisms. When all accidental sources of loss have been eliminated, there still remains a quantity of sugar disappearing from the medium, but not converted into lactic acid, which is greater in this kind of fermentation than in others; the manner in which this sugar is consumed is, however, still undetermined.—J. F. B.

Enzymatic action of the radish (Raphanus sativus, L.). T. Saiki. Z. physiol. Chem., 1906, **48**, 469—472. Chem. Centr., 1906, **2**, 1275—1276.



THE author has detected in radishes a very powerful diastatic ferment. *Daucas carota* and *Brassica carota* also contain a diastase, but this is less active than that of the radish. No evidence could be obtained of the presence of a proteolytic, a lipolytic, or an alcohol-forming ferment in radishes. Among the reducing substances formed on treating the expressed juice of the radish with a freshly-prepared paste of purified wheat starch, maltose was detected. After four hours at 40° C., 83·3 to 91·6 per cent. of the starch was saccharified, the reducing substances being calculated as maltose. The diastase prepared from radishes according to the usual method formed a yellowish-white, moderately hygroscopic powder.
—A. S.

Sugar; Fermentation of —— without enzymes. H. Schade. Z. physik. Chem., 1906, **57**, 1—46.

THE decomposition of dextrose by alkalis under various conditions is attended by the production of an intense brown coloration, and the possible formation of an immense number of products, some simple and some more or less uncharacterised. But the author has found that if the decomposition be carried out in presence of hydrogen peroxide, it takes place without the slightest browning, so long as the peroxide is in excess. The author explains this by the fact that acetaldehyde is one of the main primary products of the decomposition, and that the brown-coloured complex products are the result of secondary resinification of the aldehyde. Any agent which combines with the aldehyde prevents the brown coloration, the most efficient being hydrogen peroxide, which oxidises it to acetic acid, and sulphites or cyanides, which fix it by combination. The removal of the volatile aldehyde by the rapid passage of a current of gas is also efficient up to a certain point. Under certain conditions, *viz.*, 2 grms. of dextrose, 4 grms. of caustic potash, and 200 c.c. of water, digested for 8 days at 40° C., with the passage of a rapid current of air, a quantitative yield of formic acid in the ratio of 2 mols. of acid to 1 mol. of dextrose is obtained. With lævulose at similar concentrations, but at a temperature of 15°—18° C., and with the addition of hydrogen peroxide, an additional proportion of 2 mols. of acetic acid is also produced, owing to the oxidation of the acetaldehyde *in situ*. The decomposition of any monose sugar by alkali, when the solution remains colourless, is therefore represented by the equation: $C_6H_{12}O_6 = 2CH_3CHO + 2HCOOH$, with only traces of other products; this decomposition proceeds at different velocities with different monoses. It was to be expected that an equimolecular mixture of acetaldehyde and formic acid would be convertible into alcohol and carbon dioxide. This transformation was in fact brought about by the catalytic action of spongy rhodium. A 5 per cent. solution of sodium formate, slightly acidified with acetic acid, was treated with spongy rhodium and gradually heated under a reflux condenser to 60° C. At the same time an equivalent quantity of acetaldehyde was distilled into the liquid, the vapours being caused to enter at the bottom of the vessel. An evolution of carbon dioxide then took place, and ethyl alcohol was recovered from the liquid, with a yield of 60—70 per cent. of the theoretical. Thus, in two stages of purely chemical reaction, the sugar had been converted qualitatively and quantitatively into the same products as are obtained in fermentation by yeast. The splitting up of the sugar into aldehyde and formic acid is a typical catalytic phenomenon taking place under the influence of hydroxyl ions, since equivalent quantities of caustic soda and potash decompose the same amount of sugar in the same time; thus both stages are spontaneous breakdowns. The author postulates two ways in which the sugar molecule can break down, *viz.*: the aldehyde and the acid breakdown. These are analogous to the two typical decompositions, ketonic and acidic, of ethyl acetoacetate. A third way is left unformulated to account for the complex decompositions which ensue under less regulated conditions. The general tendency is vastly in favour of the aldehydic breakdown described above, but with higher concentrations of hydroxyl ions the acidic breakdown, with production of lactic acid, becomes predominant. Lastly, the author discusses the analogies between the various biological breakdowns of sugar, *viz.*, alcoholic, lactic, acetic, and formic fermentations, and his purely chemical decompositions, and shows that they are all variations or special cases of one and the same phenomenon, *viz.*, migrations and rearrangements of the hydrogen and hydroxyl ions of the labile carbohydrate molecule, with or without secondary oxidation.—J. F. B.

Nitrogenous constituents from malt extract, by porcelain filtration; Separation of ——. H. T. Brown, F. Escombe, A. McMullen, and J. H. Millar. Trans. Guinness Research Lab., 1906, **1**, 306—311.

A SPECIAL form of porous porcelain filter is described (see figure). The apparatus consists of a porcelain filtering bulb, A, which is porous only in the lower half; this bulb is fitted to a bronze lid, B, which is screwed into the containing vessel, C. The liquid to be filtered is placed in the cylinder, H, and is forced by means of carbon dioxide under pressure into the bottom of the vessel, C, by way of the tube, D. Filtration through the lower half of the porcelain bulb then takes place under the pressure of the gas, the filtrate being withdrawn from inside the bulb by an aspirator tube. The pressure can be released by the

valves, K and L. This apparatus has been used for the removal of complex nitrogenous matters from a state of colloidal solution. The degree of fractionation obtained was measured by determination of the "amino-index" of the filtrate (see page 1110) as compared with that of the original liquid, the complexity of the compounds being inversely proportional to the "amino-index." It was found that the efficiency of the removal of the complex colloids depended to a very large extent on the clogging of the pores of the filter, and that a second filtration yielded better results than the first.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 1064.)

(*A.*)—FOODS.

Formaldehyde; Presence of —— [in certain foods. G. Perrier. Compt. rend., 1906, 143, 600—603.

THE author has examined, for formaldehyde, ciders made from apples sterilised according to his proposals (this J., 1905, 537). Trillat's method gave negative results, but the more delicate method of Voisenet (this J., 1905, 1326) showed that most of the samples contained from 1/500,000th to 1/300,000th of formaldehyde. The proved occurrence of formaldehyde in the air, and in products of combustion, especially wood-smoke, led the author to examine a number of smoked foods—bacon, ham, sausages, herrings, &c.—in all of which he found quantities of formaldehyde, varying from 1/3,000,000th to 1/40,000th. Strict administration of the law prohibiting the presence of formaldehyde would preclude the use of these articles of food; and the author contends in favour of an alteration in the law, with prescription of allowance up to a maximum limit, instead of prohibition.—J. T. D.

ENGLISH PATENTS.

Proteids from ground-[earth-] nuts; Preparation of ——. W. M. Williams, Harlesden, Middlesex. Eng. Pat. 17,116, July 30, 1906.

THE earth-nuts (*Arachis hypogæa*), are decorticated, as much as possible of the oil is removed, and the residue reduced to a fine meal. This meal is then extracted with a 15 per cent. sodium chloride solution, using about 1 gall. for each 0·75 lb. of meal; the mixture is stirred frequently for one hour, and filtered through cloth of very fine texture. The proteids in the filtrate are then precipitated by saturating the solution with carbon dioxide under pressure, or by the addition of successive small quantities of dilute hydrochloric acid, with or without previous treatment with carbon dioxide, using the minimum of acid required for a distinct precipitation at each operation. The proteids obtained are washed with water saturated with carbon dioxide, and re-dissolved in ammonium carbonate solution. If desired, the paste may be dried in thin sheets or layers, or forced through small holes in a plate, and dried in the form of threads. The product may be mixed with other foods, such as flour, meat preparations, &c.—W. P. S.

Centrifugal separators for cream and other liquids. C. G. P. De Laval and E. E. F. Fagerström, Stockholm. Eng. Pat. 18,708, Aug. 21, 1906.

ANNULAR flanges are placed on the wall of the separator drum opposite to partition plates extending from the central feed-pipe nearly to the wall of the drum. The flanges project inwardly towards the edges of the plates, and cause any sediment in the liquid to be deposited in annular chambers formed below and above the flanges. Obstruction of the openings between the plates and the flanges is thus prevented.—W. P. S.

FRENCH PATENTS.

Milk and other liquids containing proteids; Process for the desiccation of ——. J. R. Hatmaker. Fr. Pat. 366,751, June 1, 1906.

MILK, or solutions of eggs, blood, and the like, are dried on rotating rollers heated to a high temperature; the liquid is not in contact with the roller for more than two seconds, and the dry film is removed by means of a scraper. If desired, the operation may be carried out under reduced pressure. The dry products obtained are also claimed.—W. P. S.

Butter; Process of making artificial ——. D. Müller, J. Gottlieb, and A. Meisels. Fr. Pat. 366,766, June 1, 1906.

SEE Eng. Pat. 12,916 of 1906; this J., 1906, 903.—T. F. B.

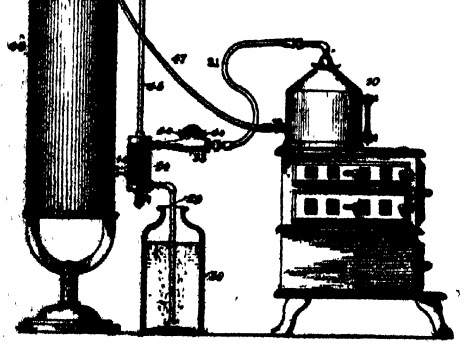
Flour, grain, rice, and other substances; Process and apparatus for the electrical purification of ——. J. L. Lawson. Fr. Pat. 367,596, July 2, 1906. Under Int. Conv., July 6, 1905.

SEE Eng. Pat. 13,909 of 1906; this J., 1906, 921.—T. F. B.

(*B.*)—SANITATION; WATER PURIFICATION.

English Patents.

Water, sewage effluent, and the like; Process for the purification of ——. P. Kestner, Lille, France. Eng. Pat. 20,750, Oct. 13, 1905.



The water, with or without the addition of an antiseptic agent, is sprayed on to a centrifugal fan having a large number of blades placed close together, or preferably, into the open end of an atomising drum such as is described in Eng. Pat. 20,697 of 1905 (this J., 1906, 915). The fan, or drum, is rotated at a high speed, and a current of air is forced in so as to be mixed intimately with the atomised water.—W. P. S.

Water and other liquids; Apparatus for purifying [electrolytically] ——. G. W. J. Allen, Bristol. Eng. Pat. 9002, April 14, 1906.

The water is passed through a narrow earthenware channel, in which it is repeatedly electrolysed by means of electrodes placed in pairs across the channel. The electrodes consist of platinum wire gauze, and each pair is connected with a separate trembling coil. Between the electrodes, the bottom of the channel is slightly depressed so as to form a hollow in which some water will always remain to make electrical connection between the poles of each pair. To prevent the coils becoming over-heated through continuous working, an automatic contact-breaker is provided, consisting of a rotating shaft on which are placed a number of metallic arms corresponding with the number of coils in use. The rotation of the shaft causes the arms to dip consecutively into mercury troughs, and, the necessary conducting wires being provided, allows the current to pass through the separate coils. The arms are so arranged on the shaft that one coil is cut off while the other two are in connection with the battery, and so on. The shaft is rotated at a suitable speed by a small motor, or other device, and means are also provided for cutting out the contact-breaker, and connecting the coils directly with the battery. —W. P. S.

United States Patent.

[Water] Distilling apparatus. G. F. Wentz, St. Louis, Mo. U.S. Pat. 833,271, Oct. 16, 1906.

A still or generator, 10, heated in any suitable manner, has a vapour-pipe, 31, leading to the condensing coil, 24, which is provided with an injector, 38, to draw in air through the capped opening, 40. The air and vapour pass through the coil where the latter is condensed, and liquid and air pass to the receiver, 30, by the pipe, 29, which dips into the liquid, as shown, so that the escaping air is compelled to bubble through the condensed liquid. The condenser is connected to the water store tank, 43, by the pipes, 44 and 45, and the still is fed by the pipe, 47, with water from 43. The capped air inlet, 40, is so arranged that the supply of air can be regulated by screwing down the cap over a perforated nipple, and the air may be filtered, if desired, through porous material placed in the cap.—W. H. C.

French Patents.

Effluents; Apparatus for filtering and purifying works and other ——. G. Dünkelberg. Fr. Pat. 366,991, June 8, 1906. Under Int. Conv., June 6, 1906.

See Ger. Pat. 165,414 of 1904; this J., 1906, 492.—T. F. B.

Sewage and waste waters; Apparatus for the bacterial purification of ——. A. Gilson. Fr. Pat. 366,974, June 9, 1906.

The process and apparatus provide for the anaërobic and aërobic treatment of sewage and the like, the latter being conducted to the bottom of a vessel, which is closed to the air, and consists of several concentric chambers connected with each other alternately at the top and bottom. After passing through a further series of rectangular closed vessels, the sewage enters the aërobic part of the plant, which consists of a number of compartments filled with porous and other materials, and connected with each other by means of automatically acting siphons. Traps are provided to prevent the admission of air to the anaërobic parts of the plant, whilst air-supply pipes are fitted to the aërobic compartments.—W. P. S.

French Patent.

Phosphate; Organic limed ——. [*Fertiliser and Insecticide.*] Comp. Ind. des Mines et Carrières de Cièrp. Fr. Pat. 367,006, June 10, 1906. XV., page 1108.

XIX.—PAPER, PASTEBOARD, &c.

(*Continued from page* 1064.)

Bamboo and Pousolsia [for papermaking]. Kaindler. Monit. Pap. Franç.; through Paper Making, 1906, **25**, 522—523.

The possibilities of bamboo as a paper-making material are well known; it closely resembles straw in character, with a slight advantage from the point of view of quality. Its use for paper-making is limited, first, by the fact that it has a considerable value for other purposes, and, secondly, because in order to get good results the plants must be converted into pulp whilst still in the green state. Pousolsia (*Memorialis pentandra*) is a member of the nettle family which grows in India, but has not yet been cultivated for exportation. The isolated bast fibre is extremely long and wide; it easily attains a length of 750 mm. It possesses the peculiarity of splitting up longitudinally into fine fibrillæ, with a minimum amount of mechanical treatment. This property would be extremely valuable for the preparation of strong white papers of even texture and smooth surface. The fibres in present use, *viz.*, flax and hemp, which are capable of giving these fibrillæ, require such prolonged beating to produce this effect that the paper acquires a greyish appearance. The cleaned bast of Pousolsia requires only a very slight chemical treatment with caustic soda and "bleach" to convert it into a pure white pulp of the best quality; it is stated that several crops a year could be obtained without special care in the cultivation.—J. F. B.

Paper industry of Russia. Bd. of Trade J., Nov. 1, 1906. [T.R.]

The demand for paper in Russia is still very small; it is mostly satisfied by Russian paper mills, of which there are 98, the production being 1,300,000 metric quintals (1 met. quintal = 100 kilos.). Finland is the chief "foreign" purveyor of paper, turning out 516,000 quin-

tals. Finland supplies mostly common sorts and newspaper paper, which is cheaper than Russian, in spite of Customs duties and other expenses on delivery into Russia. This is due to the abundant and inexpensive motive power and vast resources of material, necessary in the manufacture of paper, of which Finland disposes. Of Russian firms, only one successfully competes with Finland in the commoner sorts of paper, due to this mill having free water power at its disposal. Russia is becoming more dependent on her own resources for supplies of certain kinds of paper and of material for its manufacture. Imports of rags from Germany have declined, and exports of them from Russia to Germany have increased. Decreases are also shown in the imports of paper pulp, cellulose, and wall papers.

ENGLISH PATENT.

Waste sand from glass-works, commonly known as burgy; Treatment and utilisation of —— [*as filling material for linoleum, leather, paper, &c.*]. W. Thompson. Eng. Pat. 26,893, Dec. 23, 1905. VIII., page 1096.

UNITED STATES PATENTS.

Degumming fibrous plants; Process for ——. C. Colahan, Chicago. U.S. Pat. 833,507, Oct. 16, 1906.

FIBROUS plants are degummed by heating with the waste products of petroleum or other mineral oil refineries, steam being injected during the process; the fibres, thus thoroughly freed from mucinous substances, are dried in the open, and subjected to a "braking" action to remove the "hurds."—T. F. B.

Wood pulp; Manufacture of chemical or sulphite ——. R. Roe, jun., Niagara, Wis. U.S. Pat. 833,750, Oct. 23, 1906.

UNSEASONED or wet wood is cut up into chips, which are then dried artificially, subsequently being digested with an acid liquor under steam pressure.—J. F. B.

Sulphite liquor; Treating waste ——, *and* [*adhesive*] *compound obtained* [*therefrom*]. J. S. Robeson, Camden, N.J. U.S. Pat. 833,634, Oct. 16, 1906.

WASTE sulphite liquor from the digestion of spruce wood is neutralised by milk of lime, and concentrated *in vacuo* to a density of about 30° B. to form an adhesive product, soluble in water, clear or translucent, and in strong solution not precipitating glue solution.—E. S.

[*Wood pulp*] *Sulphite process; Recovery of valuable gases in the* ——. E. Morterud, Christiania, Norway. U.S. Pat. 833,936, Oct. 23, 1906.

IN the manufacture of sulphite wood pulp, the liquid and gaseous contents of the digester are discharged, after boiling, into a closed chamber in which a low pressure (about or below atmospheric pressure) is maintained. The gases and steam collected in this chamber are passed through a closed apparatus where they come in contact with water of such a temperature that the vapours are condensed without an appreciable absorption of the gases. The heated liquid is then cooled, and used again for condensing the vapours of a subsequent charge. The uncondensed gases are passed on to a chamber in which they are absorbed and utilised for the production of fresh digesting liquor.—J. F. B.

Resin soap; Process for emulsifying —— *in water*. M. Erfurt, Straupitz, Germany. Re-issue No. 12,549, dated Oct. 23, 1906, of U.S. Pat. 781,506, Jan. 31, 1905.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 1067.)

Calumba [*Columba*] *root; Alkaloids of* ——. J. Gadamer. Chem.-Zeit., 1906, **30**, 924.

BESIDES amorphous alkaloids, calumba root contains considerable quantities of two crystallisable alkaloids, and a small amount of a third. After extracting the root with alcohol, treating the extract with water, and separating gummy and resinous matters, the alkaloids are precipitated with potassium iodide, and the iodides separated by a laborious fractional solution, and crystallisation from alcohol. The most soluble, for which the name *jateorrhizine* is proposed, has been investigated by Feist, and has the formula $C_{20}H_{20}NO_5.OH$; the second is Günzel's *columbamine*, $C_{21}H_{22}NO_5.OH$; and the least soluble is called by the author *palmatine*—its formula is probably $C_{22}H_{24}NO_5.OH$, but it has as yet been obtained in such small quantity that this is not certainly established. —J. T. D.

Hordenine. G. O. Gaebel. Arch. Pharm., 1906, **244**, 435—441.

WHEN hordenine, the base isolated from malt culms by Léger, to which the empirical formula $C_{10}H_{15}NO$ has been given, is methylated, and oxidised with alkaline permanganate, it yields anisic acid. Since the base is optically inactive, and when methylated and subsequently decomposed, yields trimethylamine, it must have the constitution. (1)HO.C_6H_4.CH_2.$CH_2N(CH_3)_2$(4).—J. O. B.

Peppermint oil; Russian ——. J. Schindelmeiser. Apoth-Zeit., 1906, **21**, 927—928.

THE oil, distilled from plants cultivated in the Province of Tambow, had the sp. gr. 0·908 at 19° C.; α_D = —19°45'; b.pt. 200°—255° C.; solubility in 70 per cent. alcohol 1:4, in 95 per cent. alcohol, 2:1. It solidified on long exposure in a mixture of ice and salt. It contained 16·36 per cent. of menthone, 51·22 per cent. of free menthol, and 4·8 per cent. of menthyl esters, calculated as acetic ester; but valeric acid was present as well as acetic acid in these esters. Pinene, *l*- and *d*-limonene, cineol, and a sesquiterpene were also present. No phellandrene, which occurs in American peppermint oil, and no menthene, as recorded by Andrejeff and Andres as occurring in Russian oil, were found.—J. O. B.

Myrrh; Essential oil of ——. K. Gorter. Arch. Pharm., 1906, **244**, 412—435.

CUMINALDEHYDE was isolated, to the extent of 1 per cent., from three of the four specimens of oil examined. Eugenol and a small trace of *m*-cresol was present in all four oils. Old myrrh oil has an acid reaction, due to the presence of free acetic and palmitic acids. In the freshly distilled oils these acids exist as esters. A resin was isolated from old oils by shaking out with light petroleum spirit. On reducing this with sodium and amyl alcohol, a hydrocarbon was obtained, which gave a crystalline hydrochloride, probably cadinene dihydrochloride. On fractionating over sodium, several terpenes were obtained; pinene, dipentene, and limonene were identified, and a fourth body with the same formula, belonging to the limonene group, was isolated. This had the optical rotation α_D = + 80°, and afforded a crystalline tetrabromide and hydrochloride. It is not certain whether the dipentene originally occurs as such, or is formed from the limonene, and whether, as is probable, the new terpene may be an intermediate product between limonene and

dipentene. Two sesquiterpenes, one with the sp. gr. 0·926, b.pt. 163° under 12 mm., the other with the sp. gr. 0·911, b. pt. 151° under 15 mm., were isolated, and could not be definitely identified with the known sesquiterpenes. The sesquiterpene which forms a well-crystallised hydrochloride is closely related to, or identical with cadinene. —J. O. B.

Carbon diselenide. A. von Bartal. Chem.-Zeit., 1906, **30**, 1044—1045.

SUPERHEATED steam is passed through a tube containing phosphorus pentaselenide at a low red heat, and the liberated hydrogen selenide is conveyed into a flask charged with a nearly saturated solution of cadmium sulphate at 70°—80° C., a deposit of reddish-brown flakes of cadmium selenide being produced. The precipitate is filtered, washed with water until the washings cease to give a turbidity with barium chloride, and then dried for several hours at 130°—140° C. This product is mixed with asbestos, and placed in a bulb tube connected with a flask containing about 150 c.c. of carbon tetrachloride and with a Liebig condenser, the receiver of which is cooled with ice-water. The tetrachloride flask is warmed on the water-bath, and the liberated vapour is passed through the bulb heated to low redness, this operation being repeated twelve times with the liquid collected in the receiver. The final distillate is fractionated on the water-bath; the bulk passes over at 79°—80° C., and consists mainly of carbon tetrachloride. The fraction, 80°—90° C. (a red, somewhat fuming distillate), after being diluted with water and boiled under a reflux condenser to decompose selenium chloride, is filtered and redistilled, furnishing at 78°—90° C., a greenish-brown liquid, smelling like carbon bisulphide. Treated with a concentrated solution of caustic potash in absolute alcohol, added drop by drop, this liquid deposits dark, orange-yellow needles of potassium selenoxanthate, thus demonstrating the possibility of producing carbon diselenide by the above process. The operation is, however, difficult, and the product is extremely unstable. Carbon oxyselenide, or an analogous product, can be prepared by passing phosgene over cadmium selenide at red heat, and cooling the gaseous product with ice water and a mixture of solid carbon dioxide and alcohol in succession. The gas burns with the characteristic blue flame, and gives an abundant deposit of selenium.—C. S.

Citral in lemon oils and extracts; Method for the determination of ——. E. McK. Chace. J. Amer. Chem. Soc., 1906, **28**, 1472—1476.

THE author has applied the magenta-sulphurous acid reaction of aldehydes (see this J., 1897, 265) to the colorimetric determination of citral in lemon oils and extracts. The reagents used are:—(1) 0·5 grm. of magenta dissolved in 100 c.c. of water, and a solution containing 16 grms. of sulphur dioxide added. After standing until decolorised, the whole is made up to 1 litre. (2) 1 grm. of pure citral dissolved in and made up to 1 litre with 50 per cent. (by vol.) alcohol, free from aldehydes. The solution of the lemon oil or extract in alcohol is treated with a definite quantity of the magenta solution, and compared with standards prepared in an exactly similar manner with known quantities of citral. It is important that the comparison of colours be made at a temperature not above 15° C. The method gives very good results with lemon extracts, whilst, in the case of lemon oils, the maximum error is usually less than 0·5 per cent.—A. S.

Pinene and firpene; Chlor-hydrochlorides of ——. G. B. Frankforter and F. C. Frary. XIII*B*., page 1107.

Pitch and terpenes of the Norway pine and Douglas fir. G. B. Frankforter. XIII*B*., page 1107.

Origanum oil; Manufacture of ——. Bd. of Trade J., Nov. 1, 1906. [T.R.]

ACCORDING to the annual report for 1905–6 on Cyprus, the manufacture of origanum oil in the island, undertaken by the Agricultural Department, has during the last year assumed more important proportions, and a sample of the product was submitted to Professor Dunstan, F.R.S., of the Imperial Institute. The preliminary report showed that the oil was of good quality, and would sell readily to soap manufacturers, makers of perfumery, and dealers in essential oils, and actual sales were effected at remunerative prices. The Agricultural Department has been carrying on the distillation of this oil for some four years, and has proved that the product is easily made, and can be profitably disposed of in a ready market. The origanum plant, from which it is made, grows freely in the forests. Permission to utilise the plant can be obtained from the Department, which is ready to withdraw from the business, and to give advice and assistance to any approved person who may desire to engage in the industry.

FRENCH PATENTS.

Glycidic esters and aldehydes; Process for synthesising ——. G. Darzens. Fr. Pat. 361,698, Aug. 16, 1905.

A VARIETY of alkaline condensing agents can be used for condensing ketones with monohalogenated acetic esters, to form glycidic esters (see Fr. Pat. 337,175 of 1903; this J., 1904, 455); for example, a sodium alcoholate, sodium amide, sodium cyanamide, or dicyanodiamide. The glycidic esters may be saponified by either aqueous or alcoholic solutions of alkali hydroxides. The alkali salts may, in certain cases, be decomposed at once by distillation, *in vacuo*, or the free acids may be converted into the corresponding aldehydes by heating or by any other suitable means. A list is given of eighteen new β-glycidic esters and fourteen aldehydes obtained by the above process, all applicable to perfumery.—T. F. B.

Δ_4-Cyclogeranic acid; Process of making ——. Farbwerke vorm. Meister, Lucius, und Brüning. First Addition, dated Aug. 17, 1905, to Fr. Pat. 361,637, July 19, 1905.

THIS addition is for the purpose of including in the process (see U.S. Pat. 805,924 of 1905; this J., 1906, 39) the preparation of derivatives of Δ_4-cyclogeranic acids from isophoronecarboxylic acid.—T. F. B.

Hydroxy-derivatives of the benzene series; Process for preparing ——. Soc. Chim. des Usines du Rhône, ancien. Gilliard, P. Monnet et Cartier. Fr. Pat. 361,732, Aug. 31, 1905.

SEE Ger. Pat. 167,211 of 1904; this J., 1906, 608.—T. F. B.

Aminobenzoic acid alkamine esters [amino-alcohols] and their derivatives; Process of making ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 361,734, Aug. 31, 1905.

SEE Eng. Pat. 17,162 of 1905; this J., 1906, 607.—T. F. B.

Formates; Process of making ——. Nitritfabrik G.m.b.H. Fr. Pat. 367,088, April 13, 1906. Under Int. Conv., April 15, 1905.

SEE Eng. Pat. 9008 of 1906; this J., 1906, 909.—T. F. B.

Isoborneol esters; Direct process for preparing —— from pinene hydrochloride or hydrobromide. Chem. Fabr. von. Heyden A.-G. First Addition, dated June 5, 1906, to Fr. Pat. 365,814, May 1, 1906. (See Eng. Pat. 10,999 of 1906; this J., 1906, 714.)

FATTY acid esters of isoborneol may be obtained direct from pinene hydrochloride or hydrobromide by heating with a fatty acid and an oxide or carbonate of a heavy metal, or with fatty acid salts, oxide, or carbonate of magnesium, or of metalloids which form salts with acids (*e.g.*, vanadium, arsenic, antimony, or titanium); the zinc salts of organic acids, or inorganic acids not possessing oxidising properties may also be used, as also may the

halides of heavy metals, earths, or magnesium. 172 parts of pinene hydrochloride are boiled with 500 parts of 98 per cent. formic acid, 200 parts of antimony oxide, and 30 parts of ferric chloride, for 20 hours under a reflux condenser; the product is poured into water, washed, and distilled *in vacuo*. A good yield of isobornyl formate is said to be obtained. Thirteen other examples are given. —T. F. B.

Vanilla; Process and apparatus for preparing ——. L. de Montesquoiu. Fr. Pat. 367,285, June 9, 1906.

Vanilla beans collected in cool countries (*e.g.*, Guadeloupe) are usually dried rapidly, by artificial heat, but it is stated that by this method a portion of the vanillin is decomposed; to prevent this, it is proposed to place the beans, in single layers, between sheets of fabric, and to keep them for six to ten days at a uniform temperature of 60° C. This process is stated to produce beans as rich in vanillin as those prepared by natural heat in tropical countries, *e.g.*, Mexico.—T. F. B.

[*Alkyloxyacetyl*] *Esters of alcohols of the terpane or camphane group; Process for preparing new* ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 367,057, June 11, 1906. Under Int. Conv., Jan. 18, 1906.

An alkylhydroxyacetic acid or one of its derivatives (*e.g.*, chloride) is esterified by means of santalol, menthol, borneol, or other terpane or camphane alcohol, in presence of a suitable solvent. Thus, 122·5 parts of ethoxyacetyl chloride are added to a solution of 154 parts of borneol in 500 parts of benzene and 79 parts of pyridine; the product is washed first with dilute acid, and then with water, dried, and fractionated; ethoxyacetyl-borneol as thus obtained has a b.pt. of 175°—178° C. (20 mm. pressure).—T. F. B.

Hydrogen peroxide; Manufacture of ——. R. Wolffenstein. Fr. Pat. 367,199, June 16, 1906. Under Int. Conv., June 17, 1905.

Barium peroxide (or its "hydroxide") instead of being decomposed by water saturated with carbon dioxide (in which case the peroxide is liable to become coated by a layer of carbonate which arrests the reaction) is treated with water, and only so much carbon dioxide as may leave the solution alkaline, under which conditions it is stated that barium percarbonate (and perhaps a soluble "bipercarbonate") is formed, which is subsequently decomposed into barium carbonate and hydrogen peroxide on further treatment with carbon dioxide. Directions are given for dealing with solutions of varying strength.—E. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 1067.)

Photographic plates; Cause of the fogging of —— in tropical climates. J. McDowall. Chem. News, 1906, 94, 209.

Photographic plates which had been kept in wooden dark slides in Egypt, when the temperature was about 40° C., were found to fog badly on development; this was traced to vapours exhaled from the wood at the high temperatures, which reduced the silver halide. It can be prevented by interposing a piece of tissue paper between the plate and the shutter of the dark slide. —T. F. B.

English Patent.

Printing papers for use in photography; Self-toning silver chloride ——. O. H. Steudel, Dresden, Germany. Eng. Pat. 10,051, April 30, 1906.

"Self-toning" papers, as known at present, can only be toned to a purplish tint by the use of a special toning bath, in addition to the sodium chloride baths. The present invention relates to papers on which cold tones can be produced simply by the use of sodium chloride solution; this result is achieved by the addition of a lead salt (*e.g.*, the nitrate or acetate) to the emulsion, suitable proportions being 10 to 16 parts of lead nitrate and 2 to 5 parts of gold chloride to every 100 parts of silver in the emulsion. These papers are also stated to be more permanent as regards storage before use.—T. F. B.

French Patent.

Photographic paper which darkens directly; Preparation of a ——. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils. Fr. Pat. 361,720, Aug. 24, 1905.

Photographic "printing out" papers are obtained by incorporating a reducing agent with a silver salt emulsion; the reducing agent may be either a hydroxy-derivative of benzene, or an inorganic salt, such as a nitrite, arsenite, or manganous salt. Further details are given in the paper by Lumière (this J., 1906, 90).—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

(*Continued from page* 1068.)

Nitrocellulose; Causes of decomposition of, and methods for determining the degree of instability of——. M. Jacqué. Z. ges. Schiess- u. Sprengstoffwesen, 1906, 1, 395—8.

The author reviews the various tests proposed for determining the stability of nitrocellulose (this J., 1905, 148, 347; 1904, 953; 1903, 511, 924, 1208; 1902, 819—825, 1470—1, 1554; 1901, 8—13, 609—617; 1899, 174, 857—8; 1898, 1180; 1897, 283—290). The method proposed by the author is a modification of the test introduced by Sy. This consists in heating the sample of nitrocellulose (4 grms.) at a temperature of 115° C., for several days, for a period of eight hours per day, and determining the daily loss in weight. The latter, taken in conjunction with the time of heating, is an index of the stability of the compound. For purposes of factory control this test has the disadvantage of being rather prolonged, and the author has modified it as follows:—The sample to be tested is heated at 130°—140° C., and weighed after successive periods of heating of two hours duration. Nitrocellulose when dried to constant weight at 50°—60° C. still retains a certain percentage of moisture which is only driven off at temperatures above 100° C., or by prolonged exposure, *in vacuo*, over sulphuric acid. It is important that this last trace of moisture should be got rid of before beginning the test proper. From 2—3 grms. of nitrocellulose are placed in a glass dish provided with a light, well-fitting cover to prevent absorption of moisture during weighing. The sample is heated to constant weight at 50°—60° C. and afterwards for 10 minutes at 130° C. to drive off the last traces of moisture, and then weighed. It is kept for two hours at a temperature of 130°—140° C., cooled in a vacuum dessicator over sulphuric acid, and the loss in weight rapidly determined on a Curie balance. This process is then repeated some fifteen times further. The results are calculated on the basis of the *loss in mgrms per grm. of nitrocellulose* taken, and these are the figures which appear in the subjoined tables. In general, the samples are heated with free access of air. Should it be desired, however, to study the decomposition in the presence of the products of decomposition, the glass weighing vessel can be enclosed in another, provided with a cover fitting air-tight by means of a rubber ring and spring. In the author's experience it is only when the nitrocellulose is unstable, that the presence of the products of decomposition accelerates the rate of decomposition. Standard stable samples of nitrocellulose are prepared by careful purification in the laboratory, and the factory output is checked against these as a standard of comparison. The following tables show the effect of the various steps in the manufacture and purification and at the same time the corresponding results obtained by other tests are also given. For a description of Obermüller's manometer test see this J., 1905, 347. The fume test at 135° C. is carried out as follows:—Nitrocellulose (2·5 grms.) dried at 70° C., is filled into a tube 32 cm. long and 16 mm. diameter, to a height of 4 cm. The tube is corked and placed in a bath heated to 135° C., to a depth of 10 cm. At the expiration of ten minutes the moisture condensed in the upper part of the tube is removed with a piece of filter paper, and the tube recorked. A standard for estimating the depth of tint of the evolved oxides of nitrogen is obtained by filling one of the tubes with a

solution of 8 mgrms. of potassium bichromate and 0·4 grm. of cobalt sulphate dissolved in 1 litre of water.

Collodion cotton (11·8 *per cent.*—11·9 *per cent. N.*) *for blasting gelatin.*

Purification.—Boiled twice, before pulping, for 12 hours in slightly acid water. Washed six times for three hours. The boilings and washings are followed by rinsing with cold water.

Temperature of test 140° *C.*

***Explosives; Velocity of detonation of* ——.** M. Dautriche, Compt. rend., 1906, 142, 641—4.

THE method depends upon the use of detonating filaments. The velocity of detonation of such filaments, has been determined by placing the explosive in a tube some 50m. long, and determining the velocity by means of a Schultz chronograph owing to the breaking of the conducting wires at either end of the tube. The filaments used in the experiments had a determined regular velocity of 6500 m. per second. Such a filament can be utilised to register very accurately small intervals of time, since 1 mm. in length corresponds to $\frac{1}{6500000}$ part of a second. The experiment is carried out as follows:—Two lengths of filament of 2·2 m. are taken, and an end of each piece inserted in the opposite ends of a tube primed with fulminate. The free ends of the filaments are then overlapped for a length of 400 mm., and bound together. There is formed thus a circuit along which, after the primer of fulminate is exploded, the detonating waves in each filament meet in an opposite direction at a point midway along the overlap; *i.e.*, 2 m. from the end at which the explosion originates. If the filaments so arranged are detonated in contact with a sheet of lead of 25 mm. thickness, there is produced a depression in the lead corresponding to the position of the filaments, and at the point where the detonations have met, a very characteristic mark, lying at an angle of 45° to the direction of the filaments. If the point in the filaments where the detonations should meet, be placed on a line drawn on the sheet of lead, any displacement of the detonating mark from this index line can be measured. By lengthening one of the filaments by 100 mm., 200 mm., and 300 mm., measurements of displacement of 50 mm., 100 mm., and 145 mm., have been obtained. In order to determine the velocity of detonation of any explosive, one of the filaments is cut, and a tube of zinc, 20 mm. diameter and 50 cm. long, filled with the explosive, is interposed. The lengths of the filaments in the two branches of the circuit still remain equal, but a retardation of the velocity of the detonation results owing to the interposed explosive, with a consequent measurable displacement of the detonating mark described above. To compensate for the delay of transmission from filament to explosive, and again from explosive to filament, the other branch of the circuit can be furnished with a similar

halides of heavy metals, earths, or magnesium. 172 parts of pinene hydrochloride are boiled with 500 parts of 98 per cent. formic acid, 200 parts of antimony oxide, and 30 parts of ferric chloride, for 20 hours under a reflux condenser; the product is poured into water, washed, and distilled *in vacuo*. A good yield of isobornyl formate is said to be obtained. Thirteen other examples are given. —T. F. B.

Vanilla; Process and apparatus for preparing ——. L. de Montesquoiu. Fr. Pat. 367,285, June 9, 1906.

Vanilla beans collected in cool countries (*e.g.*, Guadeloupe) are usually dried rapidly, by artificial heat, but it is stated that by this method a portion of the vanillin is decomposed; to prevent this, it is proposed to place the beans, in single layers, between sheets of fabric, and to keep them for six to ten days at a uniform temperature of 60° C. This process is stated to produce beans as rich in vanillin as those prepared by natural heat in tropical countries, *e.g.*, Mexico.—T. F. B.

[*Alkyloxyacetyl*] *Esters of alcohols of the terpane or camphane group; Process for preparing new* ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 367,057, June 11, 1906. Under Int. Conv., Jan. 18, 1906.

An alkylhydroxyacetic acid or one of its derivatives (*e.g.*, chloride) is esterified by means of santalol, menthol, borneol, or other terpane or camphane alcohol, in presence of a suitable solvent. Thus, 122·5 parts of ethoxyacetyl chloride are added to a solution of 154 parts of borneol in 500 parts of benzene and 79 parts of pyridine; the product is washed first with dilute acid, and then with water, dried, and fractionated; ethoxyacetyl-borneol as thus obtained has a b.pt. of 175°—178° C. XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 1070.)

APPARATUS, &c.

Gases; Analysis of nearly pure ——. A. Stock and C. Nielsen. Ber., 1906, **39**, 3389—3393.

A SMALL, accurately-graduated burette is fused on to an ordinary Hempel absorption pipette, and the residual gas, after absorption of the main constituent, is returned to this for measurement. In analysing, for example, nearly pure oxygen, a number of determinations are first performed, so as to "wash out" by the oxygen any nitrogen dissolved in the absorbing reagent, of which the free surface is covered with liquid paraffin to reduce the absorption of nitrogen from the atmosphere to a minimum. The amount of nitrogen thus taken up by the oxygen diminishes in successive tests; finally, a small constant amount is always yielded by the reagent, but this error is too small to be of any consequence. The actual analysis of the oxygen to be tested is then carried out, and the amount of residual nitrogen measured as before. By means of the small burette, quantities such as 0·2 per cent. can be readily measured. The authors point out that water, which has been boiled to expel air, very rapidly absorbs this again: 1360 c.c. of water absorbed 5·8 c.c. of gas in less than two minutes.—E. F. A.

Distillation and desiccation in vacuo at low temperatures. D'Arsonval and Bordas. Compt. rend., 1906, **143**, 567—570.

THE apparatus consists of a condensing-tube, D, communicating on the one hand with the flask, C, or the bell-jar, A, containing the substance to be distilled or dried, and on the other with the tube, E, containing charcoal, and with the Crookes tube, G. On passing sparks through the latter, the nature of the discharge observed therein indicates the state of vacuum in the apparatus. The 3-way cock, F, allows of connection to a water-aspirator, or of communication between or separation of D and E. All the joints are ground and greased, and the tube connecting D and E reaches about three-quarters of the way to the bottom of D. To work the apparatus, the vacuum-vessel, filled with liquid air, or carbon dioxide dissolved in acetone, is gradually brought up over D, and the water-pump set in action. When the effect of this has reached its limit, it is shut off, the second vacuum vessel is brought up over E, communication between D and E established, and the apparatus left till the distillation or desiccation is complete, after which air is admitted. The height of the vacuum vessel round D must be regulated so as to avoid the condensation of solid matters on the end of the tube in D, and consequent blocking of this tube. Should the tube become blocked, the distillation must be interrupted, the apparatus taken apart, the tube, D, cleaned and replaced. With this apparatus, three hours suffice for the desiccation of extracts from wines, and a few minutes are enough for drying completely flours, sugars, serums, vaccines, &c.—J. T. D.

Nitrogenous constituents from malt extract, by porcelain filtration; Separation of ——. H. T. Brown and others. XVII., page 1112.

UNITED STATES PATENT.

Gas analysis; Apparatus for ——. A. Bayer, Brünn, Austria-Hungary. U.S. Pat. 834,040, Oct. 23, 1906.

THE apparatus comprises two gas-meters, connected with the gas pipe, which drive shafts in opposite directions, and an absorbent-container connected between the two meters. The motion of the shafts is transmitted by differential gearing to a toothed rim, which engages with a toothed wheel mounted on a third shaft, on which a friction pulley is also keyed. A sliding bar, guided to move vertically, is pressed against this pulley by a spring, and a style is mounted on the bar, and marks a rotary drum. A pinion with a lateral stud may be mounted on one of the first-named shafts, and combined with a toothed wheel, which, on rotating, causes the stud to engage a projection on a pivoted lever, actuated by a spring and pressed against the pulley, the lever also carrying a friction roller. Before entering the first meter, the gas passes through one compartment of a cooler, and after leaving the absorbent container, it passes through the second compartment of the cooler, before entering the last meter. The cooler consists of a vessel with chambers at the ends, separated by perforated partitions from the rest of the vessel. Each chamber is divided by a wall into two compartments, the compartments at one end of the vessel being provided with gas-inlets, and those at the other end with gas-outlets. The holes in one perforated partition are connected by pipes with the corresponding holes in the other partition, and water is made to circulate round the pipes. The apparatus also includes a solid absorbent container, comprising a vessel with a gas-inlet near the bottom, and an annular trough to hold a fatty sealing medium at the top. Into this trough the guttered rim of a cover fits, the cover being provided with a gas-outlet.—W. C. H.

INORGANIC—QUALITATIVE.

Nickel; Delicate reaction for ——. H. Grossmann and B. Schück. Ber., 1906, **39**, 3356—3359.

THE test depends on the formation of nickel-dicyandi-

amidine, $Ni(N_4H_5C_2O)_2.2H_2O$, which is a very slightly soluble, yellow precipitate of stellate-grouped needles. It is less soluble in ammonia than in water, and is not decomposed by boiling with potassium hydroxide solution. Potassium cyanide dissolves it readily. To apply the test, a five per cent. solution of dicyandiamide is boiled for a minute with a few drops of hydrochloric acid; the nickel solution is added, and then an excess of potassium hydroxide solution. In very dilute solutions the precipitate only comes down after long standing. The presence of a large excess of cobalt does not interfere with the reaction.—J. T. D.

INORGANIC—QUANTITATIVE.

Uranium and vanadium; Determination of ——. A. N. Finn. J. Amer. Chem. Soc., 1906, **28**, 1443—1446.

In the usual method for separating uranium and vanadium, the former is precipitated as alkali or ammonium uranate, but the precipitate is gelatinous, and cannot be washed free from vanadium. The author describes a method in which the uranium is precipitated as ammonium uranyl phosphate. An amount of the substance containing not more than 0·25 grm. of uranium oxide, U_3O_8, is dissolved in sulphuric acid (1:5), and the solution evaporated till white fumes appear. After cooling, the solution is diluted, an excess of sodium carbonate added, and the whole boiled until the precipitate settles well. The precipitate is filtered off, washed with hot water, dissolved in the smallest possible quantity of sulphuric acid, the solution diluted, an excess of sodium carbonate added, and the whole again boiled. The precipitate is filtered off and washed, and the combined filtrates and washings are acidified with sulphuric acid. Ammonium phosphate (about 0·5 grm.) is next added, the solution heated to boiling, and made alkaline with ammonia, and after boiling for a few minutes, the ammonium uranyl phosphate is filtered off, and washed with hot water containing a little ammonium sulphate. In the filtrate the vanadium is determined as usual by acidifying with sulphuric acid, reducing with sulphur dioxide, and titrating with permanganate. The uranium precipitate is dissolved in sulphuric acid, and the uranium determined in the ordinary manner by reducing with zinc and titrating with permanganate.—A. S.

Beryllium; Separation of —— from aluminium. R. Glassmann. Ber., 1906, **39**, 3366—3367.

The solution is nearly neutralised by sodium carbonate, excess of sodium thiosulphate added, the liquid boiled till all sulphur dioxide is expelled, then heated for half an hour longer on the water-bath, and filtered. The precipitated alumina and sulphur are ignited together, and the remaining alumina is weighed. The beryllium in the filtrate, after destroying excess of thiosulphate with hydrochloric acid, is precipitated either by ammonia or, by iodide and iodate (see following abstract).—J. T. D.

Beryllium; Determination of ——. R. Glassmann. Ber., 1906, **39**, 3368—3369.

Beryllia is precipitated completely from hot solutions of beryllium salts by a mixture of potassium iodide and iodate; the completion of the reaction is hastened by removing the resulting iodine by means of thiosulphate, and the precipitate is in a form which rapidly subsides and can be easily and thoroughly washed. The solution must be neutral or very slightly acid; to it is added excess of a mixture of equal volumes of 25 per cent. potassium iodide solution and saturated potassium iodate solution. After about five minutes the separated iodine is exactly decolorised by 20 per cent thiosulphate solution, a few c.c. of the iodide-iodate solution are added in order to ensure that excess is present, then a few drops of the thiosulphate solution, and the liquid is heated on the water-bath for half an hour. The precipitate is filtered off through filter-paper of open texture, washed with boiling water, ignited, and weighed.—J. T. D.

Gold; Electrolytic precipitation of —— with the use of a rotating anode, [and electrolytic analysis of alkali halides]. J. E. Withrow. XIB., page 1103.

Silver chloride; Solubility of —— in hydrochloric acid and in sodium chloride solutions. [Determination of sulphur in organic compounds.] W. E. Barlow. J. Amer. Chem. Soc., 1906, **28**, 1446—1449.

Dudley (Amer. Chem. J., 1902, **28**, 62) has shown that when sodium dioxide is fused in a silver crucible, the metal is rapidly attacked, a complex oxide being formed. If the melt be evaporated or heated with hydrochloric acid (as in the method of determining sulphur by fusion with sodium dioxide), the silver is converted into chloride, which dissolves to a certain extent in the solution. Barium sulphate precipitated in such solutions almost invariably contains silver. Determinations of the solubility of silver chloride in solutions of sodium chloride and of hydrochloric acid showed that in sodium chloride solutions the amount dissolved decreases at a gradually diminishing rate as the concentration of sodium chloride is reduced, and that in hydrochloric acid solutions, the solubility is directly proportional to the concentration of the acid. As an example, it may be stated that 300 c.c. of solution containing 23 grms. of sodium chloride dissolved 0·0745 grm. of silver chloride at 90° C., whilst at the same temperature, 300 c.c. of a solution containing 10 c.c. of concentrated hydrochloric acid dissolved 0·0169 grm. The author recommends the use of a nickel dish in making determinations of sulphur by fusion with sodium peroxide.—A. S.

ORGANIC—QUALITATIVE.

Catechu; Detection of adulteration in ——. D. Hooper. Agric. Ledger, 1906, [3], 44—45.

One to two grms. of finely-divided catechu are digested for 24 hours with 90 per cent. alcohol, with occasional agitation; the extract is removed, and the residue washed until colourless, the extract and washings being then evaporated to dryness at 100° C.; a good quality of catechu should yield 70 per cent. of extract and upwards, and a fair quality, 60 to 70 per cent., whilst 50 per cent. or less should be regarded as very inferior. The Indian and Colonial Addendum to the Brit. Pharmacopœia gives 80 per cent. as the limit of extract, which is considered too high; the same work also mentions 6 per cent. as the maximum for ash, whilst the U.S. Pharmacopœia gives 5 per cent.; the average ash content of a large number of samples of Burmese cutch was only 2·9 per cent.—T. F. B.

ORGANIC—QUANTITATIVE.

Silk; Determination of the weighting of ——. J. Persoz. Rev. Gen. Mat. Col., 1906, **10**, 321—328.

The following process has been used by the author for a number of years for the determination of the weighting of black silks:—The silk is dried by keeping for some time in a dry place at the ordinary temperature; drying at higher temperatures removes moisture which it is considered should be regarded as weighting. The dry sample is heated for some time in dilute ammonia, and then subjected to successive extractions in the cold with hydrochloric acid (1 vol. of 30 per cent. acid to 3 vols. of water) and subsequently with caustic soda solution (4° to 4·5° B.), until the acid extracts give no precipitate, or only a very slight one, with ammonia. It is advantageous to add alkali sulphide to the alkali solution, as this aids in the removal of the tin. One of the extractions with hydrochloric acid is replaced by extraction with dilute hydrofluoric acid (1·5 per cent.) at 60° C. In all cases tried except one, this had the effect of producing a silk fibroïn which gave no ash on incineration. The silk is finally, washed, dried, and weighed. The percentage weighting can then be calculated from the expression $(100 - n)\frac{a}{b} - 100$, where a = weighted silk used, b = pure silk obtained, n = per cent. decrease in weight of original (unweighted) silk on boiling off. For silks other than black, extraction with hydrofluoric acid is recommended as generally applicable, the extent of weighting being calculated in the known manner from the percentage of ash obtained from the extracted silk. (See also Gnehm and Dürsteler, this J., 1906, 1090.)—T. F. B.

Reducing substances and their determination. H. Pellet. Internat. Comm. for standard methods of sugar analysis, Berne, 1906; Z. Ver. Deutsch. Zuckerind., 1906, 1012—1022.

Of the numerous copper solutions recommended for the determination of reducing substances in products of sugar manufacture, the author gives preference to that proposed by Violette. It is prepared as follows: 34·66 grms. of crystallised copper sulphate are dissolved, and made up to 500 c.c. with distilled water; 200 grms. of Rochelle salt and 130 grms. of caustic soda are dissolved and made up to 500 c.c. Equal volumes of the solutions are mixed as required. Ten c.c. of the mixture are equivalent to 0·050 grm. of invert sugar. The author recommends the following volumetric process for products containing small quantities of reducing bodies, and which are not too dark in colour: 2, 5 or 10 c.c. of Violette's solution are measured into a boiling tube (length 20—22 cm., diameter 20 mm.); the solution under investigation is then added in small portions, the whole being boiled after each addition. The end point of the reaction is indicated by the disappearance of the blue colour, and is readily detected after a little practice, even in artificial light. If excess of reducing solution has been added, the liquid becomes yellow in colour. The copper solution is standardised with a solution containing 0·050 grm. of invert sugar per 10 c.c. and a small quantity of salicylic acid, to render it more stable. If the sample contain a very small quantity of reducing bodies, the standardising solution of invert sugar must be correspondingly diluted. For products the colour of which does not permit the use of the above process, the author recommends the following modification of the gravimetric process. If the sample contain a large proportion of reducing substance, it must be diluted so as to contain 5—10 grms. of reducing substance per litre. If necessary, the solution is heated with a trace of sodium carbonate to remove a possible excess of calcium salts; it is then filtered in order to remove suspended mineral matter, 40 c.c. of the copper solution are poured into a Bohemian flask of special glass, and 20 or 10 c.c. of the solution under investigation are added, the total volume being made up to 60 c.c. The flask is then heated in a boiling water-bath which contains so much water that the surface of the outer liquid is slightly above that of the solution in the flask. The solution is heated to 85°—88° C., and kept at this temperature for three minutes; 50 c.c. of distilled water are then added, the flask is shaken, the cuprous oxide allowed to settle somewhat, and then filtered off through an ashless filter (9—11 c.m. diameter) previously moistened with water, and finally washed with hot water until the washings are neutral. The precipitate and filtrate are incinerated (preferably in a muffle heated with gas or electricity), the copper oxide (CuO) being weighed. From 2—5 mgrms. must be subtracted from the weight of copper oxide to compensate for the absorption of salts by the filter paper; the actual amount must be directly determined. The amount of invert sugar is determined by multiplying the weight of cupric oxide by 0·454. For very accurate work, however, the coefficient must be determined by a control analysis with invert sugar. The above method possesses the following advantages over those which involve boiling the copper and sugar solutions:—(1) Several determinations can be made simultaneously; (2) heating is very uniform; (3) reduction is complete; (4) influence of secondary products, and especially of sucrose, on the copper solution, is diminished. Numerous experiments have shown that heating to 85°—88° C. is sufficient to cause reduction by all the reducing substances; the method gives very concordant results, and clarification with lead acetate is unnecessary.

Supplement 1.—In filtering the alkaline copper solution through filter paper, the latter retains both copper and tartrate.

Supplement 2.—The author quotes analyses from various sources which show that Clerget's inversion method gives an accurate result for the amount of crystallisable sugar in a product containing this together with invert sugar.

Supplement 3.—The author is of the opinion that the reducing substances in cane and beetroot sugar products are identical, that they differ only in amount, and that they consist of dextrose and lævulose in varying proportions. If, in the determination of the invert sugar in molasses by the gravimetric method above described, the heating be continued considerably beyond the prescribed period, a much higher result is sometimes obtained than that obtained under normal conditions. The author does not consider that this is due to the presence of reducing substances, other than lævulose and dextrose, in the molasses, but that it is caused by non-reducing substances which act on alkaline copper solution during protracted heating. Hence, by using the gravimetric process described above, and adhering to the conditions defined, the amount of lævulose and dextrose is determined accurately.—L. E.

Citral in lemon oils and extracts; Method for the determination of ——. E. McK. Chace. XX., page 1116.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 1070.)

Steam; Dissociation of ——. H. v. Wartenberg. VII., page 1093.

Steam; Dissociation of ——. W. Nernst and H. v. Wartenberg. VII., page 1094.

Carbon dioxide; Dissociation of ——. W. Nernst and H. v. Wartenberg. VII., page 1094.

Water vapour and carbon dioxide; Dissociation of —— at high temperatures. I. Langmuir. VII., page 1094.

Nickel and cobalt; Distribution of —— in nature. K. Kraut. Z. angew. Chem., 1906, **19**, 1793—1795.

With the aid of Tschugaeff's reagent (dimethylglyoxime; see this J., 1905, 941), the author has proved the presence of nickel in the ashes of a number of German peats and coals, and in tufa from Vesuvius. If the nickel compound, after evaporation to dryness, be taken up with water and ammonia and a little additional oxime, and filtered off, any associated cobalt passes into the filtrate; and on adding to this, hydrogen sulphide or ammonium sulphide, a blue-violet or deep red coloration is struck, which forms a most delicate test for cobalt. Most of the peat- and coal-ashes mentioned, showed the presence of cobalt when thus tested, as did also the spent salt from a potash factory.—J. T. D.

Colloidal solutions; Action of electrolytes on ——. E. F. Burton. Phil. Mag., 1906, **12**, 472—478.

Very dilute solutions of aluminium sulphate were added to colloidal solutions of silver (containing 65 mgrms. per litre) and of gold (62 mgrms. per litre), and the velocity of migration of the particles was measured. It was found to lessen as the amount of electrolyte added, increased till it passed through zero, and then after changing sign gradually increased. The original solutions, and those containing enough electrolyte to impart a considerable reversed speed, were stable, while those exhibiting a slow speed in either direction, readily coagulated. The results confirm those of Hardy on egg-albumin, and indicate that the metallic particles absorb the metallic ions, and thus neutralise their charges; when the isoelectric point is reached, the surface tension of the particles is a maximum, and they tend to decrease the surface exposed to the liquid by uniting with each other, thus bringing about coagulation.—J. T. D.

Methylamine; Liquid —— as a solvent, and a study of its chemical activity. H. D. Gibbs. J. Amer. Chem. Soc., 1906, **28**, 1395—1422.

Liquid methylamine is a remarkably good solvent for organic compounds, being better in this respect than liquid ammonia, and also, probably, than methyl alcohol. It is not such a good solvent for inorganic compounds as liquid ammonia is. It combines readily with both organic and inorganic compounds, and new addition products of methylamine with the following compounds have been prepared: Phenol, quinol, resorcinol, α-naphthol, *m*-nitrobenzaldehyde, acetic acid, phenylacetic acid,

diphenyl-ketoxime, nitromethane, bismuth chloride, cadmium iodide, calcium chloride, chromic chloride, lithium chloride, lithium nitrate, lead nitrate, mercuric chloride, methyl-mercuric chloride, mercuric iodide, and silver nitrate.—A. S.

Reversible reactions among organic acid derivatives. J. Biehringer and W. Borsum. Ber., 1906, 39, 3348—3356.

The qualitative conditions are discussed under which a number of simple interactions of derivatives of organic acids take place in either direction. Thus, in sealed tubes at 150° C., benzoic acid and acetyl chloride form benzoyl chloride and acetic acid, but at 120° C., under ordinary pressure, change proceeds in the contrary direction. Whereas the interaction of benzoic acid and acetamide takes place in one direction only, ethyl acetate and benzamide yield acetamide and ethyl benzoate when heated for six hours under pressure at 260° C., whilst the reverse change takes place on heating under pressure from 270°—290° C. Phenyl benzoate and ammonia interact in sealed tubes at 150° C., whilst benzamide and phenol yield phenyl benzoate on heating. Other cases considered, are the interaction of oxalic acid and acetamide, of benzoic acid and acetanilide, and of acetanilide and benzoyl chloride.—E. F. A.

Trade Report.

Patent Law Reform.

Chem. of Com. J., Nov., 1906.

A deputation from the Associated Chambers of Commerce waited upon the President of the Board of Trade on Oct. 18, in continuation of the larger deputation on April 9, on the subject of Patent Law Amendment. Although the proceedings were private, it is understood that the Government intend to introduce a Bill into Parliament at an early opportunity, dealing with the grievances of the manufacturing and commercial community in regard to the present working of the Patents Act.

Australian Commerce Act Regulations.

Chem. of Com. J., Nov., 1906.

With reference to the new Australian Commerce Act, the following is the text of Part II. of the (Amended) Provisional Regulations relative to imported goods, and which become operative on Jan. 1, 1907:—

5. (1) The importation of the goods enumerated in this regulation is prohibited unless there is applied to the goods a trade description in accordance with this Part.

(2) The goods to which this regulation applies are as follows:—

(*a*) Articles used for food or drink by man, or used in the manufacture or preparation of articles used for food or drink by man;

(*b*) Medicines or medicinal preparations for internal or external use;

(*c*) Manures, including all articles for use as fertilisers of the soil, except farmyard or stable manures, and crude materials for the manufacture of manures;

(*d*) Apparel (including boots and shoes), and the materials from which such apparel is manufactured;

6. (1) The trade description to be applied in accordance with this Part shall comply with the following provisions:—

(*a*) It shall be in form of a label or brand affixed in a prominent position to the goods, or to the coverings containing the goods; and

(*b*) The label or brand shall set out in legible characters a true description of the goods, and the name of the country or place in which the goods were made or produced; and

(*c*) In cases where any weight or quantity is set out, the label or brand shall specify whether the weight or quantity so set out is gross or net.

(2) In the case of the following goods, the trade description shall, in addition, comply with the following provisions:—

(*a*) In the case of medicines prepared ready for use, and containing 10 per cent. or more of ethyl alcohol, if the average dose recommended exceeds one teaspoonful (60 minims), the trade description shall set out the proportion or quantity of alcohol in the medicine.

(*b*) In the case of medicines prepared ready for use, and containing any of the following drugs (or the salts or derivatives thereof), *viz.*:—Opium, morphine, cocaine, heroin, stramonium, nux vomica, cannabis indica, bromides, sulphonal, trional, veronal, paraldehyde, or any synthetic hypnotic substance, phenazonum, phenacetinum, or acetanilidum, or any allied synthetic substance, chloral hydrate, belladonna, cotton-root, ergot, or any abortifacient, the trade description shall set out the names of all such drugs so contained.

(*c*) In the case of manures, the trade description shall set forth the principal active constituent thereof.

(*g*) In the case of leather containing any loading of any mineral or other weighting substance, the trade description shall state the name of the loading or other weighting substance contained in the leather, and the percentage thereof.

New Books.

The Cyanide Process. An Introduction to the Cyanide Process, including the Determination of the Applicability of the Process to an Ore. By Alfred S. Miller. Second Edition, revised and enlarged. John Wiley and Sons, New York. Chapman and Hall, Ltd., London, 1906. Price 4s. 6d. net.

Small 8vo volume, containing 89 pages of subject matter, 29 illustrations, table of atomic weights, and the alphabetical index. The text is subdivided as follows:—I. General description of the cyanide process. II. Interfering substances. III. Chemistry of the cyanide process. IV. Determining the applicability of the cyanide process to an ore. V. Notes as to strengths of solutions, and general processes. VI. Special descriptions of some cyanide processes. VII. Volumetric methods.

The Mineral Industry during 1905: Its Statistics, Technology, and Trade. Founded by Richard P. Rothwell. Edited by W. R. Ingalls. Vol. XIV. Engineering and Mining Journal, New York and London, 1906. Price, £1 0s. 10d., or 5 dollars.

Large 8vo volume, containing 728 pages of subject matter, and the alphabetical index. There is a staff of 51 contributors, the names of whom, with their subjects, are given on the first page. The subjects treated of, after an introduction setting forth the methods pursued in the volume, are the following:—I. Aluminium. II. Antimony. III. Arsenic. IV. Asbestos. V. Asphaltum. VI. Barytes. VII. Bauxite. VIII. Bismuth. IX. Borax. X. Bromine. XI. Carborundum. XII. Cement. XIII. Chromium and Chrome Ore. XIV. Coal and Coke. XV. Copper. XVI. Copperas. XVII. Corundum and Emery. XVIII. Fluorspar. XIX. Fuller's Earth. XX. Garnet. XXI. Gems and Precious Stones. XXII. Gold and Silver. XXIII. Graphite. XXIV. Gypsum. XXV. Iron and Steel. XXVI. Lead. XXVII. Limestone. XXVIII. Magnesite. XXIX. Manganese. XXX. Mica. XXXI. Molybdenum. XXXII. Monazite. XXXIII. Nickel and Cobalt. XXXIV. Petroleum. XXXV. Phosphate Rock. XXXVI. Platinum. XXXVII. Potassium Salts. XXXVIII. Mercury. XXXIX. Salt. XL. Sodium, and Soda Salts. XLI. Sulphur and Pyrites. XLII. Talc and Soapstone. XLIII. Tin. XLIV. Tungsten. XLV. Zinc. XLVI. Progress in Ore-dressing and Coal-washing in 1905. XLVII. Improvements in Sampling and Assaying. XLVIII. Statistics of Production and Commerce.

Mines and Quarries: General Report and Statistics for 1905. Part II.—Labour. [Cd. 3179.] Wyman and Sons, Fetter Lane, London, E.C. Price, 10d.

This publication contains a general report and statistics relating to persons employed, and accidents at mines and

quarries in the United Kingdom, and to the enforcement of the Mines and Quarries Acts. According to these statistics the total number of persons employed at mines and at the quarries under the Quarries Act in the United Kingdom and the Isle of Man during the year 1905 was 982,343, of whom 887,524 were employed in or about mines, and 94,819 in or about quarries. Compared with the preceding year, there is an increase of 10,467 persons employed at mines. In 1905, 1103 separate fatal accidents occurred in or about mines and quarries, causing the loss of 1304 lives, showing a decrease of 55 in the number of fatal accidents and an increase of 102 in the number of lives lost as compared with 1904.

CHURCH'S LABORATORY GUIDE. A Manual of Practical Chemistry for Colleges and Schools, specially arranged for Agricultural Students. Revised and partly re-written by EDWARD KINCH, F.I.C., &c., Professor of Chemistry in the Royal Agricultural College, Cirencester, &c. 8th Edition. Gurney and Jackson, 10, Paternoster Row, London, E.C. Oliver and Boyd, Edinburgh. 1906. Price, 6s. 6d. net.

SMALL 8vo volume, containing 336 pages of subject matter, with 42 illustrations. The subject matter is subdivided as follows:—I. Chemical Manipulation. II. Qualitative Analysis. III. Quantitative Analysis, which includes: (i.) Sampling and Analysis of Manures; (ii.) Analysis of Soils; (iii.) Analysis of Waters; (iv.) Analysis of Foods.

DIE ELEKTROCHEMISCHEN DEUTSCHEN REICHSPATENTE. [Monographien über angewandte Elektrochemie, XXIV Band.] Auszüge aus den Patentschriften gesammelt, geordnet und mit Hinweisen versehen von Dr. P. FERCHLAND und Dr. P. REHLÄNDER. Wilhelm Knapp's Verlag, Halle a. S. 1906. Price, M. 10.

8vo volume, containing 230 pages of subject-matter, with 124 illustrations. The text is distributed under the following heads:—PART I. INORGANIC ELECTROCHEMISTRY. —I. Light Metals. II. Alkalis and Halogens. III. Hypochlorites ("Bleaching Liquor"). IV. Oxygenated Salts. V. Alkaline Earths. VI. Carbides. VII. Water Decomposition. VIII. Ozone. IX. Nitrogen Compounds. X. Heavy Metals. XI. Compounds of the Heavy Metals. XII. Apparatus. XIII. Furnaces. PART II. ORGANIC ELECTROCHEMISTRY.—I. Aniline. II. Benzidine and its Intermediate Products. III. Paraminophenols. IV. Dyestuffs and Intermediate Products. V. Pharmaceutical Products. APPENDIX.—Brief Abstracts of Patents granted during period from Jan. 1, 1905, to May, 1906. Also Patents which were still in force in May, 1906.

PROBENAHME UND UNTERSUCHUNG VON KOKS, KOHLEN, UND BRIKETTS. Taschenbuch für Chemiker, Hütteningenieure, Kohlen- und Zechenlaboratorien und Gasanstalten. Von Dr. ADOLF BERTHOLD. G. D. Baedeker, Verlagsbuchhandlung, Essen-Ruhr. 1906. Price, M. 2.

SMALL volume of pocket-book size, containing 61 pages with 37 illustrations, and an alphabetical index. The text is subdivided as follows:—I. Investigation of Cokes, including Sampling. II. Investigation of Coals and Briquettes, inclusive of Sampling.

PRODUCER GAS. By J. EMERSON DOWSON and A. T. LARTER, B.Sc., &c. Longmans, Green, and Co., 39, Paternoster Row, London, New York, and Bombay. 1906. Price, 10s. 6d.

8vo volume, containing 276 pages of subject matter, including two Appendixes, filling 24 pages, and the alphabetical index. There are 73 illustrations. The subject matter is subdivided as follows:—I. Theory of Producer Gas. II. Furnace Work. III. Heating Work. IV. Engine Work. V. Suction Plants. VI. Gas from Bituminous Coal for Engine Work. VII. Stand-by Losses. VIII. Comparison of Gas and Steam Power. IX. Fuel. X. Analysis of Fuel and of Producer Gas. XI. Calorific Power of Solid and Gaseous Fuels. XII. Practical Notes. XIII. (Appendix) Theoretical Explanations and Reference Data.

SMALLER CHEMICAL ANALYSIS. By G. S. NEWTH. Demonstrator in the Royal College of Science, London, &c. Longmans, Green, and Co., 39, Paternoster Row, London, New York, and Bombay. 1906. Price, 2s.

SMALL 8vo volume, containing 144 pages of subject matter, with 16 illustrations, and the alphabetical index. It is "practically an abridged edition of the qualitative section of" the author's "Manual of Chemical Analysis," and designed for students taking a less advanced stage than those for whom the latter and larger work was intended.

MINES AND QUARRIES: GENERAL REPORT AND STATISTICS FOR 1905. PART III.—OUTPUT. [Cd. 3196.] Wyman & Sons, Fetter Lane, London, E.C. Price 1s. 6d.

THIS return, which is prepared annually by the Home Office, contains statistics as to the quantity and value of various minerals raised in the United Kingdom. The value of the mineral output of the United Kingdom in 1905 was £95,870,723, a decrease of £1,606,916 as compared with the preceding year.

IMPERIAL INSTITUTE. Indian Section. Annual Report for the year 1905-6. [Cd. 3216.] Wyman & Sons, Fetter Lane, London, E.C. Price 2½d.

THIS report deals with the work of the Indian Section of the Imperial Institute during the year ended 31st March last. To the statement of the Indian Committee of the Imperial Institute is appended a report by Professor Wyndham Dunstan, F.R.S., on the Indian work of the Imperial Institute, together with a detailed account by Mr. C. E. Jones, superintendent of the Indian Section, on the work of the section during the year. A report by Mr. B. J. Rose on the Indian Trade Inquiry Office at 73, Basinghall Street, E.C., is also appended.

COLONIAL IMPORT DUTIES RETURN. [Cd. 3195.] Wyman & Sons, Fetter Lane, London, E.C. Price 2s. 6d.

THIS is a new issue of the return, showing the rates of import duty levied in the British Colonies, Possessions, and Protectorates, upon the principal and other articles of trade, which is prepared annually in the Statistical Department of the Board of Trade. The present issue contains a statement of the duties in force in 1906. The duties leviable in British Protectorates are, for the first time, incorporated in the body of the return, with the exception of those enforced in the Federated Malay States, British North Borneo, Sarawak, and Zanzibar, which are given as appendices.

FOREIGN IMPORT DUTIES, 1906. [Cd. 2340.] Wyman & Sons, Fetter Lane, London, E.C. Price 2s. 10d.

THIS return, which has been prepared in the Commercial Department of the Board of Trade, contains a statement of the rates of import duty, with their equivalents in English weights and currency, which are leviable in the principal European countries, the United States, China, Japan, Egypt, Persia, and Mexico, upon textiles, manufactures of iron and steel and other metals, earthenware, glass, leather and india-rubber wares, paper, stationery and books, paints, chemicals, articles of food, and numerous other articles of trade when imported from the United Kingdom. The changes observable on a comparison of this return with that issued a year ago [Cd. 2797] are numerous and important, owing mainly to the enforcement during the current year of new tariffs in Switzerland, Bulgaria, Russia, Germany, Austria-Hungary, Roumania, Spain, and Japan, while important alterations have also been made in the tariffs of Italy, France, Sweden, Belgium, and Greece. Particulars as to Mexico are included for the first time. A table is included showing the equivalent in English weights and currency of such rates of duty expressed in various foreign weights and currency.

Journal of the Society of Chemical Industry

No. 23.—Vol. XXV. SUPPLEMENT. DECEMBER 15, 1906.

HON. TREASURER:—
Samuel Hall, East London Soap Works, Bow, E.

PRESIDENT:—
Eustace Carey.

GENERAL SECRETARY:—
Charles G. Cresswell.

EDITOR:—
Watson Smith, 24, Upper Phillimore Gardens, Kensington, W.

OFFICES:—
Telegraphic Address: "Soci Palatable, London." 59, Palace Chambers, Westminster, S.W. Telephone No.: 715 Victoria.

Journal and Patent Literature.

Class.		Page.
I.—General Plant, Apparatus and Machinery		1135
II.—Fuel, Gas, and Light		1138
III.—Destructive Distillation, Tar Products, Petroleum, and Mineral Waxes		1140
IV.—Colouring Matters and Dyestuffs		1142
V.—Preparing, Bleaching, Dyeing, Printing and Finishing Textiles, Yarns, and Fibres		1143
VI.—Colouring Wood, Paper, Leather, &c.		—
VII.—Acids, Alkalis, and Salts, and Non-Metallic Elements		1145
VIII.—Glass, Pottery, and Enamels		1147
IX.—Building Materials, Clays, Mortars, and Cements		1148
X.—Metallurgy		1149
XI.—Electro-Chemistry and Electro-Metallurgy		1155
XII.—Fatty Oils, Fats, Waxes, and Soaps		1157
XIII.—Pigments and Paints; Resins, Varnishes, &c.; India-Rubber, &c.		[illegible]
XIV.—Tanning; Leather; Glue, Size, Bone, and Horn; Ivory and Substitutes		[illegible]
XV.—Manures, &c.		[illegible]
XVI.—Sugar, Starch, Gum, &c.		[illegible]
XVII.—Brewing, Wines, Spirits, &c.		[illegible]
XVIII.—Foods; Sanitation; Water Purification; and Disinfectants		[illegible]
XIX.—Paper, Pasteboard, Cellulose, Celluloid, &c.		[illegible]
XX.—Fine Chemicals, Alkaloids, Essential Oils, and Extracts		[illegible]
XXI.—Photographic Materials and Processes		[illegible]
XXII.—Explosives, Matches, &c.		[illegible]
XXIII.—Analytical Chemistry		[illegible]
XXIV.—Scientific and Technical Notes		[illegible]

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
Empire.—6d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1s. each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Bellu et Cie., 16, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the By-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this By-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896—1905.

IMPORTANT NOTICE.

The Hon. Treasurer is prepared to receive subscriptions for the Decennial Index (1896—1905). The Authors' Names portion is now in the press and will be issued early in the new year; and the subject-matter portion will follow as soon as possible afterwards. The price is 10s. for the whole Index, or 11s. ($2.75) post free.

Copies of the Collective Index (1881—1895) may be had at the same price.

Cheques of members' own bankers, or money orders, payable at the G.P.O., London, should be made payable to Samuel Hall and sent to the Hon. Treasurer, East London Soap Works, Bow, E., with the signed by-leaf of a similar which will be sent out with the ordinary subscription notice, and to any others who make application for it.

[illegible] OF MEMBERS ABROAD.

For the greater convenience of members abroad, arrangements have been made whereby cheques on their own bankers, drawn in the usual way and in their own currency, will be accepted in payment of subscriptions. [illegible] and money orders on G.P.O., London, should be payable to Samuel Hall, and forwarded to him at [illegible].

The return, whenever possible, of the [illegible] to the subscription notice, is specially recommended as a means whereby the sender may be assured that changes of address recorded, on which depends the receipt of the Journal.

"INDUSTRIAL DISEASES COMMITTEE."

With reference to a notice which appeared in the November 15th issue of the JOURNAL (p. 1035), announcing the appointment of a Departmental Committee to inquire and report what diseases and injuries, other than injuries by accident, are due to [illegible] and are distinguishable as such, and can properly be added to the diseases enumerated in the Third Schedule of the Workmen's Compensation Bill, 1906," members who desire to assist the Committee by tendering evidence are requested to communicate with the Society.

Changes of Address.

Abbott, Edwin, [illegible]; Woodside, Long Island, U.S.A.

Anderson, L. A., all communications to Box [illegible], 2, Wall Street, New York City, U.S.A.

Bateman, Sir Richard, [illegible]; Thornton, Chesterfield, Derbyshire.

Bateman, Sir Richard, [illegible]; Bateman, Chesterfield, Derbyshire.

Cramer, A., Jun.; Journals to 882, East 29th Street, Paterson, N.J., U.S.A.

Change of Name and Address.

Levy-Mond (formerly Levy) Dr. Albert, l/o South Wales; 15, Alphonsstrasse, Aachen, Germany, Chemical Engineer.

Change of Address Required.

Christie, Dr. W. A. K., l/o Penywern Road, Clydach, R.S.O., South Wales.

Deaths.

Chandler, Prof. Wm. H., Lehigh University, South Bethlehem, Pa., U.S.A., Nov. 30.
Poole, Herman, 331, West 57th Street, New York City, U.S.A.

Patent List.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 26,150. Von Radlovski. *See under* IX.
" 26,241. Hunt. Continuous vacuum filter. Nov. 20.
" 26,507. Blair. Apparatus for separating in water materials of different specific gravity. Nov. 22.
" 26,732. Weekes. Kilns and the like. Nov. 24.
[A.] 26,864. Jensen (Gaara). Rotary filters. Nov. 26.
" 26,875. Warren. Rotary kilns.* Nov. 26.
" 27,064. Symonds. Apparatus for measuring and recording the temperature of furnaces or the like. Nov. 28.
[C.S.] 24,175 (1905). Hulme and Crosfield. Centrifugal machines. Nov. 28.
" 1665 (1906). Haslam. Apparatus for drying and cooling air. Dec. 5.
" 3458 (1906). Mower and Bassett. Drying kilns. Dec. 5.
" 15,285 (1906). Draper (Christ). Apparatus for separating substances of different specific gravities. Nov. 28.
" 20,894 (1906). Allison (Christ). Apparatus for separating substances of different specific gravities. Nov. 28.

II.—FUEL, GAS, AND LIGHT.

[A.] 26,209. Kirke (Kirke). Manufacture of a hydrocarbon fuel. Nov. 19.
" 26,306. Zwicky. Carburetting apparatus. [Swiss Appl., Nov. 21, 1905.]* Nov. 20.
" 26,314. Smith. Carburetting air and mixing gases.* Nov. 20.
" 26,542. Barlen. Vertical coke oven. [Ger. Appl., Feb. 9, 1906.]* Nov. 22.
" 26,641. Lee. Metallic filaments for electric lamps. Nov. 23.
" 26,698. Kurzer. Apparatus for gasifying oils and carburetting air. [Ger. Appl., Nov. 30, 1905.]* Nov. 24.
" 26,819. Thwaite. Generation of combustible gas. Nov. 26.
" 26,882. Brown. Ovens for the manufacture of coke for metallurgical purposes. Nov. 27.
" 26,994. Hersey. Apparatus for separating cyanogen from coal gas. Nov. 27.
" 27,247. Hess. Apparatus for purifying gases.* Nov. 30.
" 27,355. Crossley and Rigby. Manufacture of producer gas. Dec. 1.
[C.S.] 23,966 (1905). Walker. Apparatus for the manufacture of air gas. Nov. 28.
" 25,046 (1905). McRae and Ingram. Manufacture of acetylene gas. Dec. 5.
" 1397 (1906). Stauber. *See under* III.
" 1417 (1906). Dowson. Gas generators. Dec. 5.
" 14,947 (1906). Siemens. Regenerative gas furnaces. Nov. 28.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 24,886. Williams. *See under* XII.
[C.S.] 1397 (1906). Stauber. Ovens for coking or carbonising peat, wood, or the like. Nov. 28.
" 14,263 (1906). Emery. Lubricating compounds. Dec. 5.

IV.—COLOURING MATTERS AND DYESTUFFS

[A.] 26,190. Johnson (Badische Anilin und Soda Fabrik). Manufacture of thioindoxyl derivatives Nov. 19.
" 26,416. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of *o*-oxymonoazo colouring matters Nov. 21.
" 26,508. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of *o*-oxydisazo colouring matters. Nov. 22
" 27,213. Chem. Fabr. vorm. Weiler-ter-Meer. Manufacture of black sulphurised dyestuffs. [Ger Appl., Dec. 5, 1905.]* Nov. 29.
" 27,322. Ransford (Cassella und Co.). Manufacture of diacetyldiaminophenol and of dyestuffs therefrom. Nov. 30

[C.S.] 2797 (1906). Imray (Meister, Lucius, und Brüning). Manufacture of pure Bordeaux-red sulphurised dyestuffs. Dec. 5.
,, 3506 (1906). Hirschberger, Hoffa, and Levinstein, Ltd. New colouring matter and the production thereof. Dec. 5.
,, 5245 (1906). Ransford (Cassella und Co.). Manufacture of polyazo dyestuffs. Nov. 28.
,, 6374 (1906). Newton (Bayer und Co.). Manufacture of new disazo dyestuffs. Nov. 28.
,, 8066 (1906). Chem. Fabr. vorm. Weiler-ter-Meer. Manufacture of new sulphur dyestuff compounds. Dec. 5.
,, 9774 (1906). Imray (Meister, Lucius, und Brüning). Manufacture of phenylglycin or its homologues. Nov. 28.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 26,125. Philip and Macintyre. Degumming certain fibres. Nov. 19.
,, 26,126. Philip and Macintyre. Process of degumming fibres. Nov. 19.
,, 26,526. Clerc-Renaud. Method and apparatus for treating textile fabrics. [Fr. Appl., Dec. 28, 1905.]* Nov. 22.
,, 26,843. Hey, Smith, Mitchell, and Askham. Apparatus for washing, impregnating, drying, or extracting liquids from fabrics and other goods. Nov. 26.
,, 26,954. Kaisser and Riche. Apparatus for torrefying threads and textile fabrics. [Belg. Appl., Nov. 28, 1905.]* Nov. 27.
,, 27,047. Holt. Apparatus for wringing or squeezing used in bleaching, dyeing, and washing fabrics. Nov. 28.
,, 27,072. Fulton and Hardcastle. Extraction of grease or oleaginous gum or resinous matter from textiles, wool, sawdust, wood shavings, &c. Nov. 28.
,, 27,128. Kaisser. Apparatus for torrifying thread and textile fabrics.* Nov. 28.
[C.S.] 3709 (1906). Kay and McGregor. Printing textile fabrics. Nov. 28.
,, 5246 (1906). Ransford (Cassella und Co.). Production of easily dischargeable claret shades on cotton goods. Nov. 28.
,, 16,908 (1906). Kalle und Co. Production of red dyeing on fibre. Nov. 28.
,, 17,163 (1906). Kalle und Co. Dyeing and printing red on textile fibre. Nov. 28.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 9830A. Garroway. Preparation of hyposulphurous acid or its salts as a bleaching agent.* Nov. 23.
,, 26,223. Grossmann. Treatment of ammonia liquors. Nov. 20.
,, 26,319. Tully. Manufacture of sulphate of ammonia. Nov. 21.
,, 26,808. Frank. Production of pure hydrogen. [Ger. Appl., Nov. 28, 1905.]* Nov. 26.
,, 26,928. Frank. Production of pure hydrogen from water-gas. [Ger. Appl., March 7, 1906.]* Nov. 27.
,, 27,006. Moscicki. *See under* XI.
,, 27,290. Cie. des Prod. Chim. d'Alais et de la Camargue. Removing silica from aluminate of soda in the manufacture of alumina. [Fr. Appl., Aug. 13, 1906.]* Nov. 30.
,, 27,316. Flügge. Manufacture of ferrous carbonate in the cold. [Ger. Appl., Nov. 30, 1905.]* Nov. 30.
C.S.] 16,681 (1905). Craig. Apparatus for producing ozone from oxygen or air. Nov. 28.
,, 24,840A (1905). Clarke, Chapman & Co., and Robson. Absorbers for ammonia. Dec. 5.
,, 16,612 (1906). Heinrici. Preparation of a stable solution of hydrogen peroxide. Dec. 5.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 27,034. Gaved. Dry process of extracting china clay, mica and quartz from decomposed granite. Nov. 28.
,, 27,048. Zahn. Process and stove for burning objects to be enamelled. [Ger. Appl., Nov. 28, 1905.]* Nov. 28.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 26,150. Von Radlovski. Burning and calcining lime, cement, chemicals, &c., in a rotable pipe kiln.* Nov. 19.
,, 26,755. Boult (Raithel). Gypsum burning kilns. Nov. 24.
,, 27,059. Hooke. Process of calcining the raw material for manufacturing cement.* Nov. 28.
,, 27,137. Turns. Manufacture of Portland cement and the like. Nov. 29.
,, 27,194. Thompson (Ahrendts). Manufacture of bricks, building blocks, or artificial stone. Nov. 29.
[C.S.] 23,816 (1905). Peters. Manufacture of Portland cement. Nov. 28.
,, 24,219 (1905). Gardeur. Manufacture of artificial sandstone. Dec. 5.
,, 24,224 (1905). Klinge and Schourup. Manufacture of artificial stones and similar building materials. Dec. 5.
,, 14,233 (1906). Liebold, Wittig, and Grimm. Manufacture of cement. Dec. 5.
,, 15,553 (1906). Schoügaard. Manufacture of artificial marble. Dec. 5.

X.—METALLURGY.

[A.] 26,202. Powell. Manufacture of steel. Nov. 19.
,, 26,284. Wheatley. Manufacture of a metallic alloy. Nov. 20.
,, 26,311. Rübel. Manufacture of metallic alloys.* Nov. 20.
,, 26,317. Auchinachie. Manufacture of an alloy of vanadium-iron or steel. Nov. 20.
,, 26,664 and 26,665. Hadfield. Manufacture of magnetic material. Nov. 23.
,, 26,882. Brown. *See under* II.
,, 26,934. Baker. Treatment of complex sulphide ores. Nov. 27.
,, 27,120. Jumau. *See under* XI.
,, 27,209. Muller and Baraduc. Production of metals, alloys, and metallic compounds such as silicides. [Fr. Appl., Nov. 29, 1905.]* Nov. 29.
[C.S.] 24,238 (1905). Ogle. Treatment of complex ores (sulphides) containing copper, zinc and lead. Dec. 5.
,, 25,004 (1905). Brayshaw. Process of hardening carbon steel. Dec. 5.
,, 10,097 (1906). Frick. *See under* XI.
,, 13,033 (1906). Dymond (Gathmann). Armour plate. Nov. 28.
,, 18,080 (1906). Ramen. *See under* XI.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 26,212. Cowper-Coles. Anodes for electro-deposition. Nov. 19.
,, 26,867. British Thomson-Houston Co. (General Electric Co.). Electric furnaces. Nov. 26.
,, 26,929. Roach. Electric furnaces.* Nov. 27.
,, 26,981. Reynolds. Electric furnaces. Nov. 27.
,, 27,006. Moscicki. Apparatus for producing oxides of nitrogen by the electric process. [Swiss Appl., Aug. 8, 1906.]* Nov. 27.
,, 27,120. Jumau. Electro-metallurgical process for extracting copper from its ores. [Fr. Appl., Nov. 29, 1905.]* Nov. 28.

[A.] 27,215. Marino and Barton-Wright. Agglutinant for consolidating the active material of accumulators.* Nov. 29.
„ 27,420. Reynolds. Electrical heating apparatus. Dec. 1.
„ 27,421. Reynolds. Method and apparatus for electrical heating. Dec. 1.
[C.S.] 4336 (1906). Bingham. Electric furnaces. Nov. 28.
„ 4684 (1906). Cowper-Coles. Production of electrotypes. Nov. 28.
„ 10,097 (1906). Frick. Method and plant for the reduction of ores and the like by electric transformer furnaces. Dec. 5.
„ 18,080 (1906). Ramen. Method of precipitating metals electrolytically. Dec. 5.
„ 18,599 (1906). Pauling. Production of arcs for the electrical treatment of gases. Dec. 5.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

[A.] 26,886. Williams. Conversion of liquid fats into solids and reduction of unsaturated organic liquids and solids. Nov. 27.
„ 27,072. Fulton and Hardcastle. *See under* V.
„ 27,280. Bacon. Manufacture of soap. Nov. 30.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(*B.*)—Resins, Varnishes.

[A.] 26,593. Schmidt. Linoleum.* Nov. 23.
„ 27,072. Fulton and Hardcastle. *See under* V.
[C.S.] 24,622 (1905). Kershaw. Elastic material or plastic compound suitable for varnishes, &c. Nov. 28.
„ 15,338 (1906). Justice (McKenzie). Extraction of turpentine and other products from wood. Dec. 5.

(*C.*)—India-Rubber.

[C.S.] 24,622 (1905). Kershaw. *See under* XIII*B.*
„ 6183 (1906). Granier and Froger-Delapierre. Compound for coating caoutchouc to preserve its natural properties. Dec. 5.
„ 10,704 (1906). Roland. Elastic substance similar to india-rubber. Nov. 28.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

[A.] 26,188. Howorth (Oesterreich. Pluviusin A.-G.). Manufacture of imitation chamois leather.* Nov. 19.
„ 26,555. Fontana. Process for removing colouring materials from tanning liquors. Nov. 23.
„ 26,673. Lambert. Liquid for use in melting and diluting glue. Nov. 24.
[C.S.] 25,467 (1905). Inrig. Treatment of waste leather. Nov. 28.

XV.—MANURES, &c.

[A.] 26,635. Bazin. Increasing the quantity of nitrogen in peat, with a view to its employment as manure. [Fr. Appl., Dec. 14, 1905.]* Nov. 23.
„ 26,790. Colburn. Treatment of animal and vegetable matter for the production of manure. Nov. 26.

XVI.—SUGAR, STARCH, GUM, &c.

[A.] 26,871. Newton-Clare. Manufacture of sugars. Nov. 26.

XVII.—BREWING, WINES, SPIRITS, &c.

[A.] 26,169. Sleeman. Apparatus for washing, steeping, aërating, and germinating grain. Nov. 19.
„ 26,689. Frestadius. Production of alcohols from peat. Nov. 24.
[A.] 27,343. Bailey. Conversion machine and processes for use by brewers. Dec. 1.
[C.S.] 24,739 (1905). Pollak. Production of ferments and fermented materials. Dec. 5.
„ 37 (1906). Tonnaer and De Keersmaecker. Fermenting vats for use in making beer. Nov. 28.
„ 12,838 (1906). Bergo and Kainscop. Process of manufacturing beer. Nov. 28.
„ 13,915 (1906). Schalk. Fermenting wort. Nov. 28.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(*A.*)—Foods.

[A.] 27,041. Fuglistaller. Manufacture of chocolate. Nov. 28.
„ 27,153. Kurz. Process for preserving meats.* Nov. 29.
[C.S.] 6389 (1906). Little. Bleaching or conditioning flour or other ground cereal. Nov. 28.

(*B.*)—Sanitation; Water Purification.

[C.S.] 19,214 (1905). Wixford. Process and system for purifying water. Dec. 5.
„ 19,215 (1905). Wixford. Process of purifying water. Dec. 5.

(*C.*)—Disinfectants.

[C.S.] 24,618 (1905). England. Antiseptic or disinfecting compounds. Dec. 5.

XIX.—PAPER, PASTEBOARD, &c.

[A.] 26,501. Lederer. Process for obtaining cellulose esters from solutions. Nov. 22.
„ 26,502. Lederer. Preparation of acidylised cellulose solutions. Nov. 22.
„ 26,503. Lederer. Cellulose compounds or compositions. Nov. 22.
„ 26,944. Pering. Machine for making washable fat- and water-proof paper in the cold way.* Nov. 27.
„ 26,962. Beck. Manufacture of paper, paperboard, and moulded products.* Nov. 27.
„ 27,125. Beck. Apparatus for making half-stuff from peat turf.* Nov. 28.
„ 27,126. Beck. Apparatus for making half-stuff from peat.* Nov. 28.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

[A.] 23,648A. Newton (Bayer und Co.). Manufacture of mono-iodobehenic acid. Nov. 19.
„ 26,689. Frestadius. *See under* XVII.
„ 26,838. Johnson (Verein. Chininfabr. Zimmer und Co.). Manufacture of a new pharmaceutical product. Nov. 26.
[C.S.] 5032 (1906). Weizmann, and Clayton Aniline Co. Manufacture of camphene. Nov. 28.
„ 5039 (1906). Abel (Act.-Ges. f. Anilinfabr.). New salts of hexamethyleneamine and the manufacture thereof. Dec. 5.
„ 8527 (1906). Johnson (Verein. Chininfabr. Zimmer und Co.). Manufacture of quinine oxymagnesium haloid compounds and of quinine esters therefrom. Dec. 5.
„ 19,960 (1906). Basler Chem. Fabr. Manufacture of camphene. Nov. 28.

XXII.—EXPLOSIVES, MATCHES, &c.

[C.S.] 6581 (1906). Nathan, Thomson, Rintoul, and Scott. Manufacture of nitroglycerine. Dec. 5.
„ 17,414 (1906). Reschke. Manufacture of safety explosives. Nov. 28.

London Section.

Meeting held at Burlington House, on Monday, November 3, 1906.

MR. R. J. FRISWELL IN THE CHAIR.

THE ALLEN-MARQUARDT PROCESS FOR THE ESTIMATION OF HIGHER ALCOHOLS.*

BY E. A. MANN AND C. E. STACY.

IN the course of an extended investigation of samples of whisky for the Western Australian Government, in which the Allen-Marquardt method was employed for the estimation of higher alcohols, certain results were obtained which led us to make a special examination of this process. The method was used exactly as described by Allen and Chattaway (Analyst, Vol. XVI.). In sub-tropical countries like Western Australia we are doubtless confronted with difficulties in chemical processes which never occur to workers in colder climates, and this occurred in the present instance.

We had been engaged for six months in examining a large number of samples of whisky, which were worked off in batches of 10 each. The examination was begun in early winter (June) and concluded in the middle of summer (the following January). Early in December, when the first severe heat of summer began to make itself felt, discrepancies began to appear in our estimations of the higher alcohols. Very much higher proportions of these constituents appeared than the rest of the analysis would have led us to expect, and we naturally looked to the climatic conditions for an explanation. In winter the laboratory temperature frequently falls as low as 50° F., while in summer it frequently rises to 96°—98° F.† One series of tests was specially designed to investigate the influence (if any) of these temperatures upon the process. The other series of tests was made with a view to studying the end reactions obtained in the final titration with barium hydroxide, and especially as to the necessity and desirability of the preliminary titration with methyl orange for mineral acids.

Influence of temperature.—In cases where the higher alcohols had been extracted with carbon tetrachloride during high summer temperatures, we obtained very low combining weights for the acids contained in the final barium salts, in other words, large proportions of acetic acid were present with the valeric acid. This indicated that, at the higher temperatures, the ethyl alcohol was dissolved in the tetrachloride to an increased extent.

This suggested the following questions:—(1) Were the higher alcohols completely extracted under these circumstances? (2) Was the amount of ethyl alcohol dissolved affected by and proportional to the temperature? (3) How could a correction be made for the error thus introduced in the final titration.

In order to test the first question pure alcohol had to be prepared, and known quantities of higher alcohols added.

Preparation of pure alcohol.—About two litres of commercial absolute alcohol were taken, sufficient concentrated alkali solution added to neutralise acids and saponify esters, and the whole boiled under a rectifying column for half an hour without, however, allowing any to distil over. Seventy-five c.c. were then distilled off very slowly (about one drop every two seconds) and rejected; a further 750 c.c. was then collected at the rate of about one drop per second. This distillate was diluted to a strength of 15·6 under proof—and used for the subsequent tests.

Addition of higher alcohols.—To 700 c.c. of the diluted pure alcohol was added 0·777 grm. of amyl alcohol giving 0·111 grm. per 100 c.c. The amyl alcohol used was Merck's "*purissimum*," boiling between 128° and 131° C. It was enclosed in a small, specially-blown glass bulb, previously tared, which was sealed off before weighing; the bulb was then broken after immersion in the ethyl alcohol.

Three lots of 100 c.c. of pure alcohol were shaken out, oxidised, and titrated according to Allen and Chattaway's method. The laboratory temperatures during the shaking out gradually rose from 86° to 92° F.

TABLE I.—*Tests on pure alcohol.*

Test.	1.	2.	3.
Barium hydroxide required for mineral acid	1·6	1·6	1·6
Barium hydroxide required for mineral acid in organic acid	14·7	15·4	14·9
Equivalent to amyl alcohol per 100 c.c. (in grms.)	0·1294	0·1355	0·1311

These results seemed extraordinarily high for purified ethyl alcohol, and we therefore took the combining weight of the acids in the barium salt obtained, and found, as we supposed, that the greater portion of the acid was acetic acid. In all cases, therefore, the true amount of valeric acid was arrived at by calculation.* The above three results then became:—

TABLE No. 2.

	Volume of *N*/10 barium hydroxide used.	Equivalent amyl alcohol by direct reading.	Weight of barium salts, less barium chloride.	Combining weight of mixed acids.	Calculated barium acetate.	Calculated barium valerate.	True amyl alcohol.	Grms. per 100 litres of absolute alcohol.
	c.c.							
1	14·7	0·1294	0·1959	65·7	0·1615	0·0344	0·0178	36·96
2	15·4	0·1355	0·2077	67·4	0·1618	0·0459	0·0238	49·60
3	14·9	0·1311	0·1985	65·7	0·1640	0·0345	0·0179	37·14

From this it would appear that even the carefully-prepared ethyl alcohol contained quite notable quantities of higher alcohols. This, however, was largely corrected by subsequent investigations.

Three lots of 100 c.c. of the control amyl alcohol solution were then treated in similar manner. The titration of these gave inflated figures for amyl alcohol in the same way as the pure alcohol solutions, but, when checked by the combining weight determination, the following results were obtained:—

* By the following formula $x = \frac{W - w}{1{\cdot}329} - 1$

Where x = acetate of barium in mixed salts; W = barium hydroxide used in titration (in grms.) calculated to barium valerate; w = Weight of mixed acetate and valerate of barium found. 1·329 = ratio of molecular weights of barium acetate and barium valerate.

* This paper was received in June last, just after the last meeting of the Session 1905-1906, and was taken as read.

† A temperature of 100° F. has been recorded on one occasion in the laboratory during last summer.

TABLE No. 3.

4	22·9	0·2015	0·3272	84·4	0·1184	0·2188	0·1099	228·11
5	22·6	0·1989	0·3217	79·4	0·1496	0·1721	0·0893	195·36
6	23·8	0·2094	0·3540	81·2	0·1496	0·2044	0·1061	220·22

The amyl alcohol found in each case was, therefore, considerably less than that taken. As we expected, at these high temperatures, considerable quantities of ethyl alcohol were removed by the tetrachloride in the shaking out—also apparently the extraction of amyl alcohol was not quite, though nearly complete. Considering the great difference effected in a result by a very small error in the determination of the combining weight (*vide infra*), we think that some at least of the discrepancies are due to slight errors introduced into the combining weight determination through the presence of large quantities of barium acetate.

The above experiments were under actual working temperature conditions; it now became necessary to compare the results with those obtained at low temperatures. The use of ice to cool the solutions while shaking out was not found satisfactory in reducing the working temperatures, as it was found difficult by this means to maintain uniform conditions. Arrangements were therefore made to carry out the extractions with tetrachloride for a series of tests in a refrigerating chamber. Through the courtesy of the manager of the Government Refrigerating Works, a room was placed at our disposal at which a uniform temperature of 60° F. was maintained. The solutions, previously prepared, and the required apparatus and reagents were transferred to this chamber, and allowed to acquire the temperature of the air before any shaking out was attempted—the processes were then carried out as usual, and the separated tetrachloride containing the higher alcohols was returned to the laboratory for oxidisation and the subsequent manipulation. Six tests corresponding precisely to those described above were carried out with the following results. Nos. 7, 8 and 9 were made with pure ethyl alcohol. Nos. 10, 11, and 12 with solutions containing 0·111 grms. of amyl alcohol per 100 c.c.:—

TABLE No. 4.—*Tests at temperature of* 60° *F.*

9	3·5	0·0308	0·0494	73·6	0·0300	0·0194	0·0100	20·67
10.	12·6	0·1109	0·1968	88·7	0·0534	0·0484	0·0744	154·35
11.	11·9	0·1047	0·1925	94·3	0·0276	0·1049	0·0856	177·65
12.	12·0	0·1076	0·1906	91·5	0·0386	0·152	0·0789	163·81

The following points were at once suggested:—

1. That the ethyl alcohol apparently goes into solution in the tetrachloride to a much smaller extent at the lower temperature, and consequently much less acetic acid is obtained on oxidation, but that nevertheless titration alone cannot be relied upon; in all cases the combining weights of the organic acids must be determined, and the amount of valeric acid calculated therefrom.*

2. That the figures for the "purified" ethyl alcohol show a much smaller proportion of higher alcohols, *i.e.*, that little, if any, of these bodies remains in the purified spirit, as we expected. The difference between the tests 1, 2, and 3, and 7, 8, and 9 in this respect, is, we believe, due to the presence of the larger proportion of barium acetate present in the first three tests, which tends to introduce slight errors and magnify the effect of those errors in the determination of the combining weights.

3. The extraction in tests 10, 11, and 12 is again considerably below the theoretical.

The first two of these conclusions confirmed our expectations. The third called for further inquiry. This, however, was conducted in connection with the other series of experiments already referred to, and these will first be described.

Experiments with regard to the titration.—At an early stage of our work we became convinced that the preliminary titration "for mineral acids," using methyl orange as an indicator, was not reliable, because the methyl orange was sensibly affected by fatty acids. Thus acetic acid gives an acid reaction with methyl orange which is not quantitative. Even after a titration with barium hydroxide has been conducted to distinct alkalinity with methyl orange, a considerable amount of acidity is disclosed by the further addition of phenolphthalein. The following tests illustrated this:—Four solutions of acetic acid in distilled water were prepared containing respectively (13) 0·03012 grm., (14) 0·06024 grm., (15) 0·09036 grm., (16) 0·12048 grm. of acetic acid in 100 c.c. These were titrated with *N*/10 barium hydroxide using methyl orange, and the neutral and distinctly alkaline points noted. The titration was then continued to the end point with phenolphthalein. The amounts of *N*/10 barium hydroxide required to titrate acetic acid were:—

TABLE No.

Test.	Methyl Orange neutral point c.c.	Distinct alkalinity c.c.	Phenolphthalein end reaction c.c.
13	0·6	0·9	4·9
14	1·6	2·0	9·8
15	2·7	3·9	14·7
16	3·9	5·0	19·6

* This latter conclusion, however, was found to be fallacious.

It is therefore evident that the use of methyl orange is inadmissible when acetic acid is present.*

We then proceeded to inquire what was the probability of the formation of mineral acid in the process, and whether the preliminary titration for these acids should not be entirely dispensed with. Three lots of 100 c.c. of carbon tetrachloride were treated with the usual amount of oxidising mixture, and in exactly the same way as in an estimation of higher alcohols, except that, of course, no ethyl alcohol was present. The distillate obtained after oxidation gave no reaction whatever with methyl orange, so that no mineral acids were present as the result of the oxidising mixture alone or from action upon the tetrachloride. In one case, however, the first two drops of methyl orange were *bleached* and chlorine could be detected by smell; traces of this substance could also be detected by smell in the residues of the other two tests. This bleaching of methyl orange has been noticed in a number of cases where potable spirits have been examined, and may be due to (1) decomposition of carbon tetrachloride†; (2) oxidation of chlorides, present as impurities in the oxidising mixture; or (3) introduction of chlorine compounds in the sample in the case of potable spirits.

Three extractions (each with 100 c.c. of tetrachloride) were then carried out precisely as in the Allen-Marquardt process, in all respects except that alcohol was absent. That is to say, the shaking with salt solution, and subsequent washing with saturated salt and sodium sulphate solutions, was applied in each case, and then the oxidation again carried out as in the last three tests. Again no action on the indicator (except slight bleaching) was discernible on adding methyl orange; the smell of chlorine was again detected. It would appear therefore that no mineral acids are formed in the process or from the materials used.

The following table gives the results of tests Nos. 1 to 12 recalculated so that no deduction is made for mineral acid, but all acidity is taken as organic acid:—

* *Vide* also Sutton—"Volumetric Analysis," and Biedemann, Chem. Kal., 1906.

† Throughout the experiments pure carbon tetrachloride prepared by Merck, specially procured from Europe, was employed.

It was now possible (since the action on mineral acids had been eliminated) to test the action of valeric acid on methyl orange. This was done as follows:—Pure amylic alcohol (b. pt. 128°—131°) was added in the following respective amounts to three portions of carbon tetrachloride:—(23) 0·0383 grm., (24) 0·0677 grm., (25) 0·1360 grm. These solutions were oxidised and titrated with both indicators, as in the case of experiments Nos. 1—4, with the following results:—

TABLE No. 7.

N/10 *Barium hydroxide required to titrate valeric acid.*

No.	Methyl Orange.		Phenolphthalein.		
	Neutral c.c.	Alkaline c.c.	End reaction c.c.	Equal to amyl alcohol.	Difference from theoretical.
23	0·4	0·6	4·6	0·0401	0·0018
24	0·6	0·9	7·2	0·0634	0·0047
25	1·0	1·5	16·0	0·1408	0·0152

It is evident, therefore (as was of course to be expected), that valeric as well as acetic acid effects methyl orange. In the last two tests it will be noticed that apparently a considerable loss of amyl alcohol occurs, equal to 10 and 31 grms. respectively in 100 litres of absolute alcohol, and this loss, apparent in tests 1—12, has already been referred to in connection with the first series of tests. This was further investigated. The residues from the final distillation (after oxidation) in tests 24 and 25 were diluted and again distilled. The distillates, when titrated required 0·1 c.c. and 0·2 c.c. *N*/10 barium hydroxide solution respectively. The corks used during the oxidation* were boiled, and the solutions obtained in each case took a further 0·1 c.c. of alkali. These figures give a further yield of 0·00176 grm. and 0·00264 grm. of amyl

* All corks used throughout the process were protected with tin foil.

alcohol respectively. The loss could not therefore be accounted for in these directions. In case the error might be due to impurities in the amyl alcohol used, that employed in the previous tests was refractionated, and only that portion boiling between 129·5° and 130° C. was used for a further series of tests.

Tests 26 to 35—ten lots (each 100 c.c.) of purified ethyl alcohol were diluted to 15° under proof, and amyl alcohol added so that the first five solutions contained 0·0867 grm., and the second five 0·04906 grm. They were then salted out and extracted in the usual way, except that two successive washings of 40 c.c. of tetrachloride solution were used, and then the usual washings of 30, 20, and 10 c.c., making 140 c.c. of tetrachloride in all.* The end titration was made with phenolphthalein alone, and the total acidity reckoned as organic acids. In other respects the process was conducted in exactly the usual way. The room temperatures during the tests varied from 68°—74° F. The results are given in Table No. 8.

loss in others, trifling, in fact, as compared with the loss when oxidation was conducted under a reflux condenser. After titration, the carbon tetrachloride was separated from the aqueous solution of barium valerate, the flask and separator washed, and the washings added to the aqueous solution, which was evaporated in large platinum dishes to dryness, and the residues further dried for one hour at 100° C. In no case was the theoretical amount of barium valerate obtained, and in most cases the loss was very serious. In one experiment, a weighed quantity of barium carbonate was added to the solution during evaporation, to see if this would prevent loss of valeric acid, but without result.

In any attempt to correct the titration result in the Allen-Marquardt method, when, by reason of the temperature of "shaking out," acetic acid may be present, it is obvious that this loss of valeric acid, by lowering the apparent combining weight of the organic acids, will introduce a grave error. Thus, taking the maximum loss in the present series of experiments (test No. 43), the

						Average	loss of amyl	alcohol ..	25·40	

It will be seen that a loss occurred in all cases, which has been calculated into grms. per 100 litres of absolute alcohol. The original alcoholic strengths of the solutions were those of ordinary bottled commercial spirits, and therefore the loss is that which might be expected in the examination of such spirits. The average loss is more than half the maximum, and more than twice the minimum. The uniform amount of ethyl alcohol extracted in these tests as shown in column 6 is particularly interesting.

It has been pointed out by Schidrowitz (Analyst, **30**, p. 191) that some loss is incurred through the incomplete condensation of tetrachloride containing valeric acid in the reflux condensers used during the oxidation process, and he recommends the use of special rod and disc condensers and ground in glass connections. These were not procurable here, so we made experiments with the oxidation process carried on in pressure bottles. The results of these were so satisfactory that in future we intend to use this apparatus in preference to reflux condensers. The method has also the great advantage of saving at least half the time in oxidation, though it requires more personal attention on the part of the analyst.

Tests in closed bottles.—Thirteen tests with varying quantities of pure amyl alcohol dissolved in purified carbon tetrachloride were carried out. The tests were enclosed in 8 oz. flat stoppered bottles, clamped in specially prepared brass frames. They were heated for four hours in a water oven, at a temperature of about 96° C., and were shaken for one minute about every seven minutes. From the annexed table it will be seen that, by direct titration, there was no loss in some cases, and very slight

* This precaution was taken to see if any further extraction of amyl alcohol occurred. The results showed that no such effect

theoretical amount of barium valerate was 0·161 grm., but the actual weight of barium valerate obtained was only 0·1468 grm.*; the difference, 0·0142 grm., indicates *directly* a loss of 0·007 grm. of amyl alcohol; this difference however, also increases the apparent amount of barium acetate present, and taking into account the lowering effect of this upon the combining weight, it represents a loss of 0·0298 grm. of amyl alcohol or a total of 0·0836 grm. as found by titration. The error thus introduced is described in the appended table as "working error," while the direct error is shown in column 5.

48	0·1040	0·1047	0·0763	0·007	0·0284

* The [illegible] figures not shown in the table.

The loss in the reflux condenser would appear therefore to be a very serious and constant one, as pointed out by Schidrowitz; but a still more serious one appears to have been overlooked, viz., that due to the loss of valeric acid by evaporation from the barium salt during the estimation of the combining weight. This error is so great that in our opinion it entirely vitiates the value of this operation.

A peculiar circumstance was noticed during these special tests, which we have not seen previously recorded. In all cases where the amount of amyl alcohol acted upon approached 0·1 grm., a heavy precipitate was produced during the oxidation. In the subsequent distillation, at the point when the last tetrachloride was boiled off a heavy, dry looking scum formed in the distilling flask, and only disappeared when the remaining aqueous liquid, had boiled for some little time. Only in one case during the analysis of over 100 samples of commercial spirits was this effect observed, and that was a case where the higher alcohols were present in exceptionally large quantities.

Although the conclusions arrived at may appear in some instances to be based on a very small series of tests, we would like to say that in every instance the results of these special series have been confirmed by others obtained in a very extensive examination recently made in the laboratory, embracing 105 different brands of commercial spirits.

Conclusions.

1. In order to obtain complete oxidation of the amyl alcohol and recovery of the valeric acid, the pressure bottle method is preferable to the use of reflux condensers.

2. Serious loss of valeric acid occurs in the process of drying the barium salts for estimation of the combining weight of the acid.

3. At temperatures exceeding 60° F., the solubility of ethyl alcohol in carbon tetrachloride, and subsequent formation of acetic acid during oxidation, render it impossible to calculate the higher alcohols from the titration alone; this solubility increases with the working temperature.

4. The titration for mineral acids is unnecessary, and introduces errors.

5. Accurate results may be obtained by observing the following points:—

(*a*) The shaking out to be performed at a temperature of 60° F., or less.

(*b*) The oxidation to be conducted in pressure bottles.

(*c*) The higher alcohols to be determined by *direct titration* only, calculating all acidity as valeric acid.

BY F. G. TROBRIDGE.

Communicated by Professor Bedson.

This note sets forth the results of the analysis of the gases enclosed in the coal constituting the Busty Seam, at Birtley, in the County of Durham, together with the examination of the gases enclosed in the dust formed in the screening of the coal, and in samples of dust collected on the timbers in the mine. The samples were supplied by Mr. Philip Kirkup, who also kindly gave a section of the seam, showing the relative proportions of bright coal and "dant" which constitute this seam.*

The method of extracting the gases from the coal is practically that adopted by W. J. Thomas. A weighed amount of the coal or dust contained in a round bottomed flask is sealed on to a mercury air-pump, *e.g.*, either a Töpler or Geissler pump. The air was removed in the usual manner, and in establishing a vacuum the last portion of air was collected, and analysed. The coal was now allowed to remain in the exhausted flask, &c., for several days, the gas evolved being pumped off from time to time, collected over mercury, and subsequently analysed. After removal of these gases the coal was next heated for several hours by means of water kept boiling, the gas so driven off was pumped off, collected, measured, and analysed. This procedure was repeated until it was judged that the whole of the gas obtainable under these conditions had been expelled.

The gases obtained in this manner were analysed, the apparatus devised by Dr. Sodeau being used for this purpose.

The following table contains a statement of the results:—

	Bright coal.	"Dant."	Surface dust.	Dust from timbers.
Weight of coal ..	296 grms	246 grms.	156 grms.	201·0 grms.

Although the investigations of von Meyer, W. J. Thomas, Bedson, and McConnell, Dr. Brookmann, the Reports of the Fire-Damp Commissions in Prussia and Austria, &c., have made us familiar with the general character of the gases enclosed in coal and coal dust, there are still some points of interest brought to light in the analyses detailed above. In the first place, it is evident that the bright coal is mainly responsible for the occluded gases in a sample of coal, yielding not only the larger volume, but also the larger proportion of combustible gas. Further, the results of the explosion of the combustible gas show this constituent to be almost entirely marsh gas, as is that from the "dant" also; whereas the combustible gas yielded by the dust formed in screening the coal gives results which are most easily interpreted as indicating the presence with marsh gas of other hydrocarbons of the paraffin series; although this indication is not so marked as that obtained by Bedson in his examination of the gases obtained from the dust produced in the screening of coal at Ryhope, and communicated to the North of England Mining Institution in 1888. The presence of the higher homologues of marsh gas in similar dusts has also been drawn attention to in the Report of the Austrian Fire Damp Commission.

The proportion of oxygen in the last portion of air removed in the evacuation of the vessels containing the coal calls for remark. It will be noted that its proportion to the nitrogen is greater than in air. This confirms an observation described by Bedson (Trans. of Federated Institution of Mining Engineers, 1902), in which pieces of freshly hewn coal were let up into the Torricellian vacuum of a specially constructed barometer; and the gases given off removed and analysed. Coal of the same origin was, after being exposed to the air of the laboratory, treated in a similar manner. The analysis of the gases obtained in this way gave the following results:—

	Freshly hewn coal.	Coal after exposure to the air.
Carbon dioxide ..	1·65	1·18
Oxygen	8·79	23·80
Marsh gas	44·60	3·58
Nitrogen	44·76	71·44
	100·00	100·00

showing that coal, after removal from the mine, not only gives off its "enclosed gases," but takes up gases from the air and oxygen preferentially to nitrogen.

Attention is being directed to the nitrogen contained in the occluded gases, with the object of ascertaining the presence or otherwise of the inert gases, which are associated with atmospheric nitrogen. As the experiments are still in progress it has not been thought desirable to include an account of these in this note.

A similar examination has been made of the occluded gases in a sample of coal dust from the Fernie Mine in British Columbia, where an explosion occurred in 1902. The sample of dust (remarkable for its fineness), and also of the coal from the same mine were obtained by Dr. Bedson from Mr. J. Ashworth, Mining Engineer, Derby, England.

The gases differ from those of the Busty seam, in character of the combustible constituents, which are undoubtedly mixtures of higher homologues of the marsh gas series. In fact, the composition of these gases is not dissimilar to that of the gases obtained by Bedson (*loc. cit.*) from the Ryhope coal dust and coal.

The following table contains the results of the analyses of the occluded gases:—

Fernie coal.

	Vol. from 100 grms. coal.	Carb. diox.	Oxygen.	C_nH_{2n}.	Carbon monoxide.	C_nH_{2n+2}.	Nitrogen.
Coal Dust—	c.c						
(*a*) Gas at ordinary temperature	12·8	25·5	9·7	0·0	0·0	5·3	59·5
(*b*) Gas at 100° C.	16·2	36·7	11·7	0·0	0·0	10·8	40·6
Coal—							
(*c*) Last portion of air	—	7·5	10·6	0·0	0·0	8·6	73·3
(*d*) Gas at ordinary temperature	22·2	16·5	7·2	0·0	0·9	24·3	57·1
(*e*) Gas at 100° C.	23·1	35·4	1·0	0·4	7·9	52·7	2·6

The results of the explosion of the combustible constituents of these gases, gave the following values for "n" in the formula C_nH_{2n+2}, in "*a*" n = (approximately) 1, in "*b*," n = 4·4, in "*c*," n = 2·1, in "*d*," n = 1·8, and in "*e*," 2·5.

Scottish Section.

Meeting held at Glasgow on Friday, November 9, 1906.

PROF. THOMAS GRAY IN THE CHAIR.

THE MANUFACTURE OF CYANOGEN BROMIDE.

BY THOMAS EWAN, M.SC., PH.D.

The use of cyanogen bromide as a solvent for gold was first proposed by Dr. Gaze, of Westport, New Zealand, in 1892, shortly after the introduction of the cyanide process of gold extraction. Sulman and Teed in 1894 showed that it was only efficient as a solvent for gold when used with an alkali cyanide, its function being the same as that of oxygen in the solution. The greater rapidity of extraction which may be obtained by the use of cyanogen bromide does not, as a rule, make up for the extra cost of the reagent, and its use is therefore limited to a few refractory ores which cannot be treated satisfactorily by cyanide alone.

Before the introduction of Sulman and Teed's process cyanogen bromide was made by adding a solution of a cyanide to bromine, thus, $Br_2 + KCN = KBr + BrCN$. It was soon found, however, that cyanogen bromide itself polymerises much too readily to permit of its transport,

more especially through tropical latitudes. Similar difficulties in the case of bromine led to the introduction of two new processes of manufacture, which were described by C. Göpner in 1901 (Zeits. angew. Chem., 1901, 355). In the first of these dilute sulphuric acid was added to a solution containing sodium bromide, bromate, and cyanide in the proportions $5NaBr + NaBrO_3 + 3NaCN$ at 70° C., the cyanogen bromide produced distilling over. In this process only one-half of the bromine is obtained in the form of cyanogen bromide. The second process, which is that now employed, avoids the loss of bromine by using a larger quantity of bromate, the reaction being $2NaBr + NaBrO_3 + 3NaCN + 3H_2SO_4 = 3BrCN + 3Na_2SO_4 + 3H_2O$.

The reaction of bromic and hydrobromic acids was studied by Judson and Walker (J. Chem. Soc., 1898, **73**, 410). They showed that it occurs in stages; the first change is a slow one represented by the equation, $2H' + Br' + BrO_3' = HBrO + HBrO_2$. This is followed by the two instantaneous changes, $HBrO + HBr = Br_2 + H_2O$ and $HBrO_2 + 3HBr = 2Br_2 + 2H_2O$. The rate at which the change proceeds is that of the first reaction and is expressed by the equation—

$$-\frac{dC_{BrO_3'}}{dt} = k\,[C_{H'}]^2\,[C_{Br'}]\,[C_{BrO_3'}] \quad \ldots\ldots 1.$$

where $C_{H'}$, $C_{Br'}$, and $C_{BrO_3'}$ are the concentrations, in gram molecules per litre, of the hydrogen, bromide, and bromate ions respectively.

Judson and Walker made two sets of measurements of the velocity of the reaction between pure bromic and hydrobromic acids in aqueous solution at 25°. The average values of k in equation (1) calculated from the results of these measurements are 285 and 309.

I made a few measurements by the method described by Judson and Walker, using a commercial "bromine salt" containing sodium bromate and bromide in the proportion $NaBrO_3$:5NaBr. The reaction was started by adding the exact quantity of hydrochloric acid required to liberate the bromic and hydrobromic acids and to neutralise a small quantity of sodium carbonate which was present in the salt. The results obtained at 25° were:—

Time in mins.	$C_{BrO_3'}$.	k.	Time in mins.	$C_{BrO_3'}$.	k.
0	0·0254	—	0	0·0127	—
3	0·0126	269	5	0·0094	273
6	0·0094	348	17	0·0068	296
15	0·0083	211			
	Average ..	276		Average ..	285

The presence of sodium chloride has, therefore, as was to be expected, no effect on the rate of the reaction. The value of k at 25° may be taken as 290.

When bromic and hydrobromic acids react in presence of hydrocyanic acid, it appears possible that in addition to the simple reaction of bromine on hydrocyanic acid, $Br_2 + HCN = HBr + BrCN$, other changes may occur. The bromous and hypobromous acids produced as intermediate products of the change might react thus, $HCN + HBrO = H_2O + BrCN$

$$3HCN + HBrO_2 = 2H_2O + BrCN + C_2N_2$$

The first of these reactions would not affect the rate of change, because it is equivalent to the reactions $HBrO + HBr = Br_2 + H_2O$ and $Br_2 + HCN = BrCN + HBr$, but the second reaction would leave hydrobromic acid in solution which would otherwise have been decomposed, and in this way would accelerate the reaction. The same would be true of the reaction $HBrO_3 + 5HCN = BrCN + 2C_2N_2 + 3H_2O$.

Measurements of the velocity of reaction were, therefore, made partly in order to clear up the mechanism of the reaction, partly to find the time required for complete reaction under various conditions.

The experiments were made as follows: The necessary quantities of sodium bromate, bromide, and cyanide were mixed in small flasks with india-rubber stoppers, diluted to the strength desired and placed in a water bath heated to 25° C. until the solutions had acquired that temperature. The quantity of hydrochloric acid required to neutralise the cyanide and to liberate the bromic and hydrobromic acids was then run in quickly, and the mixture allowed to stand at 25° for a measured time. The reaction was then stopped by adding an excess of caustic soda, which converts the cyanogen bromide into cyanate and bromide. The unchanged cyanide was then titrated with silver nitrate and potassium iodide indicator, after which the solution was acidified, excess of potassium iodide added, and the iodine liberated by the action of the unchanged bromic acid on the hydriodic acid titrated with sodium thiosulphate.

The results obtained are contained in the following tables. The initial concentration (in grm. mols. per litre) of the bromic acid is given and also the relative quantities of the other substances present in the solution. The presence of a little sodium carbonate in the salts used accounts for the extra sodium chloride present.

I.

Initial concentration of bromic acid = 0·0102 gr. mol. per litre. Composition of solution—

$$HBrO_3 + 4{\cdot}96HBr + 3{\cdot}04HCN + 9{\cdot}88NaCl.$$

Time in mins.	Per cent. of hydrocyanic acid unchanged.	Per cent. of bromic acid unchanged.	k.

IV.

Initial concentration of the bromic acid = 0·02322 gr. mol. per litre. Composition of solution—

$$HBrO_3 + 2HBr + 3HCN + 6{\cdot}11NaCl + 0{\cdot}15HCl.$$

Time in mins.	Per cent. of hydrocyanic acid unchanged.	Per cent. of bromic acid unchanged.	k.
3	83·5	83·2	316
5	78·1	80·4	264
13	62·7	64·0	344
29	45·7	51·0	254
73	35·4	38·0	322
		Average	300

The nearly constant difference between the loss of hydrocyanic acid and of bromic acid which is apparent in the above tables appears to be due to volatilisation of hydrocyanic acid. Two blank experiments, in which no bromic acid was used, gave losses of 1·3 and 2·3 per cent. of the hydrocyanic acid in 30 and 45 minutes respectively.

It is now necessary to deduce the equations for the velocity of the reactions studied; for comparison, the reaction between bromic and hydrobromic acids may also be included.

Provided that no secondary reactions occur the changes are:—

$$HBrO_3 + 5HBr + 3HCN = 3BrCN + 3HBr + 3H_2O \quad (A)$$

$$HBrO_3 + 2HBr + 3HCN = 3BrCN + 3H_2O \quad (B)$$

$$HBrO_3 + 5HBr = 3Br_2 + 3H_2O. \quad (C)$$

Regarding the strong acids as completely dissociated and the hydrocyanic acid as entirely undissociated, the concentrations of the reacting ions after t minutes, when the fraction m of the bromic acid remains unchanged, are:—

	A	B	C
$C_{BrO_3'}$	mC	mC	mC
$C_{Br'}$	$(3-2m)C$	$2mC$	$5mC$
$C_{H'}$	$(3-3m)C$	$3mC$	$6mC$

where C is the initial concentration of the bromic acid.

Substituting these values in the differential equation (1) and integrating, we obtain finally,

$$Ct = \frac{1}{27k}\left(2{\cdot}3026\log_{10}\frac{(1{\cdot}5+m)^4}{m(1+m)^3} - \frac{3}{1+m} - 0{\cdot}086\right) \quad .. (A^1)$$

$$Ct = \frac{1}{54k}\left(1-\frac{1}{m^3}\right) \quad ..... (B^1)$$

$$Ct = \frac{1}{540k}\left(1-\frac{1}{m^3}\right). \quad ..... (C^1)$$

The values of k in Tables I. and II. are calculated by means of equation A^1. Equation B^1 does not apply exactly to the figures in Tables III. and IV., because in one case there was a slight deficiency and in the other a small excess of acid. The values of k in these tables were, therefore, obtained directly from the differential equation, the values of the differential co-efficients being obtained graphically from a curve drawn through the experimental points. The values calculated by means of B^1 are, however, very little different from those obtained in this way.

The values of k, at 25°, for the three different reactions are, (A) 255 and 275, (B) 300 and 304, (C) 276 to 309; the agreement is sufficiently close to warrant the conclusion that no secondary changes of any importance occur.

Experiments with sulphuric acid.—Two experiments were made in exactly the same way as those described in Tables I. and II., except that sulphuric acid was used instead of hydrochloric acid. The results are given in Tables V. and VI., and, for comparison, the times required to reach the same stage in the change using hydrochloric acid are interpolated from Tables I. and II.

TABLE V.—*Initial concentration of bromic acid*, 0·0102 grm. mol. per litre. Composition of solution, $HBrO_3 + 4{\cdot}06HBr + 3{\cdot}04HCN + 4{\cdot}94Na_2SO_4$:—

Per cent. of hydrocyanic acid unchanged.	Time in mins.	Time with hydrochloric acid.	Ratio.

53·9	70	19·4	3·6
27·9	224	51·8	4·3
23·4	334	60·8	5·5
2·3	971	—	—

TABLE VI.—*Initial concentration of bromic acid*, 0·0204 *gr. mol. per litre.* Composition of solution, $HBrO_3 + 4{\cdot}06HBr + 3{\cdot}04HCN + 4{\cdot}94Na_2SO_4$:—

Per cent. of hydrocyanic acid unchanged.	Time in mins.	Time with hydrochloric acid	Ratio.
72·4	5	—	—
54·5	13	2·3	5·6
37·0	31	4·4	7·0
11·4	116	16·0	7·3
0·0	980	—	—

It appears, thus, that a given stage in the decomposition is reached from three to seven times sooner with hydrochloric than with sulphuric acid.

It is impossible to calculate the concentration of the hydrogen ions in the solutions containing sulphuric acid, because the value of the equilibrium constant of the reaction $H^+ + SO_4'' \rightleftarrows HSO_4'$ is unknown. A rough estimate may be based on O. Tower's determinations of the concentrations of the hydrogen ions in solutions of sodium hydrogen sulphate (Zeits. phys. Chem., 18, 5, **18**, 45), and on the conductivity of sulphuric acid solutions.

The initial solutions in Experiments V. and VI. may be regarded as containing 3·92 $NaHSO_4$: 1·02 H_2SO_4. At the concentrations used, these two substances yield approximately equal quantities of hydrogen ions, and therefore the dissociation of either of them is not affected much by the presence of the other.

The concentrations of the hydrogen ions in the two solutions used in Experiments V. and VI., estimated in this way, are 0·027 and 0·05 grm. mol. per litre, that is 2·2 and 2·4 times less than in the corresponding experiments with hydrochloric acid. Since the velocity of change is proportional to the square of the concentration of the hydrogen ions, it should be 4·8 and 5·8 times greater with hydrochloric than with sulphuric acid. The difference between the rate of reaction observed with sulphuric and hydrochloric acids appears, therefore, to be satisfactorily accounted for by the smaller dissociation of the sulphuric acid.

The results obtained are valuable as affording a clue to the effect of the initial concentration of the solution on the yield of cyanogen bromide which can be obtained in a given time. The following table (calculated by means of Equation B^1) applies to the reaction, $HBrO_3 + 2HBr + 3HCN = 3CNBr + 3H_2O$ which is the only one which is of importance in practice.

Initial concentration of bromic acid (grm. mols. per litre.)	Percentage of the possible cyanogen bromide formed.		
	90.	95.	99.
0·05	8½ hours	67½ hours	1 year
0·1	68 mins.	8½ ,,	6½ weeks
0·2	8 ,,	63 mins.	132 hours
0·5	0·5 ,,	4 ,,	8½ hours

Since the acid used in practice is sulphuric acid, the times required will be still greater than those tabulated. Of course the time required for the last stages of the change could be shortened by using an excess of acid, but since the cyanogen bromide solution is to be mixed subsequently with a solution of an alkali cyanide, it is desirable to have it as nearly neutral as possible.

Mixing the charge.—In mixing a charge, the temperature should not be allowed to rise above about 35° C., since cyanogen bromide boils at 61° C. Good agitation should also be provided, in order to prevent the solution from becoming locally alkaline. Although hydrocyanic acid and cyanogen bromide have no action on each other, potassium or sodium cyanide reacts quickly with cyanogen bromide, thus, $KCN + CNBr = KBr + C_2N_2$; the sodium carbonate which is often present in commercial cyanide also decomposes cyanogen bromide thus, $CNBr + 2Na_2CO_3 + H_2O = 2NaHCO_3 + NaCNO + NaBr$. The further action of sodium bicarbonate is so slow that it may be neglected.

It may be remarked that even water decomposes cyanogen bromide; although the reaction is extremely slow at the ordinary temperature, it is very easily observed at 100°. Probably this accounts for the instability of imperfectly dried cyanogen bromide; the trace of hydrobromic acid formed by the action of moisture would, in presence of atmospheric oxygen, yield the bromine required to bring about rapid polymerisation.

The reactions of cyanogen bromide with alkali hydroxides and carbonates, and water, appear to be fundamentally the same, namely, $CNBr + 2OH' = Br' + CNO' + H_2O$. The different velocities of the reactions are due to the different concentrations of the hydroxyl ions in the reagents.

Analysis of solutions.—The working of the process may be controlled by analyses of the final solution. I have found the following methods to be convenient and accurate.

To an aliquot portion of the solution considerable excess of potassium iodide and hydrochloric acid are added, and the iodine liberated titrated with sodium thiosulphate. The quantity of iodine found should be the same as that which would have been produced by the bromic acid originally used. Any difference indicates a loss either of bromic acid or cyanogen bromide.

A second sample is treated in the same way after destroying the cyanogen bromide by adding sodium hydroxide. The difference between these results gives the cyanogen bromide present. The second result gives the quantity of bromic acid left unchanged. The quantity of cyanide left unchanged is determined in the way described previously. If the quantities left unchanged are excessive, it indicates that the time allowed for the reaction was insufficient, or that too little acid was used. The quantity of free acid in the final solution is easily determined by titration with a standardised solution of sodium bicarbonate, using methyl orange as indicator.

A few preparations of cyanogen bromide were carried out in order to confirm the results obtained by the study of the reaction. The "bromine salt" and cyanide used had the following compositions:—

Bromine salt.		Cyanide.	
$NaBrO_3$	14·61	KCN	30·33
$KBrO_3$	23·91	NaCN	51·17
NaBr	49·39	Na_2CO_3	13·70
Na_2CO_3	5·22	NaCNO	3·61
NaOH	0·45	Na_2O	0·54
Water	5·24	Na_2S	0·01
Fe_2O_3	0·78	NaCl	0·82
	99·60		100·18

5·27 grms. of the bromine salt and 2·47 grms. of cyanide were used in each experiment. The calculated quantity of 64 per cent. sulphuric acid (4·35 c.c.) was placed in a 200 c.c. burette with a tap funnel ground to fit its upper end, and provided with a small washing apparatus to catch cyanogen bromide vapour. The solid bromine salt was then placed in the tube, out of contact with the acid, the ground stopper carrying the funnel inserted, and the salt and acid mixed together, shaking and cooling the tube as well as possible. The cyanide was then added slowly in the form of a concentrated solution. The whole mass soon solidified to a thick paste of crystals of cyanogen bromide. After standing for a measured time, the product was diluted to 200 c.c. and measured quantities drawn off for analysis. The results of two such experiments were:—

	I.	II.
Initial concentration of bromic acid	0·7	0·7
Time of reaction	7 mins.	17½ hours
Per cent. of theory—		
Loss of cyanogen bromide	4·2	5·4
Yield of cyanogen bromide	81·3	85·7
Per cent. of theoquantity used—		
Unchanged bromate	14·5	8·9
Unchanged cyanide	11·5	6·1
Free acid	2·9	0·6
Free acid calculated	6·5	3·8

In the first experiment, the time was too short, and in both of them the concentration was too large, the mixture became so thick owing to the separation of cyanogen bromide that proper mixing was impossible. The main fault, however, was a deficiency of sulphuric acid; 57 per cent. of the acid is required to neutralise the cyanide and the carbonate in the bromine salt; of the remainder, 14·5 per cent. should be left unchanged in Experiment I., that is, 6·5 per cent. of the total quantity used.

A larger quantity of the acid was, therefore, used in the next experiments, and, in order to avoid the difficulty of mixing, the bromine salt and cyanide were mixed and added to the sulphuric acid in the form of a concentrated solution. Although the solution was only about one-half the former strength it still became pasty owing to the crystallisation of cyanogen bromide. The following results were obtained:—

	III.	IV.
Initial concentration of bromic acid	0·407	0·372
Time of reaction	3 hrs. 23 mins.	17½ hrs.
Per cent. of theoretical quantity—		
Loss of cyanogen bromide	2·6	1·9
Yield of cyanogen bromide	88·9	94·2
Per cent. of the quantity used—		
Unchanged bromate	8·5	3·9
Unchanged cyanide	6·4	1·7
Free acid	3·5	3·7
Free acid calculated	3·9	1·8

The results of these experiments show that the more closely the experimental conditions approach those which the theoretical study of the reactions has shown to be necessary, the more nearly do the yields obtained approach the theoretical value.

I am indebted to the courtesy of the directors of the Cassel Cyanide Company, Ltd., for permission to publish these results.

THE RELATION OF SOLUTION PRESSURE TO SURFACE CONDITION IN METALS.

CHARLES E. FAWSITT, D.SC., PH.D.

THE manner in which a metal is dissolved by an acid depends on the concentration of the acid and on the presence of impurities in it. It also depends on the temperature, the presence of impurities in the metal, and on the state of the metal surface. Many observers have noticed that the condition of the surface has a very great effect on the rate of solution. From a recent investigation (Trans. Amer. Chem. Soc., 1906, 9, 199; see page 1149) by

Burgess and Engle into the rate of solution of iron in acids, the following figures are taken :—

Loss in grms. per square inch of iron in normal sulphuric acid on a 17-hour run.

Compact, soft sheet iron	0·0279
Coarsely crystaline electrolytic iron.....	0·4805
The same, but denser deposit	0·3291
The same, heated red hot, and slowly cooled	0·225

The variation in these numbers may be taken as being solely due to difference in the surface condition.

The exact investigation of the surface condition by experiments of this kind is somewhat difficult, as the original surface is soon dissolved away and a new one exposed. There exists a more accurate method of treating the surface, which is, however, a measure of the static condition with regard to solution, and not the kinetic condition. This method lies in the determination of the electrolytic potential of a metal with respect to a solution of any one of its own salts in water. The potential varies with the concentration of the solution employed, but by using always a particular concentration—say normal—different specimens of metal may readily be compared.

The metals employed were in the form of thin rods. These were mostly about 4 ins. long and one-eighth of an inch in diameter. When being tested, the surface of the metals was coated with wax, except for a very small part specially selected for examination. The E.M.F. determinations were made by the compensation method, the calomel normal electrode being taken as standard for a single potential difference = +0·560 volt. It was often noticed that the potential of a rod of metal changed considerably when left in the solution. Iron is very bad in this respect, whether placed in a ferrous or ferric solution ; in fact, it is impossible to obtain any constant readings at all if the rods are kept still. By rotating the rods at about six revolutions per second, I obtained constant results, an increased rate of rotation had in most cases no effect.

The metals experimented with were silver, gold, and iron. The silver and gold used were pure ; the iron was used in several grades of purity. The presence of impurities in iron did not, however, have any considerable effect on the potential, as the following figures show. The surface in these cases was rubbed clean with coarse emery.

Single potentials in ferrous sulphate ($\frac{1}{2}$*-molecular*).

Iron (purest obtainable)	−0·082 volt.
0·18 per cent. carbon steel (slowly cooled) ..	−0·078 ,,
0·23 per cent. ,, ,,	−0·078 ,,
0·4 per cent. ,, ,,	−0·077 ,,
0·9 per cent. ,, ,,	−0·076 ,,

The potential of those steels is the potential of the ferrite they contain ; any cementite present has very little effect. It has been shown by Beilby (this J., 1904, 788) that metals exist in two phases, hard and soft. I have found that when (the surface of) a metal is in the crystalline or soft condition, its solution pressure is not so great as when in the amorphous or hard condition.

Silver in silver nitrate (*molecular*).

Brightly polished silver	+1·055 volt.
The same annealed by heating red hot	+1·066 ,,
The annealed silver after being hammered till hard	+1·057 ,,

The potential in the case of the silver hardened by hammering differs by about 0·01 volt from the annealed variety. The effect of polishing is to form a surface skin of hardened metal which is extremely thin, but the potential as found above is very nearly the same as for the hammered silver.

I give next similar measurements for gold :—

Gold in gold chloride (1-100-*molecular*).

Polished gold	+1.447 volt.
The same annealed	+1.454 ,,
Hammered gold	+1.422 ,,

Here again the hardened variety has a greater solution pressure than the annealed, but apparently the polished layer is not thick enough to give the same potential as the hammered specimen.

I wish next to show that a rough surface of a metal has a greater solution pressure than a smooth surface, the metal surfaces being otherwise in a similar condition.

Thus, a specimen of annealed silver with a smooth surface was found to have a potential of +1·066 volt. The rod was then etched with nitric acid until the surface became quite rough. The rod was then found to have a potential of +1·051 volt.

I give next some measurements on iron and steel in solutions of ferrous sulphate ($\frac{1}{2}$-molecular) and ferric chloride ($\frac{1}{2}$-molecular).

	Ferrous sulphate.	Ferric chloride.
Pure compact iron—		
Polished	—	+0·129
Rubbed with coarse emery	−0·082	+0·128
Electrolytic iron —		
Fresh from depositing bath	−0·147	+0·040
Heated gently in hydrogen	−0·071	+0·121
Heated red hot in hydrogen	−0·037	+0·138
Steel containing 0·4 per cent. carbon—		
Polished	−0·074	+0·146
Rubbed with coarse emery	−0·077	+0·144
Etched with nitric acid ..	−0·087	+0·132
Pumice blasted	—	+0·118
Cast iron shot blasted	−0·104	+0·097

With iron or steel, a roughening of the surface, whether produced by etching or blasting, produces an increase in the solution pressure. One may conclude that the greater solution pressure is due to the larger number of points exposed to the liquid. Theoretical considerations indeed would show that a point of metal should have a greater tendency to dissolve than a plane surface.

It will be noticed that the numbers obtained for electrolytic iron are similar to the solution numbers as found by Burgess and Engle. It may be assumed that an electrolytic deposit is crystalline, but that it is also somewhat loosely attached to the metal underneath, and will present many points or surfaces of great convexity to the solution. As a crystalline modification its solution pressure should be small, but as a surface exposing many points its solution pressure should be large. The freshly precipitated form has a large solution pressure which is, however, greatly reduced by heating. This may possibly be due to the iron shrinking to a more compact form, as well as to a rounding off of the points of metal at a temperature far below the melting point. I am much indebted to the Brymbo Steel Co., Ltd., for specimens of steel which they placed at my disposal, and to Mr. H. L. Heathcote, of Coventry, for several suggestions in regard to the potential of iron and steel.

I.—PLANT, APPARATUS, & MACHINERY.

(*Continued from page* 1081.)

Dialysis under sterile conditions; New method for ——. H. T. Brown, F. Escombe, A. McMullen, and J. H. Millar. Trans. Guinness Research Lab., 1906, 1., 300—305.

THE authors have designed a diffusion apparatus which possesses the advantage of enabling a relatively small volume of liquid to be dialysed on a large area of dialysing membrane, the liquid on either side of the membrane being kept in motion, and means being provided for ensuring the sterility of the liquid in the cell. The dialysing cell is shown in the figure at A. It consists of two brass frames clamped together with the membrane of parchment paper between them. The faces of the two frames are cast in a zig-zag

or corrugated form so as to afford rigidity, and a maximum length in a minimum of space. The faces are channelled out to the depth of $\frac{1}{8}$ in., so that when clamped together they form a diffusion cell $\frac{1}{4}$ in. deep, divided into two equal compartments by the paper diaphragm. The brass tubes, *a*, *a'*, are in connection with the two end of the upper chamber and the tubes, *a''*, *a'''*, with those of the lower chamber. The solution flows through the upper compartment from left to right, and the water through the lower one from right to left. The solution, 1000 c.c., is placed in the tapped funnel, C, about 300 c.c. being allowed to flow down the tube, C', into the vessel D, in the bottom of which is placed a seal of mercury to prevent back suction up C'. The circulation of the liquid takes place by gravity from C, through D, D', *a*, A, *a'*, into E. From E, it is sucked by a pump through the vertical tube, *c*, passing through a coil in the copper sterilising vessel, F, and then by way of *f*, back into C. The liquid is re-sterilised every day by boiling the water in F. The circulation of water takes place from the 8-litre vessel, G, fitted with a 5-litre funnel in its neck, constituting a constant-level reservoir. The water passes out through *g* into H, in which its flow is measured. From H, it passes through the cell, A, and comes out at *a''*. The diffusate is collected in the vessel, K, which is open to the air, and the flow is regulated at the rate of 5 litres in 6 hours. As the diffusate accummulates, it is sucked into the vacuum pan, L, in which it is concentrated, and the product is withdrawn into the flask, M, by suction applied to the vessel, N.—J. F. B.

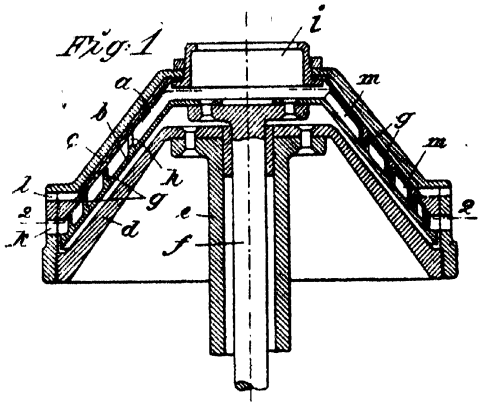
ENGLISH PATENTS.

Measuring the flow of gases and other fluids and liquids; Apparatus for ——. E. W. Monkhouse, London, and F. W. Burstall, Birmingham. Eng. Pat. 837, Jan. 12, 1906.

THE claim is for a method of applying the principle of measuring the flow of fluids by observing the difference of pressure between two points in a pipe. The difference of pressure between the two points depends upon the length and cross-sectional area of the pipe, and the quantity of fluid flowing through it in a given time. The invention consists in causing the fluid which is to be measured to pass equally through a number of calibrated parallel pipes, so that, by measuring the flow in any one or more, the flow through the whole number can be calculated. The pipes are arranged either in an annular ring or in groups between two plates, which are attached at each end to a casing which serves to connect the apparatus to the main. If the pipes are of equal diameter and are arranged in a ring, the equal distribution of the fluid is attained by placing a distributing cone with its apex pointing in the opposite direction to that in which the fluid is moving. If, however, the arrangement in groups or concentric rings is adopted, the cone is omitted, and the pipes are made of different diameters, those in the direct path of the fluid being smaller than the outer ones in order that an equal volume may flow through each of the pipes.—W. H. C.

Centrifugal machines for drying purposes. R. Haddan, London. From Aktiebolaget Separator, Stockholm. Eng. Pat. 16,003, July 14, 1906.

Fig. 1.



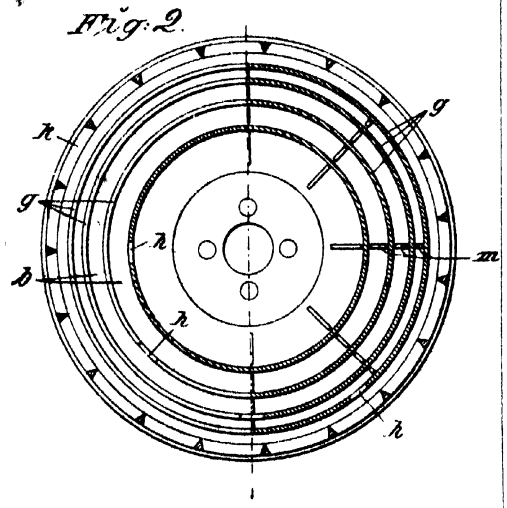


Fig. 2.

In the figures, two constructional forms of the invention are shown; one on the left and the other on the right. The material to be separated is fed through the opening, *i*, and flows between the upper perforated disc, *a*, and the lower solid disc, *b*. The disc, *a*, is carried by the cover, *c*, which is attached to the bottom piece, *d*, carried and rotated by the hollow shaft, *e*. The disc, *b*, which is provided with rings, *g*, shown attached to the disc, *b*, on the left, and to the disc, *a* on the right of the figure, is carried and rotated by the solid shaft, *f*. The material is pressed against the disc, *a*, and the upper ring, *g*, by centrifugal force, and the liquid passes through the perforations to the liquid outlet, *l*. The two discs are rotated at different speeds, and the ring, *g*, which has an opening, *h*, moves, in the case shown on the left of the figure, relatively to the mass pressed against the disc, *a*, so that the solid matter passes continuously through the opening, *h*. It then presses against the next ring, *g*, and passes from ring to ring until it escapes from the solids outlet, *k*. On the right of the figure the rings, *g*, are shown attached to the disc, *a*, and scrapers, *m* (see Fig. 2), are provided, attached to the disc, *b*, to cause the solids to pass through the openings, *h*.—W. H. C.

Centrifugal separators for liquids. C. G. P. de Laval and E. E. F. Fagerström, Stockholm. Eng. Pat, 18,707, Aug. 21, 1906.

The proportion between the quantities of the liquids separated is controlled by the insertion of a ring or flange inside the neck portion of the drum-cover, or of the top plate, or both. The flanges or rings are provided with one or more apertures, the size of which can be adjusted by other rings which are relatively movable and are provided with corresponding openings.—W. H. C.

United States Patents.

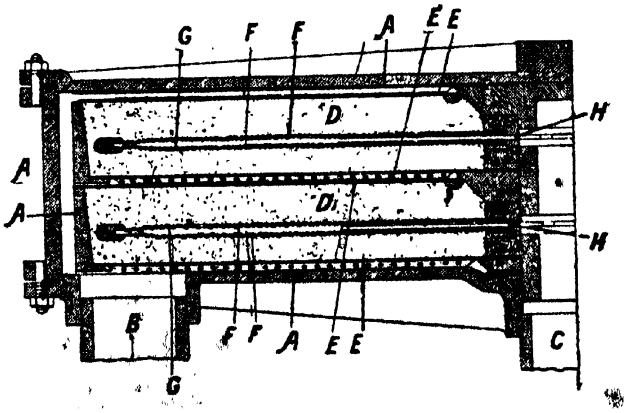
Separator; Centrifugal ——. N. S. Bök, Stockholm. U.S. Pat. 834,254, Oct. 30, 1906.

See Eng. Pat. 9115 of 1905; this J., 1905, 1004.—T.F.B.

Dehydrating apparatus. E. W. Cooke, New York, Assignor to The Cokel Co. U.S. Pat. 834,265, Oct. 30, 1906.

See Eng. Pat. 14,854 of 1905; this J., 1905, 1319.—T.F.B.

Dryer. J. M. White, Mapletonborough, Pa., Assignor to F. O'Connor, Mapleton Depot, Pa., and R. Tyne Smith, jun., Baltimore, Ind. U.S. Pat. 834,696, Oct. 30, 1906.



A furnace is built at the bottom of a stack or drying-tower, the lower half of which is fitted with alternately disposed, inclined plates, having curved upper edges and upturned lower rims. Spaces are left at the sides of the plates to allow the upward passage of the gases, and the material to be dried travels downwards from plate to plate. In the upper part of the tower, above the plates, are oppositely inclined series of sloping screens, the uppermost series of which is surmounted by a conical screen. —W. H. C.

Air-drying apparatus. C. O. Williams, Assignor to Federal Gas Co., St. Louis, Mo U.S. Pat. 834,698, Oct. 30, 1906.

The air is passed through chambers provided with slightly inclined corrugated shelves on which the drying medium is placed. The shelves spring alternately from opposite sides of the chamber, leaving a space on alternate sides of each shelf, so that there is a continuous passage through the chamber for the air. Several chambers may be combined into a series, and provided with a suitable arrangement of pipe connections and valves so that any chamber in the series may be cut out of action. Each chamber has a drain pipe at the bottom to convey away any liquid to a bank placed below.—W. H. C.

Filter. J. T. H. Paul, Assignor to E. Goldman and Co., Chicago, Ill. U.S. Pat. 834,637, Oct. 30, 1906.

The claim is for a filter, a half sectional view of which is

shown in the figure, and which consists of a casing, A, having an inlet pipe, B, and a central outlet, C. Filter elements, D, are arranged in the casing, and the liquid to be filtered enters at B, circulates in the direction indicated by the arrows, passes through the perforated plates, E,E, through the filtering material, D, and escapes through the perforated sides, F,F, of the collecting chambers, G, from which it flows through the openings, H, into the central discharge pipe, C.—W. H. C.

French Patents.

Concentrating liquids; Apparatus for ——. J. F. P. Kestner. Fr. Pat. 361,739, Sept. 2, 1905.

The claim is for increasing the output of ordinary single or multiple effect evaporators by the addition to each effect of the "Kestner" evaporator tubes described in Fr. Pat. 315,973 of 1901 (this J., 1903, 788).—W. H. C.

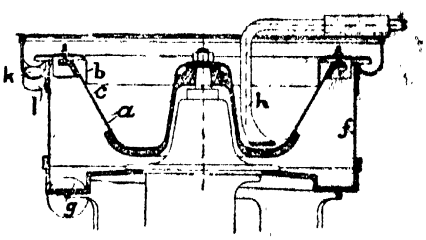
Drying chamber. C. H. Vandamme. Fr. Pat. 357,536, June 25, 1906.

The claim is for the division of the drying chamber into parallel compartments and for the sub-division of the latter into triangular spaces. This is effected by causing the continuous travelling band which carries the material to pass over rollers arranged in triangles in the parallel chambers. The latter are provided with fans and heating pipes, which are close to but do not touch the band.—W. H. C.

Drying apparatus; Continuous - . Aktiebolaget Separator. Fr. Pat. 368,118, July 17, 1906.

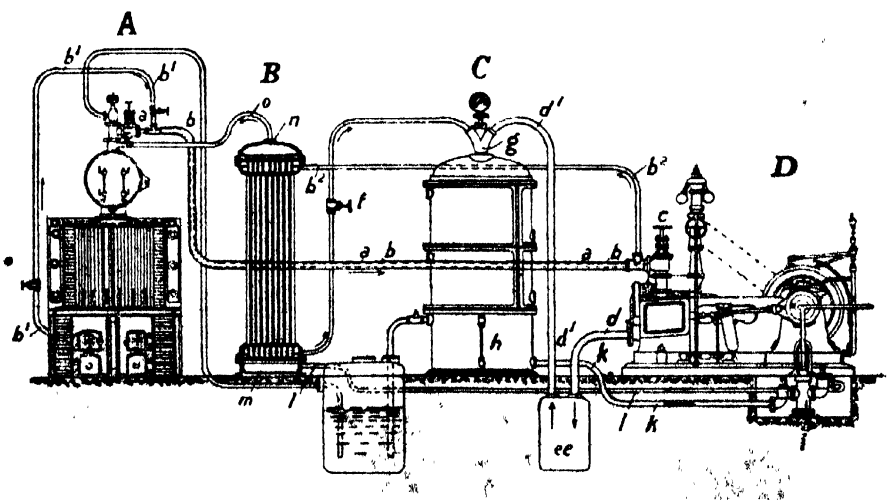
See Eng. Pat. 16,000 of 1906; this J., 1906, 1081.—T.F.B.

Ammonia vapour of high tension for use as a motive power; Process for the continuous production of - -. Neue Betriebskraft Ges. Fr. Pat. 367,679, June 29, 1906.



A 25 per cent. solution of ammonia is heated under a pressure of eight atmospheres in the boiler, A, to about 100° C., so that a portion only of the gas is evolved. This gas leaves the boiler by the pipe, *a*, which is surrounded by the concentric pipe, *b*, and the hot weak liquor from the boiler is drawn off through the pipe, b^1, and the annular space between the pipes, *a* and *b*. The two travel side by side as far as the inlet valve, *c*, of the engine, D, so that the temperature and consequently the pressure of the gas is maintained. The exhaust ammonia gas passes from the cylinder by the pipe, *d*, to the oil-catcher, *e*, and thence to the interior of the surface condenser, C, by the pipe, d^1. The condenser, C, contains a large number of cooling pipes through which cold water circulates, and cool weak liquor from the heat interchanger, B, is injected into C in the form of fog by the pulveriser, *g*. The gas and fog condense together, producing a vacuum in the condenser, C, and collect at the bottom in the chamber, A. From A, the cold strong liquor is drawn off through the pipe, *k*, by the pump, *i*, and delivered by the pipe, *l*, into the bottom chamber, *m*, of the heat interchanger, B; it passes up the tubes and takes up heat from the hot weak liquor which enters at the top of the space surrounding the tubes by the pipe, b^2. When the strong liquor reaches the upper chamber, *n*, it is already nearly at the same temperature as the liquid in the boiler, A, to which it is returned by the pipe, *o*, whilst the weak liquor, having become quite cold, leaves the bottom of the heat interchanger, B, by the pipe, *f*, to re-absorb gas in the surface condenser, C. It is stated that, as only a small quantity of heat is required to boil off a portion of the ammonia in the boiler, A, compared with the amount required to completely deprive the liquor of its gas, the consumption of fuel is very low.—W. H. C.

Evaporation and desiccation of materials at a low temperature; Apparatus for the progressive ——. C. E. Chamberland. Fr. Pat. 367,783, July 5, 1906.



The apparatus consists of a drying chamber, preferably with a glass top, in which the material to be dried is placed in layers and through which air or some other suitable gaseous medium, maintained at a low degree of saturation, is circulated by a pump or fan. The same volume of gas is used continuously, being drawn from the drying chamber through a water-cooled condenser, where the liquid it has taken up is condensed and drawn off by the pump or fan, and delivered to a heater from which it returns to the drying chamber. The pump may be driven by a water motor, and the waste water used to cool the condenser.—W. H. C.

German Patent.

Centrifugal apparatus for the separation of liquids from suspended solid matter. C. G. Haubold, jun. Ger. Pat. 171,291, Oct. 25, 1903.

The apparatus is shown in the accompanying figure. A movable ring, *b*, is suspended in the upper part of the rotating bowl, *a*, so as to leave an annular slit, *c*. The

liquid is introduced through the pipe, *h*; as the bowl is rotated, the heavier solid particles passing through the slit, *c*, over the edge, *e*, of the bowl into the containing vessel, *f*, from which they are removed at *g*. The liquid, freed from solids, overflows into the channel, *k*, and is removed through the pipe, *l*.—A. S.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 1085.)

Coal and other combustibles; Calorific value of ——. G. Arth. Bull. Soc. d'Encouragement, 1906, Rev. Metall., 407—408.

The author points out that in the usual determination of the calorific value of a fuel, it is assumed that the products of combustion are cooled to the ordinary temperature, and that the result is therefore higher than can ever be realised in technical practice, where the resulting gases always leave the flues at a temperature above 100° C. The association of German and Austrian engineers have agreed that calorific values should be calculated on the assumption that the whole of the products are cooled only to 100° C., and that the water formed remains as steam. The author advises the adoption of this plan in France, under the name of "lower calorific value," distinguishing the calorific value as at present stated as "higher calorific value." With bituminous coals or other fuel containing 4—6 per cent. of hydrogen, the difference between these values, due to hydrogen, will be from 3—4·5 per cent. of the total.—J. T. D.

Acetylene; Causes of explosions with ——. N. Caro. Verein z. Beförd des Gewerbefleisses Verh., 1906. 205—236, 245—292. Science Abstracts, 1906, 9A, 523.

To explain the causes of the mysterious explosions which have sometimes occurred with acetylene, the author has made an exhaustive investigation of (1) the explosive properties; (2) the effect of the decomposition process upon explosive properties; (3) the effect of heat and steam; (4) effect of impurities. With regard to (1) the author's experiments on the explosion of acetylene under various pressures in a steel bomb gave resulting pressures considerably higher than Berthelot's (*viz.*, at 12 atmos. initial, the end pressures are: Berthelot, 93; Caro, 128 atmos.). The closer approximation of the acetylene molecules increases the propagation of the decomposition, and gives rise to the explosive effect; even when dissolved in acetone, acetylene is explosive, and gives the same final pressures as pure acetylene, and even higher end-pressures with higher initial pressures, owing to decomposition of the acetone. Acetylene mixed with inert gases under pressure (for the purpose of separating the molecules) has a somewhat diminished explosibility. At −80° C. neither compressed nor liquid acetylene can be exploded, hence the diluting substance which reduces explosibility is considered to act as an internal cooling agent. As regards dilution with air, 25 per cent. of air to acetylene, or 3 per cent. of acetylene to air, is enough to produce an explosive mixture. (2) The heat set free during decomposition of the carbide neither directly nor indirectly increases the explosibility of pure acetylene at atmospheric pressure. (3) Heating produces an increase in the explosibility at higher pressures, so that sometimes at little over 1½ atmos. only, acetylene has been exploded, in the case of dry gas. With steam present, the explosibility is increased, without the usual softening influence of the hydrogen being observable. As regards acetylene and air mixtures, heating increases the explosibility; the presence of water vapour, which, being endothermic, should reduce the explosibility, was found to actually do so when the explosion takes place at constant pressure (when the gases can at once expand). In closed vessels, however, with excess of acetylene the explosibility is apparently increased. Finely-divided metals or sulphides cause ignition.

Power obtainable from metallurgical waste gases. C. Richter. X., page 1151.

Carbon monoxide; Action of —— on steam at red heat, and action of hydrogen on carbon dioxide. A. Gautier. VII., page 1145.

English Patents.

Coke ovens. A. O. Jones, New Brancepeth, Durham. Eng. Pat. 11,660, May 18, 1906.

A vertical coke oven is heated by a series of independent, horizontal, combustion flues which extend along one side of the oven, from the front to the back, across the back, and along the other side to the front, where they open into a common flue leading to the chimney. The upper portion of the oven is provided with a surrounding flue, through which air is circulated, to cool the upper portion, and prevent decomposition of the evolved gases. The oven is charged through an opening at the top, of the full size of the upper part of the oven, by means of a travelling hopper, running on rails mounted on the front and rear walls of the battery of ovens. The charging opening is closed by a hinged cover. Discharging is effected by means of a sliding door at the foot of the oven.—H. B.

Gas producers. Cleland's Graving Dock and Slipway Co., Ltd., Willington Quay on Tyne, and A. B. Roxburgh, Whitley Bay, Northumberland. Eng. Pat. 22,046, Oct. 30, 1905.

The producer is preferably of rectangular cross-section, and has a grate consisting of vertical bars forming a vertical surface in line with the brick lining above it to allow free descent of the fuel; or the grate may be outwardly inclined towards the bottom. By this arrangement the air is admitted above the ash and clinker. The grate is carried by a casing in the producer wall closed by a door, and forming a chamber for admission of air and steam. The lining opposite the grate slopes inwardly, and the bottom of the producer terminates in a water seal with sloping front for removal of ash and clinker. The gas outlet is near the top of the side opposite the grate, and is provided with a grating of slats inclined upwards. The hot gas passes through a brick-lined chamber containing a boiler, from which steam is led to the admission chamber. —A. T. L.

Gases under pressure for power purposes; Combustion apparatus for production of —— G. J. Weber, Kansas City, U.S.A. Eng. Pat. 22,229, Oct. 31, 1905.

A combustion-chamber with non-conducting lining is connected by a pipe to the valve-chest of an engine of the condensing and expansion type. The chamber is fitted with a grate, doors for charging with coal and withdrawing ashes, and a safety valve. The fuel is ignited, the doors closed, and air admitted under pressure from a receiver by an inlet pipe below the grate. The receiver is charged by a hand-pump at starting. Products of combustion are generated under pressure and used in the engine, which drives an air-compressor from an eccentric on the crank-shaft, to supply air for combustion. The pressure in the combustion chamber actuates a piston controlled by a spring, so that when the pressure exceeds the desired limit, the piston is forced back and operates the air-supply valve through a system of levers. A second combustion chamber may be used for burning oil, such as gasoline. The oil and air enter by concentric pipes, and the supply of each is controlled by the pressure in the combustion chamber, as described above. The top of the oil tank is connected to the air reservoir to obtain the pressure necessary to force oil into the combustion-chamber.—A. T. L.

Gas producer apparatus; Construction and working of ——. T. W. S. Hutchins, Manchester, and J. B. Wilkie, Liverpool. Eng. Pat. 24,443, Nov. 27, 1905.

A gas producer plant, in which the gas is drawn from the scrubbers and producer by an exhausting fan, is combined with a gas pressure governor connected to the outlet of the fan, and arranged so that an increase of pressure causes a throttling of the gas supply from the fan. The producer thus delivers a variable supply of gas at constant pressure according to the consumption, without the use

of a gas-holder. The governor described has a bell working in a water or other seal, and actuating a lever which brings a plate opposite the outlet of the fan.—A.T.L.

Illuminating and heating gas [from oils]; Process for the production of permanent ——. W. J. Dibdin and H. C. Woltereck, London. Eng. Pat. 26,666, Dec. 21, 1905.

A MIXTURE of hydrocarbons (paraffin) and superheated steam, in finest division, is passed at high temperature (bright orange) over a porous, spongy contact material consisting of ferrous-ferric oxide, containing, preferably, free protoxide. The contact material may be obtained, preferably, by passing steam and an excess of hydrocarbons for several days through an iron or steel retort, filled with thin iron tubes and kept at a bright red heat, until no metallic iron is left in the thin tubes. For the production, with such material, of gas of 16-candle power, the ratio of hydrocarbons to steam is kept at about 1 to 10. It is stated that 1 ton of crude petroleum will produce about 100,000 cb. ft. of 16-candle gas, of composition resembling that of ordinary illuminating gas.—H. B.

Incandescent electric lamp filaments; Manufacture of —— from thorium. British Thomson-Houston Co., Ltd., London. From General Electric Co., of Schenectady, N.Y. Eng. Pat. 14,972A, July 20, 1905.

THORIUM powder (obtained, for example, according to Eng. Pat. 14,972 of 1905; this J., 1906, 866) is mixed with from 20 to 100 per cent. of clean magnesium filings; the mixture is compressed into a lump, and heated in a vacuum furnace (such as described in Eng. Pat. 20,809 of 1904; this J., 1905, 976) till all the magnesium has been driven off; and the porous, sintered mass of thorium thus obtained, after cleansing with nitric acid, can be compressed into a dense metallic state, and rolled and drawn into wire.—H. B.

UNITED STATES PATENTS.

Producer-gas; Apparatus for manufacturing ——. W. H. Adams and F. Powell, Portland, Oreg., Assignors to the Ladd Metals Co., Oregon. U.S. Pat. 834,238, Oct. 30, 1906.

THE fuel chamber of the producer described is elongated in a horizontal direction, and fuel is fed in at the centre from above. The air inlets are all arranged at one end of the longer dimension, and the gas outlet is a forward horizontal extension, at the other end. The inlets and outlet are both located at the same level, and below the plane of the bed of fuel in the chamber. In this way a horizontal zone of incandescence is established along the chamber, the anterior portion of which acts as a generator, and the posterior portion as a regenerator, acting on the products of combustion from the anterior portion. The grate of the producer is surrounded by a "skirt" that dips into the water of the ash-pan, and the space enclosed by the skirt is divided by a vertical diaphragm. This diaphragm shuts off air or steam, admitted by suitable inlets into the water-sealed space below the grate, from a portion of the grate.—W. C. H.

Illuminating gas; Apparatus for the manufacture of ——. W. H. Adams and F. Powell, Portland, Oreg., Assignors to The Ladd Metals Co., Oregon. U.S. Pat. 834,239, Oct. 30, 1906.

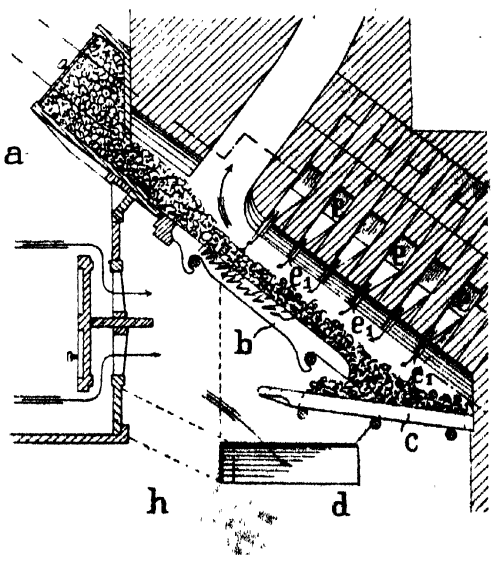
THE generator of this apparatus is elongated in a horizontal direction, and provided with a fuel supply hopper at the top, to supply fuel without admitting air to the generator. The air supply inlets are at one end of the longer horizontal dimension, and the outlet for products of combustion at the other end, both being below the level of the top of the bed of fuel, whereby a horizontal zone of combustion is maintained in the generator, which is provided with a water-seal ash-pan (see preceding abstract). The products of combustion pass into a chamber containing a retort, which is thereby heated. Above the top of the bed of fuel in the generator is an outlet for products of distillation of the fuel; these products are led into the heated retort, and there converted into fixed gases.—W. C. H.

Illuminating gas; Process of manufacturing ——. W. H. Adams and F. Powell, Portland, Oreg., Assignors to The Ladd Metals Co., Oregon. U.S. Pat. 834,241, Oct. 30, 1906.

THE process described consists in establishing a horizontal zone of combustion in a long horizontal body of fuel, and a zone of distillation above the zone of combustion; the products of these two zones are removed through separate channels, and the outflow of the distillation products is regulated in accordance with the colour of the two products when burned. (See U.S. Pat. 834,239 above.)—W. C. H.

Carburetter. C. O. Williams, Assignor to Federal Gas Co., St. Louis, Mo. U.S. Pat. 834,697, Oct. 30, 1906.

A VERTICAL casing is divided into compartments by horizontal plates, which have openings arranged on the opposite sides of alternate plates, so that the air or gas which enters through a pipe at the bottom of the casing is forced to take a tortuous path through the apparatus. Steam is delivered into the apparatus through a pipe which enters the casing some distance up, and passes centrally down through the plates into a heating drum disposed in a space below the lowest plate, and provided with a pipe for the escape of condensed water. Oil is fed into the apparatus through a pipe above the steam-inlet pipe, and drops on to the bend of the steam pipe, and thence into a series of oil funnels, surrounding the steam pipe where it passes through the plates. The oil is vaporised in these funnels, and the vapour is taken up by the ascending current of air or gas.—W. H. C.



FRENCH PATENTS.

Coal; New artificial ——, *composed of a mixture of beet pulp, fine coal, wood charcoal, or coke, and a binding medium.* J. P. Reneaux, Addition, dated June 19, 1906, to Fr. Pat. 366,141, April 28, 1906.

THE ingredients mentioned in the original patent may be supplemented by powdered anthracite and fine coal, charcoal, anthracite or coke, ground beet leaves, the sludge or cakes of scum from the clarification and filtration of beet juice, beet vinasse or molasses residue, or all waste and by-products from the treatment of beet in sugar making.—C. S.

Smoke-consuming furnace. A. Sickert. Fr. Pat. 367,785, July 5, 1906.

THE fuel is charged at the top, *a*, of the inclined bars, *b*, and passes down to be finally completely burnt on the

horizontal bars, *c*. Air is drawn from the ash-pit, *h*, through openings, *d*, on each side into the flues, *e*, where it is heated and discharged downwards upon the fuel on the inclined bars, *b*, through the ports, e^1, so that it effects the complete combustion of the smoke.—W. H. C.

Gas-producer; Carburetting ——. G. Lézier. Fr. Pat. 361,752, Sept. 6, 1905.

THIS producer is arranged to yield a mixture of gas obtained from the distillation of wood, water-gas, and the permanent gases derived from a carburetting liquid, and a portion of the gases from the fire used to heat the distillation retort, after they have been reduced by passing through the incandescent material in the retort. The apparatus consists of a retort, heated by a suitable fire, in which wood, &c., can be distilled. Air, water, carburetting liquid, and products of combustion from the fire can be admitted, in regulated quantities, into the upper part of the retort, and the mixed gas produced is withdrawn from the bottom of the retort in such a way that the gaseous elements admitted to the upper portion become reduced by passing through the incandescent carbonaceous material in the lower portion.
—W. C. H.

Hydrogen; Manufacture of ——. Mme. Elworthy, née E. G. Cooper. First Addition, dated June 16, 1906, to Fr. Pat. 355,324, of June 17, 1905 (this J., 1905, 1164).

THE present addition relates to the separation of carbon dioxide from the mixture of gases derived from water gas, containing hydrogen, carbon monoxide, methane, and carbon dioxide, described in the main patent. The carbon dioxide is separated by simple compression of the cooled gaseous mixture, or by compression followed by expansion, when the carbon dioxide is liquefied or solidified, and can be removed. The gases escaping from the apparatus are utilised for cooling the incoming gases.
—E. S.

Incandescence gas mantles. T. P. Laycock. Fr. Pat. 367,488, June 27, 1906. Under Int. Conv., May 17, 1906.

THIS invention consists in coating or impregnating mantles for incandescence gas lighting with platinum bichloride, by immersing them in, or spraying them with an alcoholic solution of the salt.—W. C. H.

Candles or other illuminating bodies for nightlights, lamps, or other applications; Process for making —— by means of petroleum or other mineral oils. V. J. Kuesp. Fr. Pat. 367,448, June 26, 1906. III., page 1141.

Luminous bodies; Manufacture of electric — — by heating to incandescence metallic filaments in an atmosphere of a suitable gas by means of the electric current. Deutsche Gasglühlicht A.-G. (Auerges.). Fr. Pat. 367,467, June 26, 1906.

SEE Eng. Pat. 14,901 of 1906; this J., 1906, 1083.—T.F.B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 1085.)

Petroleum fields of Trinidad. C. Craig. Petroleum, 1906, 2, 86—88.

THE position of Trinidad at the mouth of the Orinoco has led to the gradual deposition of alternating fluvial and marine strata, favouring the formation of petroleum from accumulations of vegetable matter, such as can be seen in adjacent marshes and lagoons. Where the cover rock of these accumulations has permitted the escape of the gaseous decomposition products, the residue has the character of lignite or coal; but where such escape was impossible, the residue is petroliferous or bituminous, without any trace of vegetable matter. The tertiary strata contain three oil horizons, the Galeota oil sand being lowest and nearest the chalk. Next, at an interval of 3600—4000 ft., is the Rio-Blanco oil sand; and some 1400—1500 ft. above this is the La Brea oil sand, forming the source of the pitch lake, and only containing oil in the western side of the island. These oil horizons rise to or near the surface along three anticlinals—one extending from Galeota Point to Icacos Point; the second from Mayaro Bay to Point Ligoure, and the third from Mayaro Point to the mouth of the Vance River. There is also another anticlinal in the central mountain chain, with a few smaller ones elsewhere. Surface indications of oil are frequent in the cliffs, along watercourses, and in springs in the forests, in addition to numerous mud volcanoes, many of which are active, especially in the Cedros district. Shows of oil are plentiful all along the first anticlinal; and in the second between Mayaro and Point La Fortunée, as well as in the Guapo district, where the cliffs show five layers of petroliferous and bituminous sand 120 ft. thick. Further inland the same formation furnishes enormous deposits of soft and hard asphalt. The only known deposits of any extent in the La Brea oil sand are near La Brea and the pitch lake. All three horizons are accessible to boring along the anticlinals, and many of the shows are favourably situated for proving the deposits. The oil is low in sulphur, and the oil from the Galeota oil sand has the sp. gr. 0·880—0·910, and yields 12—20 per cent. of petroleum naphtha 30—50 per cent. of burning oil, 30—45 per cent. of lubricating oil, and only about 5 per cent. of residual resin. That from the Rio Blanco sand is richer in lubricating oil and residue. The total area of the oil-field is estimated at not less than 500 sq. miles.—C. S.

Petroleum; Bromine value of ——. Utz. Petroleum, 1906, 2, 43—45.

THE Vaubel method for determining the bromine value of oil of turpentine requires modification before it can be advantageously applied to petroleum, the best results being obtained with a solution containing 2·783 grms. of potassium bromate, instead of 13·92 grms. per litre. The following values were obtained in this way: Roumanian petroleum, 0·56—0·8; Russian "Meteor" oil, 0·72; "Nobel" oil, 0·8; Austrian oil, 0·88; Galician export oil, 1·44; Deutsch-Amerikanische Co.'s oil, 1·76; Pennsylvania oil, 2·0; "Arc light" oil, 2·56. American oil has thus the highest bromine-absorption value; Russian and Austrian the lowest, whilst Galician occupies an intermediate position. The results follow the same general trend as the iodine values, though the figures are lower; but there is no regular relation between the two values, the bromine absorption of the several fractions varying irregularly in the different oils. Nevertheless the method enables American oil to be easily distinguished from that of European origin, and the modified Vaubel method enables the determination to be made in less time than the iodine test. The bromate solution should be added by degrees, 1 c.c. at a time at the beginning, and 1/10th c.c. afterwards. The Graefe method may also be used as a preliminary test.—C. S.

Petroleum; Bromine value of ——. M. Weger. Petroleum, 1906, 2, 101—102.

THE author's determinations of bromine values of various samples of petroleum agree fairly well with those calculated from Graefe's iodine values, except in the case of Roumanian oils. Both sets of figures have, in his opinion, less importance than in the case of fatty oils, which are of more accurately known composition. He also thinks the bromine value gives no reliable indication of the origin of petroleum samples as claimed by Utz (see preceding abstract). The circumstance that water-white oil has a bromine value only about half that of standard white seems to indicate that the difference is due to decomposition of the oil during distillation—to which American oil is, from its composition, more liable than Russian oil.—C. S.

Petroleum distillates and residuum; Determination of the pitch content of —— by the sulphuric acid method. K. Charitschkow. Petroleum, 1906, 2, 99—101.

THE method furnishes results that are in no wise con-

cordant with the depth of colour of the oils. For example, in one case where the colour indicated a pitch ratio of 6·5:7 between two samples, the sulphuric acid test (diminution of volume on treatment with the acid) gave the proportion as 1:2; and in others a still greater discrepancy was observed. Potassium bichromate is also inefficient as a decolorising agent; and the Landsberg acetone method only dissolves out the heavier portions of the oil, masut, for instance, being soluble to the extent of 50 per cent., and "goudron" to 32·3 per cent., the residue having the appearance of solar oil, though of higher viscosity than the latter. The acetone method, however, appears suitable for the cold fractionation of petroleum.—C. S.

Petroleum refining; U.S. Census of ——. Oil, Paint, and Drug Rep., Oct. 29, 1906. [T.R.]

THE industry engaged in the refining of petroleum reported 98 establishments in 1905 having a product valued at $175,005,320, as compared with 67 establishments having a product of $123,929,384 in 1900. The capital of the industry in 1905 was $136,280,541, as compared with $95,327,892 in 1900. It should be understood in this connection that the item of capital in all census reports embraces tangible assets only and bears no relation to issues of stocks and bonds. The following table shows the materials used by kind, quantity, and cost, and the products, by kind, quantity, and value:—

UNITED STATES PATENT.

Emulsions [of bitumen, &c.] and process of producing them. K. Mann, Zurich, Switzerland. U.S. Pat. 834,830, Oct. 30, 1906.

SEE Fr. Pat. 354,648 of 1905; this J., 1905, 1103.—T.F.B.

FRENCH PATENTS.

Candles or other illuminating bodies for nightlights, lamps, or other applications; Process for making —— by means of petroleum or other mineral oils. V. J. Kuess, Fr. Pat. 367,448, June 26, 1906. Under Int. Conv. April 3, 1906.

TEN parts each of an animal and vegetable fat (*e.g.*, stearin and coprah oil) are melted together and saponified with 9 parts of commercial caustic potash dissolved in 18 of water. One hundred parts of petroleum are stirred in at a temperature of 30°—35° C., the whole setting to a solid mass. After several days, this mass is melted at 105°—115° C. and incorporated with 2—3 parts of water containing in solution alum, boric acid, or magnesium sulphate (according to the result desired) equivalent to 2—5 per cent. of the mass. The operation is conducted so that only a little over 5 per cent. of water is left in the product, the remainder being removed by evaporation. This product may be incorporated with its own weight of a mixture of equal parts of melted stearin and hard paraffin scale, and moulded into candles.—C. S.

Petroleum or other mineral oils; Process of solidifying ——, and transforming them into a solid hydrocarbon soap. V. J. Kuess, Fr. Pat. 367,449, June 26, 1906. Under Int. Conv., April 3, 1906. (See preceding abstract.)

PETROLEUM is mixed with 10 per cent. each of melted saponifiable animal and vegetable substances, the mixture being saponified with 9 parts of caustic potash dissolved in 24 parts of water, and left for 1—2 days, after which the mass is remelted and mixed with 2—5 per cent. of boric acid, borax, or other boron derivative (dissolved in a little water), and cast in moulds. The hardness of the product is in proportion to the amount of added boron derivative. To convert the product into soap, it is boiled

along with a lye (18° B.) of caustic soda and potash in equal proportions, 5 per cent. of coprah oil being added, for 24 hours at a temperature of 110°—115° C. The soap contains about 33 per cent. of water.—C. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 1089.)

Sodium hyposulphite [hydrosulphite]; Use of —— as a reducing agent. E. Grandmougin. Ber., 1906, **39**, 3561—3564.

FURTHER examples are given (see this J., 1906, 805) of the use of sodium hyposulphite as a reducing agent. Thus β-naphthoquinone is obtained from Orange II. by boiling a solution of 100 grms. of the dyestuff in 750 c.c. of water with 100 grms. of sodium hyposulphite, concentrated (B.A.S.F.), which have been gradually added. The aminonaphthol is filtered off, and oxidised by dissolving in 200 c.c. of dilute sulphuric acid (1:2), and, after cooling, adding a solution of 30 grms. of sodium bichromate. The naphthoquinone separates and is filtered off. In a similar manner 1:4-naphthylenediamine is obtained from benzeneazo-α-naphthylamine. The reagent may also be used for the reduction of the nitro-group in nitrobenzene and o-nitrophenol, but in this case does not present any advantage over the sodium sulphide method. Quinones are easily reduced to the corresponding quinols; thus benzoquinone gives quinol, β-naphthoquinone gives β-naphthoquinol, from phenanthraquinone is obtained phenanthraquinol, and anthraquinone yields oxanthranol. Benzil is reduced smoothly to benzoïn.—J. C. C.

Colouring matters in pastry-ware; Use of carbon tetrachloride for the detection of —— forbidden by public health laws. A. Piutti and G. Bentivoglio. XVIIIA., page 1168.

Dyestuffs and extracts; U.S. census of ——. Oil, Paint, and Drug Rep., Oct. 29, 1906. [T.R.]

A VERY important increase in the output of dyestuffs and extracts was recorded in 1905, as compared with 1900. Ninety-eight establishments reported an output valued at $10,893,113, as compared with 77 establishments having an output of $7,350,748 in 1900. The following table shows materials used, by kind, quantity, and cost, and the products, by kind, quantity, and value:—

ENGLISH PATENTS.

Phenylnaphthimidazole or homologues or derivatives thereof; Manufacture of amidooxy sulphonic acids of ——, and of intermediate products. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 21,175, Oct. 18, 1905.

A MONOAZO dyestuff, obtained by combining a diazo compound with a suitable monoaminonaphtholsulphonic acid (*e.g.*, 2:8:6, or 1:8:4), in which the azo group is in the o-position to the amino group in the naphthalene nucleus, is condensed at ordinary or reduced temperatures with a nitro- or aminobenzaldehyde, or a homologue or derivative of one of these, and the product is reduced, *e.g.*, by stannous chloride in hydrochloric acid solution; the result of the reduction is that one diazo component is split off as an amino compound, whilst the residual compound undergoes intramolecular condensation, to form an aminohydroxysulphonic acid of phenylnaphthimidazole. If a nitrobenzaldehyde has been used in the process, the nitro group will be reduced to an amino group. (See also this J., 1906, 215 and 750.)—T. F. B.

Sulphur colours [Sulphide dyestuffs] and a process for making the same. R. B. Ransford, Upper Norwood. From L. Cassella und Co., Frankfort on Maine, Germany. Eng. Pat. 4097, Feb. 19, 1906.

WHEN dehydrothio-p-toluidine, or one of its derivatives

containing more sulphur in the molecule (primuline bases), is heated with sulphur and benzidine or thiobenzidine, yellow substances are obtained, which are converted into soluble dyestuffs dyeing fast yellow shades on cotton, by heating with alkali sulphides or hydroxides. Sixteen kilos. of dehydrothio-*p*-toluidine, 19 kilos. of benzidine, and 70 kilos. of sulphur, are heated for about 12 hours at 210° C. The melt is ground and added to 240 kilos. of sodium sulphide crystals which have been melted, and the mixture heated to 120° or 125° C. until it is soluble in water; it is then diluted with 600 litres of water, and the solution precipitated with 75 kilos. of hydrochloric acid.—T. F. B.

Colouring matters of the anthracene series; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 20,633, Sept. 17, 1906.

THE acetyl derivatives of halogenated 1-aminoanthraquinones are heated either alone, or in presence of a solvent or a condensing agent, whereby they are converted into dyestuffs which dye from the vat, yielding yellow to orange-yellow shades. If the acetyl compounds are heated alone for some time, at temperatures above their melting points, the dyestuffs may be extracted by means of nitrobenzene, or the impurities may be removed from the melt by treatment with sodium hypochlorite. It is preferable, however, to carry out the condensation in presence of a solvent or diluent, such as nitrobenzene or naphthalene, the yield and purity of the dyestuff being thus enhanced. The products are soluble in alkaline hydrosulphite solutions, yielding yellow-brown vats which dye cotton dull brown shades; on washing, these shades become first greenish-yellow and then slowly orange (or more rapidly by treatment with sodium hypochlorite). The dyed fibre becomes blue by treatment with neutral hydrosulphite solutions.
—T. F. B.

UNITED STATES PATENTS.

Colouring matter for producing silk-like or pearl-lustre effects. L. Lilienfeld, Vienna. U.S. Pat. 834,739, Oct. 30, 1906.

SEE Eng. Pat. 14,483 of 1903; this J., 1903, 1345.—T. F. B.

Indigo white; Process of making halogenated ——. P. E. Oberreit, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 835,462, Nov. 6, 1906.

SEE Eng. Pat. 21,746 of 1905; this J., 1905, 1298.—T. F. B.

FRENCH PATENTS.

Anthracene; Production of a new series of derivatives and dyestuffs from ——, *and their application in dyeing and printing* [*Nitrobenzanthrones*]. Badische Anilin und Soda Fabrik. Eighth Addition, dated June 25, 1906, to Fr. Pat. 349,531, Dec. 21, 1904. Under Int. Conv., April 27, 1906.

SEE Eng. Pat. 12,518 of 1906; this J., 1906, 844.—T. F. B.

Dyestuffs; Production of sulphurised vat —— [*Thio-indigo Red, &c.*]. Badische Anilin und Soda Fabrik. Fr. Pat. 367,431, June 25, 1906. Under Int. Conv., May 16, 1906.

THE chlorides of arylthioglycolic acids, $R.S.CH_2.COCl$, when treated with aluminium chloride, undergo intramolecular condensation, hydrochloric acid being eliminated, and compounds of the general formula $R<\begin{matrix}S\\CO\end{matrix}>CH_2$ produced; on oxidation, these latter are readily converted into the corresponding "vat" dyestuffs, which are similar in properties to indigo. The acid chlorides need not be isolated in the first place, the leuco-compound being prepared in one operation from the arylthioglycolic acid by the action of phosphorus oxychloride and aluminium chloride.—T. F. B.

Dyestuffs; Manufacture of new condensation products and leuco-derivatives of sulphurised vat ——. [*Leuco-thioindigo derivatives.*] Badische Anilin und Soda Fabrik. Fr. Pat. 367,709, June 25, 1906. Under Int. Conv., May 26, 1906.

THIOSALICYLIC ACID, or one of its derivatives or analogues, is condensed with formaldehyde, formaldehyde bisulphite, trioxymethylene, &c., and the condensation product heated with alkali; the leuco-derivatives of vat dyestuffs are thus obtained. 154 kilos. of thiosalicylic acid are dissolved on the water-bath with 100 kilos. of 40 per cent. formaldehyde, three kilos. of hydrochloric acid are added, and the heating is continued until a thick mass is obtained; the solid product is separated, washed, dried, and heated with 600 kilos. of alkali hydroxide, for about half an hour, at 200°—220° C.—T. F. B.

Dyestuffs; Production of sulphurised vat —— [*Thio-indigo dyestuffs*]. Badische Anilin und Soda Fabrik. Fr. Pat. 367,739, July 4, 1906. Under Int. Conv., June 5, 1906.

THE leuco compounds of thioindigo derivatives (see Fr. Pats. 359,398 and 367,709; this J., 1906, 424 and the preceding abstract) can be converted into the corresponding dyestuffs by treatment with sulphur or sulphur chloride in presence or in absence of a solvent. A red dyestuff is obtained by adding 15 parts of thioindoxyl to 28 parts of melted sulphur; colour formation is complete in a short time, when the dyestuff is extracted by sodium sulphide or hydrosulphite, or by an organic solvent.
—T. F. B.

Aminonaphthols; Process for producing ——. F. Sachs. First Addition, dated June 22, 1906, to Fr. Pat. 359,064, Nov. 2, 1905. Under Int. Conv., Aug. 23, 1905.

AMINONAPHTHOLS may be obtained by heating naphthols or their alkali salts with sodium amide, with or without a diluent (a high boiling point substance not attacked by sodium amide). For example, a mixture of equal parts of β-naphthol and naphthalene is heated with one-fourth of its weight of sodium amide, at 220° C., for two hours; the melt is poured into water and acidified, the naphthalene distilled off by means of steam, the unaltered β-naphthol filtered off, and the 1.6-aminonaphthol precipitated. By similar means 1.5-aminonaphthol may be obtained from α-naphthol. When no diluent is used, the temperature of the melt should not exceed 200°—210° C. (See also this J., 1906, 369.) Two errors occur in the original patent (*loc. cit.*, col. 2, lines 23 and 24): "2.5-aminonaphthol" should read "5.2-aminonaphthol."—T. F. B.

Dyestuffs; Production of new mordant monoazo ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 367,504, June 28, 1906. Under Int. Conv., Dec. 19, 1905.

DIAZO derivatives of *o*-aminophenol derivatives containing a nitro group, or a halogen group, or both, but not containing a sulphonic acid group, are combined with 2-arylamino-5-naphthol-7-sulphonic acids. (5-nitro-4-chloro-2-aminophenol, which is claimed in Fr. Pat. 365,415 of 1906, this J., 1906, 923, is excepted.) The resulting dyestuffs dye wool from acid baths in red to violet shades, which are modified by chroming, to blues, violets, and blacks.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 1092.)

Wool; Chlorination of ——. L. Vignon and J. Mollard. (See Knecht, this J., 1892, 131.) Bull. Soc. Ind. Mulhouse, 1906, 76, 254—262.

SAMPLES of wool were submitted to the action of chlorine under the following conditions: (1) Chlorine gas: (*a*) dry at the ordinary temperature and at 50° C.; (*b*) moist, at the ordinary temperature and at 50° C. (2) Chlorine

water in neutral, acid, and alkaline solution. (3) Bleaching powder; the samples being in one set of experiments afterwards treated with sodium bisulphite. The wool was afterwards dyed with Orange I., and also with Methyl Violet. Under these conditions, wool acquires certain altered properties: (1) it loses weight, and the elasticity and tenacity are diminished; (2) it is moistened very easily, and gives deeper and more brilliant shades on dyeing. The authors reject the hypothesis of a direct combination of wool and chlorine, as free chlorine can be detected in the wool by the usual reagents. When treated with sodium bisulphite, which destroys the free chlorine, the wool retains its new properties. The action of the chlorine appears to consist in reacting with the organic substances to form hydrochloric acid and oxidation products by which the molecule is changed and the weight altered. This action may, in certain cases, extend to the ultimate decomposition of the albuminoid constituents, with formation of ammonia, oxalic acid, &c. On the large scale the treatment with chlorine is carefully regulated. It is, however, sufficient to destroy the most prominent parts of the wool-scales, and on this account, apparently, the tendency of the wool to felt and to shrink, is much diminished. Lastly, the increased affinity of chlorinated wool for dyestuffs may be due to an augmentation of its acidic and basic properties, owing to the rupture of some of the chains of amino-acids.—J. C. C.

English Patents.

Textile fibre from reeds or the like; Method of obtaining ——. C. de Hatvany-Deutsch, Budapest, Austria-Hungary. Eng. Pat. 21,768, Oct. 26, 1905.

See Fr. Pat. 358,828 of 1905; this J., 1906, 372.—T. F. B.

Silk; Manufacture of artificial ——. J. E. Bousfield, London. From La Soc. Anon. Fabr. de Soie Artificielle de Tubize, Belgium. Eng. Pat. 3,025, Feb. 7, 1906.

To unwind skeins of silk in an almost perfect manner, when used by manufacturers, the reeling is effected by passing the silk from an ordinary reel, upon which it is wound, to a measuring reel, thus forming the silk into skeins of given length directly without an intermediate winding.—D. B.

Dressing or sizing for yarns and other textile materials. L. Paechtner, London. Eng. Pat. 15,300, July 5, 1906.

In preparing dressings by boiling flour with water in presence of acids or alkalis, the finished base has to be carefully neutralised before it can be used, whilst by treating starch paste with a solution of chloride of lime, a calcium starch compound is formed. A more useful and economical product is obtained by replacing the above substances by chlorine water or a solution of sodium or potassium hypochlorite, although when the former is used, the solution has to be carefully neutralised, by an alkali before application.—D. B.

Silk, artificial; Apparatus for the manufacture of ——. E. Thiele. Fr. Pat. 367,980, July 11, 1906. Under Int. Conv., Oct. 26, 1905.

See Eng. Pat. 16,078 of 1906; this J., 1906, 924.—T. F. B.

Scouring, dyeing, or otherwise treating fabrics, textile materials, and other similar material; Apparatus for ——. M. Nicholas. Fr. Pat. 368,017, June 23, 1906.

See Eng. Pat. 23,509 of 1905; this J., 1906, 1090.—T. F. B.

Fabrics; Apparatus for steaming, treating, and drying ——. Mather and Platt, Ltd. Fr. Pat. 367,911, July 9, 1906. Under Int. Conv., Aug. 4, 1905.

See Eng. Pat. 15,951 of 1905; this J., 1906, 586.—T. F. B.

Drying apparatus, with arrangement for washing, impregnating, dycing, heating, or cooling the material. Aktiebolaget Separator. Fr. Pat. 368,119, July 17, 1906.

See Eng. Pat. 16,001 of 1906; this J., 1906, 1081.—T. F. B.

Printing of fabrics; Machine for the ——. W. Pickup and W. Knowles. Fr. Pat. 367,837, July 6, 1906. Under Int. Conv., April 26, 1906.

The claim is for a printing machine fitted with an arrangement of cams and levers whereby the printing rollers can be removed from contact with the material, so as to cause intermittent printing.—A. B. S.

Finishing material for braids, laces, or fabrics in horsehair or artificial silk. P. Forest. Fr. Pat. 361,759, Sept. 9, 1905.

A hot aqueous solution of gelatin or other albuminous matter is prepared, to which is added at least an equal amount of acetic acid. After cooling, alcohol is added. This liquid is applied to the materials in a thin layer, and allowed to dry in the air, a hot iron being finally passed over the surface to render it uniform.—A. B. S.

Finishing soap [for textiles and paper]; Manufacture of a ——. E. Agostini. Fr. Pat. 361,772, Sept. 16, 1905. XII., page 1160.

Cotton impregnated with methylene ditannate [Antiseptic fabrics]; Manufacture of ——. W. Merck. Fr. Pat. 367,725, July 4, 1906. Under Int. Conv., Feb. 27, 1906.

The cotton material is treated for about half an hour in a boiling concentrated solution of tannin. It is dried, and then introduced, first into a bath of tartar emetic, and then into a cold bath containing 10 parts of formaldehyde (40 per cent.), 10 parts of common hydrochloric acid, and 100 parts of water. The material is finally washed with soap and dried.—A. B. S.

Half-wool fabrics impregnated with methylene ditannate [Antiseptic fabrics]; Manufacture of ——. W. Merck. Fr. Pat. 367,726, July 4, 1906. Under Int. Conv., July 7, 1905.

The material is treated for half an hour with a boiling concentrated solution of tannin, and then washed in cold water in order to remove the excess of the tannin from the cotton. The material is then treated in a cold bath containing 15 parts of formaldehyde (40 per cent.) and 15 parts of crude hydrochloric acid per 100 parts of water for 1—1½ hours. It is then washed, pressed, and dried in the air.—A. B. S.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 1096.)

Molybdic acid; Reduction of —— *in solution by molybdenum, and the titration of the reduced solution by means of permanganate.* M. Guichard. Compt. rend., 1906, **143**, 744—746.

When neutral or slightly acid solutions of molybdic acid are reduced by means of metallic molybdenum, the blue oxide of molybdenum (molybdenum molybdate) is formed. If, on the other hand, the solutions are strongly acid, containing more than 200 grms. of hydrogen chloride or 500 grms. of sulphuric acid per litre, the reduction goes further, and the brown oxide is obtained. To this oxide the formula MoO_2 is usually assigned. From the author's analysis of the brown solution it appears, however, that this brown oxide has a composition corresponding to Mo_2O_5. The molybdenum was determined in the brown solution by evaporation to dryness and ignition of the residue to constant weight; the oxygen was determined by titration with permanganate in an atmosphere of hydrogen.—A. G. L.

Alkali carbonates; Causticising of —— *by lime.* M. Le Blanc and K. Novotny. Z. anorg. Chem., 1906, **51**, 181—201.

The authors have determined by direct as also by conductivity methods the solubility of calcium carbonate in water at 18° and 100° C. The actual amounts dissolved at these temperatures are 13 and 21 mgrms. per litre respectively; but as 65 and 72 per cent. of these amounts respectively are hydrolysed, the amounts actually existing in solution as carbonate are 4 mgrms. per litre at 18°, and nearly 6 mgrms. per litre at 100° C. With the aid of these data and those already existing for the solubility of calcium hydroxide, the authors have calculated the equilibrium constants for the reaction of calcium hydroxide on potassium or sodium carbonate; and they have also carried out direct experiments, starting both from alkali carbonate and lime and from alkali hydroxide and calcium carbonate. The results, given in very great detail in the paper, are summarised below:—

Temp. °C.	Solution used.	Percentage of total alkali converted into hydroxide.
100	$N/1$-Na_2CO_3	99·1
100	$2N$-Na_2CO_3	97·2
100	$3N$-Na_2CO_3	93·6
150	$2N$-Na_2CO_3	97·2
150	$3N$-Na_2CO_3	93·3
18	$N/1$-K_2CO_3	98·1
18	$3N$-K_2CO_3	92·1
100	$N/1$-K_2CO_3	98·8
100	$2N$-K_2CO_3	97·3
100	$3N$-K_2CO_3	92·8

Temperatures (and also pressure) are practically without influence on the final result; the speed of reaction is perhaps greater at higher temperatures, but the experiments show that equilibrium is in all cases rapidly reached. None of the various patents that have been taken out for working at high temperatures or increased pressures have therefore had any scientific foundation, except in so far as they all supplied the conditions for rapid work—high temperature, thorough agitation, considerable excess of lime. On the other hand, the universal industrial practice of not working with a too concentrated solution of alkali carbonate is justified both by the theory of the process and by the experimental results.—J. T. D.

Aluminium phosphate; Transformation of volcanic rocks into —— *under the influence of substances of physiological origin.* A. Lacroix. Compt. rend., 1906, **143**, 661—664.

Large deposits of aluminium phosphate are found on the island of St. Thomas and other islands in the gulf of Guinea. This results from the reaction on the trachytes and other volcanic rocks of the islands, of the dung of sea-fowl. Phosphates formed in a similar manner from limestone rocks are well known, but this decomposition of silicious rocks seems not to have been before observed. The alkalis contained in the rocks are not present in the phosphate, having no doubt been washed out by the copious rains to which the islands are subject.—J. T. D.

Potassium persulphate; Behaviour of —— *towards some saline solutions.* R. Pajetta. Gaz. chim. ital., 1906, **36** [2], 298—304.

The solubility of potassium persulphate in water and in saturated solutions of different salts at 12° C. was determined; the results are expressed in grms. per 100 c.c.: Water, 3·181; sodium sulphate, 5·987; sodium bisulphate, 8·72; disodium phosphate, 4·693; borax, 3·795; sodium nitrate, 19·143; sodium carbonate, 5·613; sodium bicarbonate, 4·947; potassium sulphate, 0·792; potassium bisulphate, 0·329; potassium nitrate, 0·896; potassium carbonate, 0·0118; potassium bicarbonate, 0·309; magnesium sulphate, 2·961, and calcium sulphate, 3·37. It will be seen that the solubility of potassium persulphate is greater in presence of sodium salts and less in presence of potassium salts than in pure water. The solubility in solutions of sodium salts is a function of the concentration of sodium in the solution, equal volumes of solutions containing equivalent quantities of different sodium salts dissolving equal amounts of persulphate. According to the author these results show that in presence of sodium salts double decomposition takes place according to the equation: $K_2S_2O_8 + Na_2SO_4 = Na_2S_2O_8 + K_2SO_4$. (See also this J., 1906, 1068.)—A. S.

Barium ferrate; Properties of ——. E. Baschieri. Gaz. chim. ital., 1906, **36** [2], 282—286.

Barium ferrate, $BaFeO_4.H_2O$, is scarcely acted upon by sulphuric acid at the ordinary temperature, but is attacked immediately by hydrochloric and nitric acids. With dilute hydrochloric acid, chlorine is evolved, and the solution is coloured red; after some days the evolution of chlorine ceases, and the red colour disappears; barium chloride and ferric chloride are found in the solution. A red coloration is also produced when the ferrate is decomposed by very dilute nitric (evolution of ozone), acetic (evolution of carbon dioxide), oxalic, formic, citric, and salicylic acids. No red coloration is produced when the ferrate is decomposed by carbonic acid or by hydrocyanic acid; in the latter case, metallic iron and barium ferricyanide are formed. It is probable that the red coloration is due to the presence of FeO_4'' anions in solution, the properties of barium ferrate resembling those of peroxides.—A. S.

Carbon monoxide; Action of —— *on steam at red heat, and action of hydrogen on carbon dioxide.* A. Gautier. Bull. Soc. Chim. 1906, **35**, 929—934.

Boudouard (Bull. Soc. Chim., 1901, **25**, 484) determined the ratio, CO/CO_2, in the equilibrium between carbon monoxide, steam, carbon dioxide, and hydrogen at different temperatures; and Hahn (Z. physik. Chem., 1903, **42**, 705; **44**, 513; 1904, **48**, 735; this J., 1903, 1038) determined the coefficient, $K = \frac{CO \times H_2O}{CO_2 \times H_2}$, at different temperatures. The author shows that when a current of carbon monoxide, mixed with a varying excess of steam is passed through a porcelain tube heated to 1200°—1250° C.,

at the rate of about 1 litre of the mixed gases per hour, or when a dry mixture of equal volumes of carbon dioxide and hydrogen is similarly treated at 1300°, the reaction proceeds until the volume of hydrogen is about double that of carbon monoxide. The reactions correspond with the equations:

$$3CO + 3H_2O = CO + H_2O + 2H_2 + 2CO_2.$$
$$3CO_2 + 3H_2 = CO + H_2O + 2H_2 + 2CO_2.$$

Under these conditions, any mixture of carbon monoxide, steam, hydrogen, and carbon dioxide tends towards the composition, $CO + H_2O + 2H_2 + 2CO_2$. Small quantities of formic acid, but no formaldehyde, are produced. These results are discussed with reference to the composition of volcanic gases, and attention is directed to the occurrence of formic acid in certain hot mineral springs.—A. T. L.

Borax; Production of ——. The United States Mineral Resources, 1905. [T.R.]

THE production of borax during 1905 was almost entirely confined to California. Only small quantities are ever taken from the marshes of Nevada during the summer months. The total output of crude borax in the United States for 1905 was 46,334 short tons, valued at $1,019,154, as against 45,647 tons, $698,810, in 1904, an increase of 687 tons, $320,334. From 2 to 4 tons of crude borax are required to make 1 ton of pure anhydrous boric acid. When the crude product, worth at the mines from $15 to $50 per ton, is refined, it is worth on the market from $120 to $140 per ton. No pure borax is shipped, about six-sevenths of the total product being only 25 per cent. ore. The crude material, as it comes from the ground, varies in boric acid content from about 5 per cent. to about 35 per cent.

Uranium sodium acetate; U.S. Customs Decision. Oil, Paint, and Drug Rep., Oct. 22, 1906. [T.R.]

THE protest of the importers was sustained regarding the duty on merchandise invoiced as "uranium and sodium acetate." The importation was assessed at the rate of 45 per cent. *ad valorem*, under paragraph 3 of the Tariff Act, as a chemical compound, and was claimed to be free, under paragraph 691 of the same Act. From the evidence presented, the merchandise was found to be a double salt of uranium, and therefore entitled to free entry, as claimed. The decision of the collector was accordingly reversed.

Gases; Process and apparatus for separating —— [e.g., oxygen from the air]. A. A. Humphrey, London. Eng. Pat. 14,809, July 18, 1905.

THE process is based upon the different solubilities of gases in water, and is intended especially for separating oxygen from the air. Water flows from a reservoir into a funnel disposed above the open funnel-shaped top of a tall vertical pipe. The upper funnel has a piece of gauze stretched across the bottom in order to break up the stream of water. Air is drawn in by the water through the space between the funnels, and as the mixture of air and water descends, the nitrogen and oxygen are dissolved according to their respective solubilities, and to the pressure (height of the column of water). The lower end of the pipe opens into a closed tank, from the top of which a second pipe ascends for the escape of undissolved gases. The water containing the dissolved gases is withdrawn from near the bottom of the tank, and forced by a circulating pump up a third pipe to the water reservoir at a higher level than the top of the first vertical pipe. In the reservoir, owing to the low pressure, the dissolved gases (air enriched in oxygen) escape, and are withdrawn, and either utilised directly or passed through another similar apparatus, or through the same apparatus again. The water is used over again. Various modifications of the apparatus are described.—A. S.

Oxygen gas; Means for generating ——. R. von Foregger, New York. Eng. Pat. 11,979, May 22, 1906. Under Int. Conv., Feb. 8, 1906.

FRENCH PATENTS.

Sulphuric acid; Apparatus for the concentration of ——. A. Gaillard. Fr. Pat. 367,376, June 23, 1906.

THE acid to be concentrated is sprayed from an atomiser at the top of a cylindrical tower. In its passage down the tower it meets hot products of combustion from an auxiliary stove; these gases enter near the bottom of the tower and emerge by a pipe in the top, which leads them to the chimney, through a scrubbing tower filled with coke. Just below the inlet pipe for the hot gases is placed a perforated plate on which the acid collects, and through which it drops into a shallow trough at the base of the tower. This trough is cooled by a spiral cold water pipe inside it, and outside it another cold water pipe. The top of the tower, made of lead, meets the walls in a hydraulic seal; the walls are of stone, with or without an outer coating of lead.—A. G. L.

Alumina; Process for the preparation of pure ——. H. Arsandaux. Fr. Pat. 361,766, Sept. 13, 1905.

LYES of sodium aluminate, such as those occurring in the lixiviation of the product obtained by furnacing a mixture of bauxite with sodium carbonate, and containing silicates, are treated with sodium carbonate solution, and then with an equivalent quantity of milk of lime, or with finely divided or recently precipitated calcium carbonate, in order to form calcium silico-aluminate, which is separated by filtration. Aluminium hydroxide is then precipitated from the cleared solution by carbon dioxide in the usual manner.—E. S.

Aluminium hydroxide and aluminates; Process for the manufacture of ——. Chem. Fabr. Griesheim-Elektron. Fr. Pat. 367,728, July 4, 1906. Under Int. Conv., Nov. 24, 1905.

BAUXITE is heated to a temperature between 180° and 200° C. in an open vessel, and a strong boiling hot solution of potassium hydroxide (in the proportion indicated by $Al_2O_3:Na_2O$, or $K_2O = 1:1·3—1·5$) is gradually added. The heating is continued for half an hour or more, after which the potassium aluminate formed is extracted and

treated as usual. Sodium hydroxide may be substituted for the potassium hydroxide, but in this case a final heating to about 500° C. is necessary.—A. G. L.

Aluminium compounds; Process for the manufacture of ——. E. L. Rinman. Fr. Pat. 367,756, July 4, 1906.

Minerals containing aluminium, such as aluminium silicates, bauxite, kaolin, and felspar, are finely powdered and intimately mixed with an ammonium salt, preferably ammonium sulphate or chloride. The mineral may be used in the crude state or after a preliminary calcination. The mixture is then heated to a temperature at which the ammonium salt is dissociated, an aluminium salt and free ammonia being formed. The aluminium salt is leached out of the residue with water; aluminium hydroxide may be made from it by treating it with the ammonia evolved during the reaction, the ammonium salt being regenerated. If alkalis are present in the mineral, their salts will also be found in the solution. When ammonium chloride is employed as the decomposing agent, sublimed aluminium chloride may be obtained from the mixture by first heating under a pressure of 2 to 3 atmospheres at 350° C. until no more ammonia is evolved, and then lowering the pressure whilst maintaining the temperature.—A. G. L.

Hyposulphites [hydrosulphites]; Production of stable ——. Badische Anilin und Soda Fabrik. Fr. Pat. 367,524, June 5, 1906. Under Int. Conv., Nov. 8, 1905.

Calcium hyposulphite, precipitated by sodium hyposulphite from calcium chloride solution, is filtered off, washed with water, and with alcohol, and the alcoholic paste is incorporated with finely powdered quicklime. After removal of the bulk of the alcohol, the mass is dried in a vacuum, and preserved in hermetically closed vessels. Lime may be replaced in the process by the oxides of other alkaline-earth metals, or by the dry hydroxides of alkali metals. Reference is made to Fr. Pat. 300,735 of 1900. (Compare Eng. Pat. 18,852 of 1900; this J., 1901, 988.) —E. S.

Cyanogen compounds; Preparation of —— from vinasse. Chem. Fabr. Schlempe, G.m.b.H. Fr. Pat. 367,502, June 28, 1906. Under Int. Conv., Jan. 16, 1906.

The tar produced in the destructive distillation of vinasse, containing nitrogen, is, according to one process, partially burned with access of air, and the mixture of gases and vapour is passed through a highly heated tube to induce the formation of cyanogen. Another process consists in distilling the tar, without contact of air, direct into a carburetter used in the production of water-gas, the transformation into cyanogen being effected when these vapours and the water-gas traverse the superheater raised to a very high temperature. It is stated that thus the nitrogen in both the tar gases and in the water-gas is transformed into cyanogen, whilst the carbon compounds in the former serve to enrich the latter.—E. S.

Natural salts from mineral waters; Apparatus for extraction of —— by evaporation on a water-bath. J. J. Deprin. Fr. Pat. 367,762, July 4, 1906.

The mineral water, after undergoing a preliminary concentration in an ordinary steam boiler, is heated in a series of rectangular enamelled basins with concave bottoms, supported in a water-bath. The water-bath is heated by a furnace and is provided with a filling hole, a vapour-escape pipe, and an emptying pipe and tap. The contents of the basins are kept in movement by oscillating agitators suspended by hollow arms from a hollow shaft, and the solids are left as crystals in the basins.—W. H. C.

Glucina [Beryllia]; Process for separating —— from alumina and iron by acids and acid salts, especially by carbonic acid and alkali bicarbonates. F. Bran and G. van Oordt. Fr. Pat. 367,861, July 7, 1906. Under Int. Conv., July 15, 1905.

A mixture of the hydroxides of glucinum [beryllium] aluminium, and iron is treated with a solution of sodium carbonate and with carbon dioxide; or with sodium bicarbonate solution, the proportion being maintained of at least 1 mol. of the sodium salt to one of the glucinum hydroxide. Under these conditions, the glucina dissolves Or, the hydroxides may be treated with an alkaline lye, the solution being filtered from any undissolved iron hydroxide, and carbon dioxide passed through until the alkali is bicarbonated, when the glucina alone remains in solution.—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 1096.)

English Patent.

Enamelling or glazing metallic and other surfaces; Process of ——. W. Atkinson, Shipley, Yorks, and J. Smith, Bradford. Eng. Pat. 12,554, May 30, 1906.

The metallic articles to be coated are first cleaned with sulphuric acid, after which a flux is applied. This consists of 130 parts of white opal cullet, 20 of sodium bicarbonate, and 12 of boric acid, for wrought-iron or steel articles; for cast iron, a flux consisting of 130 parts of white opal cullet, 25 of sodium bicarbonate, and 13 of boric acid, is used. In either case the flux is first melted, run into water, and powdered before it is applied. The coated article is then dried and fired. The cold article is covered with a second coat of white opal cullet, or flint glass, or soda glass, also previously melted, run into water, and powdered. The second coat is allowed to dry, after which the article is again fired, preferably to a temperature just below the melting point of the metal. Broken porcelain may be substituted for the glass, but in this case the porcelain is heated only to redness, not fused, before it is thrown into water and powdered. Pottery may be enamelled in the same way.—A. G. L.

United States Patent.

Glass plates; Manufacture of ——. B. C. White, Chicago, Ill. U.S. Pat. 835,148, Nov. 6, 1906.

The method described of manufacturing glass plates consists in depositing a mass of glass upon a table between two rollers, moving the rollers along the table to spread a portion of the glass into a sheet, and then reversing the direction of movement of the two rollers and introducing a fabric or web between the portion of glass spread into a sheet and the roller effecting the spreading operation, and by the action of the other roller, spreading the remaining portion of glass into a sheet over and upon the fabric or web, and the sheet previously spread. The axes of the two rollers are linked together so that the rollers move forwards and backwards as a single body over the table. (See also U.S. Pats. 805,609 and 805,610 of 1905; this J., 1906, 20.)—W. C. H.

French Patents.

Glass-melting furnaces; The "monolithic" tank and its application to ——. J. Lecomte-Falleur et Cie. First Addition, dated June 18, 1906, to Fr. Pat. 346,012, Sept. 2, 1904. (See Eng. Pat. 19,067 of 1904; this J., 1905, 91).

This addition to the principal patent is for an arrangement for the continuous supply of material to the "monolithic" tank to avoid the repeated cooling of the mass of molten glass by intermittent additions of cold material, to economise material, to protect the "siège" and the tanks, and prevent clogging of the regenerators by molten material dripping into them. The arrangement suggested is either a trough or boat to contain the materials, which is placed over the melting compartment of the tank, and provided with an opening for the molten material to fall into the compartment, or a shoot, on which the materials are gradually melted by the heat of the furnace, and slide into the melting compartment.—W. C. H.

Enamels; Process for the manufacture of vitrifiable ——. P. Wagret. Fr. Pat. 367,613, April 12, 1906. Under Int. Conv., March 17, 1906.

The vitrifiable enamels are produced by the employment of

the following materials:—For red: Minium, Paris red, grey earth ("Terre grise"), borax. For black: indigo blue. For white: fluorspar.—W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 1098.)

Wood; Effect of moisture on the strength and stiffness of ——. United States Forest Service Rep. Eng. and Min. J., Nov. 10, 1906, 865.

THE United States Forest Service has studied this subject, with the following results:—The relation of moisture to strength follows a definite law. Proper drying greatly increases the strength of all kinds of wood, the amount of increase depending upon the species and the degree of dryness. For example, the strength of a piece of unseasoned red spruce may be increased over 400 per cent. by a thorough drying at the temperature of boiling water. Strength decreases again, however, as the wood reabsorbs moisture. Air-dried wood, protected from the weather and containing 12 per cent. of moisture, is from 1·7 to 2·4 times stronger than when green, according to the species. Stiffness is also increased by drying. These conclusions, however, are drawn from small-sized pieces, not exceeding 4 by 4 in. cross-section. Large timbers require years of drying before the moisture is reduced to the point at which strength begins appreciably to increase. More or less "checking" always occurs when large timbers dry, and if this "checking" be excessive it may cause enough weakness to counter-balance the strength gained by the drying. Consequently it is not safe to assume that the average strength of large so-called seasoned timbers is much greater than that of green or wet ones. The fibre-saturation point of a number of species has been determined. This point, which varies with conditions and species of wood, designates the percentage of water which will saturate the fibres of the wood. It has been found that, under normal conditions, a given kind of wood fibre will absorb a definite amount of moisture; additional water simply fills the pores of the wood. Only that water which permeates the wood fibre has an influence upon strength. For the following species, the saturation point occurs at the given percentage of moisture based on the dry weight of the wood: Longleaf pine, 25; red spruce, 31; chestnut 25; loblolly pine sapwood, 24; red gum, 25; red fir, 23; white ash, 20·5; Norway pine, 30; Western tamarack, 30 per cent. Prolonged soaking in cold water does not reduce the strength of green wood below that at its fibre-saturation point, provided it remains in perfect condition. When wood has been dried and is resoaked, it becomes slightly weaker than when green. Wood soaked in heated water absorbs more moisture. This causes a reduction in strength and stiffness, as is seen in wood steamed for bending.

ENGLISH PATENTS.

Stone, artificial, from slag; Manufacture of ——. W. Schumacher, Osnabrück, Germany. Eng. Pat. 18,806, Sept. 18, 1905.

IN this process for the manufacture of artificial stone, slag is first subjected to a coarse disintegrating process, and after being heated by steam, and with or without a small admixture of lime, but without admixture of other silicious material, is pressed into blocks, which are ready for use within a short time after their production. The blocks so prepared may be subjected to a hardening process by means of steam under pressure.—W. C. H.

Stones, artificial, and other plastic articles; Manufacture of —— . W. J. Apperley and F. J. D. Hullinghorst, London. Eng. Pat. 17,569, Aug. 3, 1906.

Two parts by weight of a solution of lead acetate at 10°—20° B. are added to 1 part of ammonia (sp. gr., 0·880). The clear solution obtained on standing (10 to 30 per cent.) is added to magnesium chloride solution (300 parts) at 25°—35° B. Of the mixed solution, 1 part is added to ¼—1 part of burnt magnesite, various organic or inorganic substances being added as filling materials. Liquid oils, or fats, may be used for this purpose, after mixing them with a solution obtained by acting with caustic potash solution (at 15°—35° B.) on powdered resin. To produce a material resisting moisture, cold, and heat, bituminous materials or tar may be added to the solution obtained on dissolving barium dioxide in hydrochloric acid, and this mixture used as filling material.—A. G. L.

Drying; Apparatus for ——, *suitable for bricks, timber, and other purposes.* W. B. Hughes, London. Eng. Pat. 21,816, Oct. 26, 1905.

A DRYING chamber, provided with doors and shelves to support the materials to be dried, is built over a trench. In the upper part of the latter a number of horizontal pipes are arranged through which steam or some other heating medium can be passed. A blast of air is delivered by a fan into a perforated pipe placed below the heating pipes, the perforations being made progressively larger the further they are from the point at which the air enters. The air passes up, around and between the heating pipes, and then around and between the materials on the shelves of the drying chamber, and finally escapes along with the vapour given off through openings in the sides.—W. H. C.

Stucco; Manufacture of ——. J. Y. Johnson, London. From R. Koepp und Co., Oestrich on Rhine, Germany. Eng. Pat. 4503, Feb. 23, 1906.

SEE Fr. Pat. 363,564 of 1906; this J., 1906, 848.—T. F. B.

UNITED STATES PATENTS.

Clay products; Dryer for ——. R. W. Lyle, New York. U.S. Pat. 834,584, Oct. 30, 1906.

THE dryer consists of one or more drying tunnels or compartments. The products of combustion from a system of kilns are conveyed to a main flue chamber, which extends across one end of the drying compartments, and is contained entirely within the dryer, in which the radiating top of the flue is directly exposed. Longitudinal heat-radiating flues are arranged in the drying compartments, and are connected with the main flue chamber, from which they can be independently closed. The ends of the longitudinal flues that enter the main flue chamber are supported by the wall of the main flue and a second wall a little outside it, the space between the walls being filled with packing to form a loose-joint connection. Forced draught can be produced in the flue chamber, and in any of the longitudinal flues that are in open communication with it at the time. The flues are provided with openings, that can be closed with covers, when necessary, for the passage of products of combustion from the flues.—W. C. H.

[*Mortar*] *Composition of matter.* M. W. Beique, Colorado Springs, Colo. U.S. Pat. 834,252, Oct. 30, 1906.

THE composition described consists of unslaked lime (100 lb.), plaster of Paris (200 lb.), and tailings from ore that has been treated by a cyanide process (2000 lb.). These are mixed together with enough water to give the desired consistency to the mass, and common sand is added "to overcome excess of slimes" in the tailings; hair or fibre may also be added.—W. C. H.

Cement; Manufacture of hydraulic ——, *and apparatus therefor.* B. Enright, South Bethlehem, Pa. U.S. Pat. 834,374, Oct. 30, 1906.

THE process described consists in passing the highly heated gaseous products of combustion and decomposition issuing from a rotary cement kiln through a charge of cement-forming materials in a vertical kiln, to which the sensible heat of the gases is imparted. The whole or part of the carbon dioxide produced in the vertical kiln is reduced to carbon monoxide and returned to the vertical kiln, and there again burned to the dioxide while calcining the charge of material in the kiln. The apparatus comprises a rotary kiln connected at its upper end with the

treated as usual. Sodium hydroxide may be substituted for the potassium hydroxide, but in this case a final heating to about 500° C. is necessary.—A. G. L.

Aluminium compounds; Process for the manufacture of ——. E. L. Rinman. Fr. Pat. 367,756, July 4, 1906.

Minerals containing aluminium, such as aluminium silicates, bauxite, kaolin, and felspar, are finely powdered and intimately mixed with an ammonium salt, preferably ammonium sulphate or chloride. The mineral may be used in the crude state or after a preliminary calcination. The mixture is then heated to a temperature at which the ammonium salt is dissociated, an aluminium salt and free ammonia being formed. The aluminium salt is leached out of the residue with water; aluminium hydroxide may be made from it by treating it with the ammonia evolved during the reaction, the ammonium salt being regenerated. If alkalis are present in the mineral, their salts will also be found in the solution. When ammonium chloride is employed as the decomposing agent, sublimed aluminium chloride may be obtained from the mixture by first heating under a pressure of 2 to 3 atmospheres at 350° C. until no more ammonia is evolved, and then lowering the pressure whilst maintaining the temperature.—A. G. L.

Hyposulphites [hydrosulphites]; Production of stable ——. Badische Anilin und Soda Fabrik. Fr. Pat. 367,524, June 5, 1906. Under Int. Conv., Nov. 8, 1905.

Calcium hyposulphite, precipitated by sodium hyposulphite from calcium chloride solution, is filtered off, washed with water, and with alcohol, and the alcoholic paste is incorporated with finely powdered quicklime. After removal of the bulk of the alcohol, the mass is dried in a vacuum, and preserved in hermetically closed vessels. Lime may be replaced in the process by the oxides of other alkaline-earth metals, or by the dry hydroxides of alkali metals. Reference is made to Fr. Pat. 300,735 of 1900. (Compare Eng. Pat. 18,852 of 1900; this J., 1901, 988.) —E. S.

Cyanogen compounds; Preparation of —— from vinasse. Chem. Fabr. Schlempe, G.m.b.H. Fr. Pat. 367,502, June 28, 1906. Under Int. Conv., Jan. 16, 1906.

The tar produced in the destructive distillation of vinasse, containing nitrogen, is, according to one process, partially burned with access of air, and the mixture of gases and vapour is passed through a highly heated tube to induce the formation of cyanogen. Another process consists in distilling the tar, without contact of air, direct into a carburetter used in the production of water-gas, the transformation into cyanogen being effected when these vapours and the water-gas traverse the superheater raised to a very high temperature. It is stated that thus the nitrogen in both the tar gases and in the water-gas is transformed into cyanogen, whilst the carbon compounds in the former serve to enrich the latter.—E. S.

Natural salts from mineral waters; Apparatus for extraction of —— by evaporation on a water-bath. J. J. Deprin. Fr. Pat. 367,762, July 4, 1906.

The mineral water, after undergoing a preliminary concentration in an ordinary steam boiler, is heated in a series of rectangular enamelled basins with concave bottoms, supported in a water-bath. The water-bath is heated by a furnace and is provided with a filling hole, a vapour-escape pipe, and an emptying pipe and tap. The contents of the basins are kept in movement by oscillating agitators suspended by hollow arms from a hollow shaft, and the solids are left as crystals in the basins.—W. H. C.

Glucina [Beryllia]; Process for separating —— from alumina and iron by acids and acid salts, especially by carbonic acid and alkali bicarbonates. F. Bran and G. van Oordt. Fr. Pat. 367,861, July 7, 1906. Under Int. Conv., July 15, 1905.

A mixture of the hydroxides of glucinum [beryllium] aluminium, and iron is treated with a solution of sodium carbonate and with carbon dioxide; or with sodium bicarbonate solution, the proportion being maintained of at least 1 mol. of the sodium salt to one of the glucinum hydroxide. Under these conditions, the glucina dissolves Or, the hydroxides may be treated with an alkaline lye, the solution being filtered from any undissolved iron hydroxide, and carbon dioxide passed through until the alkali is bicarbonated, when the glucina alone remains in solution.—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 1096.)

English Patent.

Enamelling or glazing metallic and other surfaces; Process of ——. W. Atkinson, Shipley, Yorks, and J. Smith, Bradford. Eng. Pat. 12,554, May 30, 1906.

The metallic articles to be coated are first cleaned with sulphuric acid, after which a flux is applied. This consists of 130 parts of white opal cullet, 20 of sodium bicarbonate, and 12 of boric acid, for wrought-iron or steel articles; for cast iron, a flux consisting of 130 parts of white opal cullet, 25 of sodium bicarbonate, and 13 of boric acid, is used. In either case the flux is first melted, run into water, and powdered before it is applied. The coated article is then dried and fired. The cold article is covered with a second coat of white opal cullet, or flint glass, or soda glass, also previously melted, run into water, and powdered. The second coat is allowed to dry, after which the article is again fired, preferably to a temperature just below the melting point of the metal. Broken porcelain may be substituted for the glass, but in this case the porcelain is heated only to redness, not fused, before it is thrown into water and powdered. Pottery may be enamelled in the same way.—A. G. L.

United States Patent.

Glass plates; Manufacture of ——. B. C. White, Chicago, Ill. U.S. Pat. 835,148, Nov. 6, 1906.

The method described of manufacturing glass plates consists in depositing a mass of glass upon a table between two rollers, moving the rollers along the table to spread a portion of the glass into a sheet, and then reversing the direction of movement of the two rollers and introducing a fabric or web between the portion of glass spread into a sheet and the roller effecting the spreading operation, and by the action of the other roller, spreading the remaining portion of glass into a sheet over and upon the fabric or web, and the sheet previously spread. The axes of the two rollers are linked together so that the rollers move forwards and backwards as a single body over the table. (See also U.S. Pats. 805,609 and 805,610 of 1905; this J., 1906, 20.)—W. C. H.

French Patents.

Glass-melting furnaces; The "monolithic" tank and its application to ——. J. Lecomte-Falleur et Cie. First Addition, dated June 18, 1906, to Fr. Pat. 346,012, Sept. 2, 1904. (See Eng. Pat. 19,067 of 1904; this J., 1905, 91).

This addition to the principal patent is for an arrangement for the continuous supply of material to the "monolithic" tank to avoid the repeated cooling of the mass of molten glass by intermittent additions of cold material, to economise material, to protect the "siège" and the tanks, and prevent clogging of the regenerators by molten material dripping into them. The arrangement suggested is either a trough or boat to contain the materials, which is placed over the melting compartment of the tank, and provided with an opening for the molten material to fall into the compartment, or a shoot, on which the materials are gradually melted by the heat of the furnace, and slide into the melting compartment.—W. C. H.

Enamels; Process for the manufacture of vitrifiable ——. P. Wagret. Fr. Pat. 367,613, April 12, 1906. Under Int. Conv., March 17, 1906.

The vitrifiable enamels are produced by the employment of

greater as either the chromium or the carbon increases. The mechanical properties of these steels are in every case similar to those of the corresponding nickel steels, the effect of the chromium being, however, to raise the breaking stress and the elastic limit without sensibly lessening the elongation or the resistance to shock; but the chrome-nickel steels containing carbide (a structure not met with in nickel steels under the same conditions) are brittle, though having medium values for elongation. *Quenching* a pearlitic chrome-nickel steel increases the breaking stress and elastic limit to a greater extent than in the corresponding nickel steel or chromium steel; it produces little effect on a martensitic chrome-nickel steel, softens a γ-iron steel slightly whilst not sensibly changing its micrographic structure, and is without action on a carbide steel unless the initial temperature be above 1200° C. *Reheating* softens slightly all the chrome-nickel steels, without sensibly altering their structure. *Cementation* affects them as it does the nickel steels. The only chrome-nickel steels which seem capable of industrial application are the pearlitic and γ-iron steels; the former are much harder after quenching, and the latter have a much higher elastic limit than the corresponding nickel steels. By cementation, a pearlitic chrome-nickel steel yields a steel with an outer martensitic shell much harder than that yielded by a nickel steel under similar treatment.—J. T. D.

Ammonia-copper-cyanide process. [*Gold extraction.*] E. Le Gay Brereton. Inst. Min. and Met., Bulletin No. 26, 27—31.

THE author shows that when an ammoniacal copper solution is titrated with an alkali cyanide, a certain amount of free cyanide is indicated by silver nitrate, not only when the solution is decolorised, but at all stages of the titration. This is the case both with ammonium cyanide and potassium cyanide, and appears to be due to ordinary mass action, a greater excess of "ammonium hydrate" in the solution causing a greater excess of free cyanide. This free cyanide always increases, on standing, up to a certain point (two days), after which it remains constant, the increase possibly being due to the breaking-down of the last of the cupric cyanide. The addition of more ammonia to a decolorised solution does not cause a return of the blue colour even after prolonged standing (three months), unless the free cyanide is also removed. In extracting gold by means of the ammonia-copper-cyanide process, the best results with a 0·25 per cent. solution of potassium cyanide were obtained in the presence of only 0·11 per cent. of ammonia, from which it appears that the efficiency depends mainly upon the quantity of cyanogen liberated by the decomposition of the cupric cyanide to cuprous cyanide, and not merely upon the protection of the potassium cyanide by the ammonia.—A. G. L.

Copper-palladium alloys. R. Ruer. Z. anorg. Chem. 1906, **51**, 223—230.

COOLING-CURVES of alloys of palladium and copper have shown the authors that while the two metals may be melted together in all proportions, the alloys are simple mixtures, and there is no evidence of any compound of the two metals, or even of a eutectic. Alloys containing less than 20 per cent. of palladium show the colour of the copper they contain, but those containing more palladium are white. The alloys are harder than either of their constituents, the hardest alloy being that which contains equal proportions of the two metals.—J. T. D.

Sulphides; Action of steam on —— at red heat. Formation of native metals. A. Gautier. Bull. Soc. Chim., 1906, **35**, 934—939.

THE action of steam on iron sulphide at incipient red heat proceeds mainly in accordance with the reaction:—

$$3FeS + 4H_2O = Fe_3O_4 + 3H_2S + H_2.$$

With excess of steam and at a higher temperature, sulphur dioxide and free sulphur are formed (Gautier, Bull. Soc. Chim., 1901, **25**, 408). With the sulphides of metals which do not decompose steam at red heat, the action proceeds differently. When steam is passed through a tube in which is placed an earthenware boat containing galena, the latter commences to volatilise at incipient red heat and crystallises with a little lead sulphate in the cooler parts of the tube. After cooling, the boat contains metallic lead with about 2 per cent. of free sulphur. Some free sulphur sublimes, and the only gaseous product is a trace of sulphur dioxide. The reactions which occur are:—

$$3PbS + 2H_2O = 3Pb + 2H_2S + SO_2;$$
$$2H_2S + SO_2 = 2H_2O + 3S;$$
$$PbS + 2SO_2 = PbSO_4 + 2S.$$

These experiments show how a native metal may be formed from its sulphide by the action of steam under conditions similar to those which obtain in the depths of the earth, and indicate one of the sources of the free sulphur emitted from fissures in volcanic rocks. The action of steam on cuprous sulphide at bright red heat yields sulphur dioxide and hydrogen without hydrogen sulphide. The cuprous sulphide is partly reduced to copper. The principal reaction is:—

$$Cu_2S + 2H_2O = 2Cu + SO_2 + 2H_2.$$

A small quantity of free sulphur is produced. The sulphides of silver react even more readily and yield metallic silver, sulphur dioxide, and free sulphur. Native silver occurring with free sulphur, and in some cases with native copper, is probably formed in this manner. A mixture of steam and hydrogen sulphide passed through a tube at bright red heat yields free sulphur, condensed steam containing sulphurous and sulphuric acids with traces of thionic compounds, and a mixture of gases containing from 17 to 10 per cent. of sulphur dioxide and from 83 to 90 per cent. of hydrogen. Thus, steam oxidises metallic sulphides, hydrogen sulphide, and free sulphur at red heat, with the formation of sulphur dioxide and small quantities of sulphuric acid, and it is no longer necessary to assume that atmospheric oxygen penetrates deeply into the earth's crust in order to explain the presence of these compounds in volcanic gases and in springs of volcanic origin.—A. T. L.

Hydrogen sulphide; Action of —— on metallic and non-metallic oxides at high temperature. A. Gautier. Bull. Soc. Chim., 1906, **35**, 939—944.

THE action of excess of hydrogen sulphide at bright red heat on the oxides of iron yields iron sulphide, FeS, mixed with a lower sulphide. The resulting gases, after removal of hydrogen sulphide, contain about 11 per cent. of sulphur dioxide and 88 per cent. of hydrogen when ferric oxide is used, and about 83 per cent. of sulphur dioxide and 17 per cent. of hydrogen when the magnetic oxide is employed. The reaction with ferric oxide is represented by the equation:—

$$2Fe_2O_3 + 7H_2S = 4FeS + 3SO_2 + 7H_2.$$

The action of hydrogen sulphide on steam has been described in the preceding paper (see preceding abstract). The action on silica yields silicon sulphide, the oxysulphide $SiO_2.SiS_2$, sulphur dioxide, and hydrogen. With alumina the reaction is:—

$$4Al_2O_3 + 9H_2S = 2Al_2O_3,2Al_2S_3 + 3SO_2 + 9H_2.$$

Natural aluminium silicates react similarly, having part of their oxygen replaced by sulphur, and part of their silica separated as oxysulphide. A mixture of hydrogen sulphide and carbon dioxide at bright red heat yields carbon monoxide, carbon oxysulphide, free hydrogen, and a considerable quantity of water, but no sulphur dioxide. The reaction is:—

$$8CO_2 + 9H_2S = 3COS + 5CO + H_2 + 8H_2O + 6S.$$

The absence of sulphur dioxide is due to the reaction:—

$$2CO + SO_2 = 2CO_2 + S.$$

Carbon oxysulphide has been found from time to time in volcanic gases and in hot springs in volcanic districts. It has probably been frequently overlooked on account of its rapid conversion into hydrogen sulphide and carbon dioxide in the presence of moisture at ordinary temperatures. It is found that all the reactions in which sulphur dioxide is formed at red heat also yield small

quantities of sulphuric acid, which is thus produced without the presence of oxygen, in accordance with the equation:—

$$2SO_3 = SO_2 + O + S.$$

The steam formed by the action of hydrogen or of hydrogen sulphide on carbon dioxide is stated to be sufficient to account for the large quantities emitted by volcanoes, and it may also be the source of the hot springs in their vicinity.—A. T. L.

Power obtainable from metallurgical waste gases. C. Richter. Gasmotorentechnik, 1906, 6, 73—76. Science Abstracts, 1906, 9B, 426—427.

THE author gives a formula whereby the volume of waste gases from blast-furnaces and other metallurgical furnaces can be calculated. In most cases it is impossible to devise any accurate system of measuring the volume of these gases, and estimates of the power which is available are therefore not always trustworthy. The author's method depends upon taking some "critical" element, such as carbon, which is converted during the furnace process into gas, and from the amount of this charged into the furnace during a given time, and amount present in the solid materials discharged from the furnace, calculating the volume of gas which must have been produced. The percentage composition of the waste gases is of course required in the application of this method, as well as the chemical composition of the charge. The method can also be applied to the calculation of the heat and power value of the exit gases from blast-furnaces, and examples are given in the original article of all three applications. The method has proved itself reliable when applied to the gas production of three blast-furnaces, and should prove of considerable value in the designing and planning of gas-power installations in connection with large ironworks.

Molybdenum; Determination of ——. J. Darroch and C. A. Meiklejohn. XXIII., page 1176.

Mineral production of the United Kingdom in 1905. [T.R.]

THE following table, showing the quantity and value of the minerals produced in the United Kingdom in 1905, as compared with 1904, is taken from the General Report and Statistics on Mines and Quarries, 1905, Part III., recently issued by the Home Office.

The decrease in the total value of the minerals raised during the year is to be accounted for by a further fall in the average price of coal from 7s. 2·58d. per ton in 1904 to 6s. 11·38d. in 1905. The total output of coal was the highest hitherto recorded. The quantity of coal exported exclusive of coke and patent fuel and of coal shipped for the use of steamers engaged in foreign trade, was 47,476,707 tons, an increase of nearly 1½ million tons on the exports for 1904. Germany received over 7½ million tons, France and Italy each over six million tons, Sweden over three million tons, and Russia, Spain, Denmark, and Egypt each over two million tons. Adding the 2,287,792 tons exported in the form of coke and patent fuel, and the 17,396,146 tons shipped for the use of British and foreign steamers engaged in foreign trade, the total quantity of coal which left the country was 67,160,645 tons. The amount of coal remaining for home consumption was 168,968,291 tons, or 3·91 tons per head of the population. 19,255,555 tons were used in the blast-furnaces for the manufacture of pig iron, as against 17,535,337 tons in the previous year. 33,452,943 tons were used in the manufacture of coke, and 1,109,797 tons in the manufacture of briquettes in 1905. Particulars relating to the manufacture of coke and briquettes are given for the first time, the quantity of coke obtained being 18,037,985 tons, valued at £10,625,799. The number of coke ovens in use during the year was 31,060. The quantity of briquettes produced was 1,219,586 tons, valued at £717,671. The output of iron ore shows an increase of 816,421 tons, and the value an increase of £356,370 on that of 1904. The ore yielded 4,760,187 tons of iron, or nearly one-half of the total quantity of pig iron made in the country. 7,344,786 tons of iron ore were imported during the year, over 78 per cent. of which came from Spain.

* Exclusive of 350 tons of micaceous iron ore, used for paint.

† Exclusive of 443 tons of micaceous iron ore, used for paint.

‡ Value of 141 tons only.

§ These figures differ slightly from those previously given, owing to correction of errors in certain returns, viz.: 1118 tons of slate corrected to 1118 tons of sandstone, and 28 tons of iron ore, which have been added to ochre, umber, &c.

‖ Value not yet ascertained.

Manganese in Mysore, India. Eng. and Min. J., Nov. 3, 1906. [T.R.]

A NEW deposit of manganese which promises to be an important source of supply is being opened up in Mysore State, India. It is situated 20 miles north-west of Shimoga Station on the Southern Mahratta Railway, 340 miles from Mormugoa. The distance from the deposit to the railway is covered partly by ordinary road, but the four miles nearest the mine are in dense jungle, through which a rough road has been cut. The ground is now being surveyed for a branch line from the railway. The deposit was discovered in August, 1905. By the end of 1905 mining was in full swing, and between March and August of the current year 20,000 tons were shipped to the coast and 25,000 tons additional made ready for immediate shipment. On the surface the ore occurs in nodules and boulders cemented together with a form of laterite clay. These vary in size from an inch in diameter to several tons in weight. This deposit extends over an area of several thousand square yards, as far as has yet been ascertained. At one point a well defined lode of high-grade ore has been opened up. The ore is very compact, crystalline, and hard, with a bright metallic fracture, and contains over 55 per cent. of manganese.

Uranium discovery in Canada. Mining World, Nov. 10, 1906. [T.R.]

An important discovery has been made in the Laurentian mountains not far from Labell, Que., and close to the Canadian Pacific Railway, of graphite and uranium. The minerals from which radium is extracted have been found in paying quantities.

ENGLISH PATENTS.

Iron and other metals; Manufacture of ——, and the utilisation of lignite or other fuel therein. H. T. Simpson, known as A. T. Simpson, Bilbao, Spain, and A. E. Bourcond, Gijon, Spain. Eng. Pat. 21,060, Oct. 17, 1905.

The iron ore is first reduced by hot carbon monoxide produced from the lignite, and the reduced metal is then smelted electrically. For this purpose, the ore and flux are fed into a closed blast-furnace, through the tuyères of which carbon monoxide at about 1000° to 1200° C. is blown; the carbon dioxide formed, together with unaltered carbon monoxide passes from the top of the furnace into a pipe leading to a circulating pump. From this the gases pass through a heater to the producer, which contains incandescent coke made from the lignite; here the carbon dioxide is reconverted into twice its volume of carbon monoxide. The gases then traverse a second heater, and afterwards pass again to the furnace. Suitable means are provided for removing the extra volume of carbon monoxide formed during the cycle; the gas so removed may serve to heat the two heaters through which the remaining gas passes. In order to keep the carbon monoxide as pure as possible, lime may be employed instead of limestone as a flux for the ore. The lower part of the blast-furnace forms the crucible or hearth of an electric furnace (preferably of the Kjellin or Gin types); the reduced metal, together with the gangue, drops into this crucible, and is there smelted.
—A. G. L.

Manganese steel rail; Cast ——. W. Brinton, High Bridge, U.S.A. Eng. Pat. 3900, Feb. 16, 1906.

See U.S. Pat. 812,811 of 1906; this J., 1906, 269.—T.F.B.

Steel; Manufacture or treatment of ——. R. A. Hadfield, Sheffield. Eng. Pat. 4107, Feb. 19, 1906.

See U.S. Pat. 834,904 of 1906; following these.—T. F. B.

Iron or steel; Case-hardening of ——. F. Grünewald, Berlin, Germany. Eng. Pat. 12,130, May 24, 1906.

The iron or steel plates to be treated are heated in a muffle furnace from which external air is entirely excluded, and into which air is passed from a carburetter. The quantity of carbon absorbed by the metal can be regulated by using hot or cold air, or by altering the duration of heating. Suitable carburetters are those described by the inventor in Eng. Pats. 12,127, 12,128 and 12,129 of 1906.—A. G. L.

Gold, silver, and other metals; Extraction of —— from metal-bearing matter. J. G. Slater, Toronto, Canada. Eng. Pat. 21,549, Oct. 23, 1905.

The metal-bearing matter—ores, sand, quartz, &c.—is first reduced to an impalpable powder, and treated by the usual amalgamation and cyanide processes. The residue (1 part) is then mixed with potassium nitrate (1 part), and sea salt (½ part), the whole ground together, and put into a crucible or retort, on the bottom of which has been placed one-sixth part of copper. The mixture is then boiled in a hard coke furnace at a temperature of 2000° C. for one hour. The button of copper obtained will then contain the metals from the residue. The furnace used is provided with a close-fitting cover connected to an "accumulator" in which any gaseous metallic sulphides condense and settle.—A. G. L.

Disintegrating, washing, and screening machines [for ores]. C. B. C. Storey, Lancaster. Eng. Pat. 14,418, July 12, 1905.

See Fr. Pat. 367,477 of 1906; following these.—T. F. B.

Ore separators; Centrifugal ——. W. H. Peck, Chicago, Illinois. Eng. Pat. 21,634, Oct. 24, 1905.

Essentially the invention consists in an ore separator in which the size of the passage between the deflector and the containing vessel can be increased or decreased. This lateral movement of the deflector is accomplished without destroying the continuity of the wall of the deflector, by providing the latter with movable sections which collectively form an approximately circular circumferential contour, and giving these sections a flexible watertight covering of rubber and canvas, which covering forms the wall of the deflector. The containing vessel and deflector are revolved at different speeds.—A. G. L.

Ore separators; Centrifugal ——. W. H. Peck, Chicago, Illinois. Eng. Pat. 21,635, Oct. 24, 1905.

The object of this invention is the same as that of the preceding. A differentially rotatable core or deflector is made capable of substantially uniform radial expansion or contraction by constructing it in a number of sections, which can be pushed further from, or nearer towards, the centre, and which are covered by a watertight material forming the outer wall of the deflector.—A. G. L.

Ore concentrators; Centrifugal ——. P. H. Adams, Chicago, Illinois. Eng. Pat. 21,639, Oct. 24, 1905.

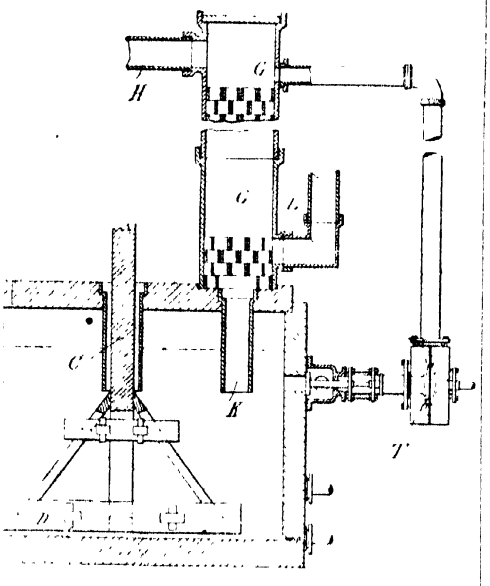
The ore concentrator consists of a rotatable tapering treatment vessel and a rotatable tapering deflector or core. By raising or lowering the latter in the treatment vessel, the channel between the two can be diminished or enlarged. Means are provided by which material can be removed by means of a current of water from a desired portion of the separating apparatus near the discharge end without disturbing the richer material near the feed end. Automatic means are provided to prevent the water from flowing up into the channel beyond a desired distance during the removal; these means open when the deflector is rotating at a low speed and close when it is at a high speed.—A. G. L.

Ore separators; Centrifugal ——. W. H. Peck, Chicago, Illinois. Eng. Pat. 21,650, Oct. 24, 1905.

The invention relates to a brake which lowers the speed of rotation of the treatment vessel of an ore separator during the time that material is to be removed from its surface. The motive power which rotates the vessel being partly discontinued by any suitable means, a friction wheel is brought into contact with the treatment vessel; the consequent revolution of the friction wheel rotates a fly-wheel governor, which is regulated so that as long as the rotation of the vessel exceeds a certain speed, the governor opens a valve admitting water into a hydraulic cylinder, which then applies suitable brakes to the treatment vessel. The whole is regulated so that during the removal of material from the surface of the treatment vessel, the latter should revolve at the (low) speed best suited for this operation.—A. G. L.

Ore separators; Centrifugal ——. P. H. Adams, Chicago, Illinois. Eng. Pat. 21,663, Oct. 24, 1905.

The ore separator consists of a rotatable treatment vessel tapering towards one end, and a rotatable deflector of similar shape, horizontally movable within the treatment vessel so as to enlarge or decrease the channel between the two. Means are provided for feeding material and water into the vessel at a distance from its feed end substantially equal to the distance through which the deflector moves, and means for discharge are placed at a similar distance from the discharge end. The deflector is of sufficient length substantially to cover the points of feed and the discharge openings.—A. G. L.



Ore concentration. Minerals Separation, Ltd., London. From G. A. Chapman, Broken Hill, N.S.W. Eng. Pat. 17,328, Aug. 1, 1906.

The process, consisting in agitating finely-divided ore suspended in acidulated water, described in Eng. Pat. 7803 of 1905 (this J., 1906, 184; also Fr. Pat. 354,960 of 1905; this J., 1905, 1177), is now modified by first introducing the ore, water, and acid into an agitating vessel,

terwards adding the necessary small proportion of oil the like in a second agitating vessel, and finally heating e pulp in a third agitating vessel, in which the acid is actically neutralised.—E. S.

lphide ores; Process and apparatus for the treatment of [complex or ferruginous] ——. H. Baker and A. T. Smith, Weston Point, Cheshire. Eng. Pat. 22,235, Oct. 31, 1905.

NELY-DIVIDED sulphide ores, while being agitated with ter, are treated, indirectly, with chlorine, in the m of ferric chloride preferably, ferric chloride rived from solutions taken from previous workings ntaining ferrous chloride, converted into ferric chloride direct treatment with chlorine. The large tank own in the drawing is constructed of stone, and the essories are of earthenware or the like, except the tator, D, suspended adjustably from the pipe, C, which itator is made of wood, tarred or otherwise protected.

ter and the finely-divided ore are introduced into the r, and the agitator being kept in motion, liquor from revious working in the column or tower, G, receives tream of chlorine through the valved pipe, H, for version of a portion of the ferrous chloride present ferric chloride. The liquor descends the tower ked with earthenware tubes or the like), and flows ugh the pipe, K, into the magma of ore and water. liquor is withdrawn, and forced to the top of the mn, G, by the centrifugal pump, T, and after being n treated with chlorine is returned to the tank through pipe, K, as before. Unabsorbed gases have outlet ugh the pipe, L. Steam is preferably injected. Towards end of the working, sulphur is set free, and floats he surface, whence it may be withdrawn through manhole, M, and is drained and pressed into cakes. n the sulphide ore contains metals precipitable ron or zinc, such as lead, copper, silver, &c., the slurry hlorides prepared as described, is treated with finely- ded sulphide ore, to convert most of the ferric into ous chloride. The solution is then digested with or zinc powder, or scrap, with constant agitation. tals of lead chloride suspended in the liquor are d to thus yield spongy lead, whilst copper also rates from cuprous chloride. The slurry containing e precipitates, drawn off from outlets at different s, so as to keep apart portions containing metals the lighter superincumbent layers with gangue, is filtered, and the metals collected are separated. In one form of apparatus, the reacting tank is caused to revolve on a horizontal axis, and provision is made for the withdrawal of the slurry. Chlorine may be supplied to the ore by the chloride of another metal, such as copper, capable of forming a higher chloride, instead of by ferric chloride.—E. S.

Flux or physic for the treatment of cast iron and other metals. J. Davies, Birmingham. Eng. Pat. 23,783, Nov. 18, 1905.

To the molten cast-iron or other metal is added a flux composed of charcoal, rock salt, limestone, plumbago, sodium carbonate, manganese, and nickel in suitable proportions. The metal obtained can be hardened and tempered like steel.—A. G. L.

Metals; Annealing of ——. D. Bates and G. W. Peard, Huyton, Lancs. Eng. Pat. 324, Jan. 5, 1906.

THE articles are annealed in a non-oxidising atmosphere by placing them on an endless conveyor which passes through an inclined chamber. Part of this chamber is heated in a furnace; the other part, which forms the discharge end, dips into a trough of water or other cooling liquid by which the articles are cooled below their oxidising point before they emerge into the atmosphere. The upper or feed end of the chamber is either open or else closed to such an extent as to admit only of the continuous entry of the articles. Steam or another non-oxidising gas is blown into the chamber, from a pipe entering near the discharge end, in such volume as to flow continuously out at the feed end, which latter may in addition be protected by means of a steam curtain, formed by steam under pressure emerging from a number of suitably placed jets.—A. G. L.

Lead and alloys of lead; Solvent for —— especially suitable for the removal of lead fouling from gun barrels. Kings Norton Metal Co., Ltd., T. A. Bayliss, and H. W. Brownsdon, London, and H. M. Smith, Abbey Wood, Kent. Eng. Pat. 2506, Feb. 1, 1906.

To a solution formed by dissolving 25 grms. of sodium hydroxide in 100 c.c. of water, 10 grms. of ammonium persulphate are added, immediately before applying the solution as a solvent for the deposits in gun barrels, &c. Or, tablets are formed, which may be stored, and dissolved in a solution of alkali hydroxide for application when needed, by mixing ammonium persulphate with from 5 to 20 per cent. of its weight of ammonium carbonate, and compressing in moulds. Other persulphates than that of ammonium, and other oxidising salts than persulphates, such as perborates or hypochlorites, may be employed. (Reference is made to Eng. Pat. 13,297 of 1905; this J., 1906, 378.)—E. S.

Aluminium alloys, and process for producing the same. J. O. O'Brien, Manchester. From A. Chambaud, Paris. Eng. Pat. 9750, April 26, 1906.

THE constituents of the alloy are:—Aluminium, 99·02; iron, 0·31; zinc, 0·01; magnesium, 0·041; and copper, 0·610 per cent. About one-fifth of the aluminium is first melted, the copper is then added, followed by the zinc and iron; the remainder of the aluminium is next added, and after withdrawal from the source of heat, the magnesium is introduced. The alloy is stated to be malleable and ductile, easily welded, and resistant to corrosion by sea-water and air.—E. S.

UNITED STATES PATENTS.

Steel armour-plates; Manufacture or treatment of ——. R. A. Hadfield, Sheffield. U.S. Pat. 834,904, Nov. 6, 1906.

THE castings are cooled slowly in a furnace, cleaned, heated for several days at 900°—1100° C. while in contact with carbonaceous material, allowed to cool gradually in the furnace, reheated to 700°—850° C., and cooled slowly. The castings are then again heated to 700°—850° C., cooled to 640°—690° C., quenched in water, reheated to 570°—640° C., cooled, heated again to

570°—640° C., quenched, and then taper-heated to 700°—770° C. at the face, tapering to 400°—600° C. at the back, and dipped in or sprayed with oil and water.—A. S.

Smelting; Process of ——. W. H. Adams and F. Powell, Portland, Oreg., Assignors to The Ladd Metals Co., Oregon. U.S. Pat. 834,240, Oct. 30, 1906.

The smelting process is carried out by means of gas. The gas is generated from a long horizontal body of fuel in a generator, so arranged that a horizontal zone of incandescence is maintained in it, and through this zone the products of combustion and volatile portions of the fuel must pass (see U.S. Pat. 834,238, page 1139). The gas generated is burned in a suitable flue, which leads to the base of a column of coarse ore, a blast of sufficient pressure to force the heat upward through the column of ore being maintained. Fine ore to be smelted, combined with fresh air, is fed into the flue, and added to the bath of molten ore at the base of the column.—W. C. H.

Metals and ores; Process and apparatus for separating ——. T. Groesbeck, Cincinnati, Ohio. U.S. Pat. 834,722, Oct. 30, 1906.

The apparatus consists of a receptacle mounted on a horizontal axis, and provided with a charging door near the periphery, and a discharge door at one side near the axis. The material containing metals or ores of high specific gravity is introduced into the receptacle, and the latter is slowly rotated one or more complete revolutions, whereby, it is stated, the material of high specific gravity concentrates about the axis of rotation, and is removed through the door provided for that purpose.—A. S.

Furnace; Smelting —. F. L. McGahan, St. Louis, Mo. U.S. Pat. 834,747, Oct. 30, 1906.

The apparatus comprises an ore-smelting chamber communicating with an "inclined inclosure," the latter being divided by a "water-grating" into a roasting chamber and a gas-flue. The roasted ore is discharged from the roasting chamber into the smelting chamber, which is separated from the former by a movable "water-grating." The smelting chamber is heated by a combustion chamber or chambers provided with fuel injectors with steam-pipe connections. The hot products of combustion and unconsumed gases from the ore-roasting and combustion chambers are passed to a carburetter supplied with suitable fuel, thence to superheating pipes surrounding the smelting chamber, and then back to the combustion chamber. Steam is supplied to the superheating pipes.—A. S.

Metals; Apparatus for recovering ——. W. A. Hendryx, Denver, Colo. U.S. Pat. 834,803, Oct. 30, 1906.

The metal-bearing material and solvent solution are circulated and aërated in a tank, and a number of precipitating cells, each composed of a precipitating agent (metallic zinc in a divided form), covered by a filtering medium, are arranged in position to be submerged in the material contained in the tank. The metal-bearing solution is withdrawn from the tank through the precipitating cells, and afterwards returned to the tank.
—A. S.

Molybdenum and its alloys; Process of producing ——. F. M. Becket, Niagara Falls, N.Y., Assignor to Electro-Metallurgical Co., W. Va. U.S. Pat 835,052, Nov. 6, 1906.

For the production of molybdenum, the process consists in smelting a mixture of molybdenum sulphide, carbon, and an oxygen compound of a metal with a relatively high affinity for sulphur, such as lime or other alkali or alkaline-earth compound. If it be desired to obtain alloys, a compound of the metal to be alloyed with the molybdenum is added to the charge.—A. S.

Ore concentration. H. L. Sulman, H. F. Kirkpatrick-Picard, and J. Ballot, London. U.S. Pats. 835,120 and 835,479, Nov. 6, 1906.

See Fr. Pats. 354,960 of 1905, and 363,418 of 1906; this J., 1905, 1177, and 1906, 890.—T. F. B.

Ore concentration. H. L. Sulman, London. U.S. Pat. 835,143, Nov. 6, 1906.

See Eng. Pat. 19,709 of 1905; this J., 1906, 850.—T. F. B.

Fine ores; Method of agglomerating ——. F. E. Bachman, Assignor to Northern Iron Co., Port Henry, N.Y. U.S. Pat. 835,232, Nov. 6, 1906.

Fine ores, flue dust, and the like are mixed with a suitable quantity of coke-breeze or other carbonaceous material, and the mixture is passed through a rotary kiln wherein it is heated, by a flame produced with blast-furnace gas, to a temperature below the fusing point of the ore, but sufficient to effect the combustion of the carbonaceous material, and the fusion of its ash. The fused ash effects the agglomeration of the fine ore.—A. S.

French Patents.

Manganese steel rail. W Brinton. Fr. Pat. 363,400, Feb. 19, 1906.

See U.S. Pat 812,811 of 1906; this J., 1906, 269.—T. F. B.

Smelting [steel, &c.]; Process and furnace for — —. A. Koch. Fr. Pat. 367,470, June 27, 1906. Under Int. Conv., June 27, 1905.

Two fusion chambers are built side by side with air- and oil-heating chambers between them; they are used alternately for preheating the charge and for melting it. The liquid fuel and air enter the working chamber and burn, and the waste gases pass through the preheating chamber and then to the oil heater, where they serve to liquefy and vaporise the oil residues used as fuel, and finally they pass through the air heater to warm the air. A modification is claimed, in which the goods as they pass from the melting to the heating chamber traverse a crucible chamber placed in front, where they serve to superheat the molten metal which collects in the crucible.—W. H. C.

Washing apparatus for all minerals; Mechanical — —. J. Nicholls. First Addition, dated March 5, 1906, to Fr. Pat. 364,771, Feb. 2, 1906 (this J., 1906, 990).

The present addition relates to a form of apparatus for treating, for example, cobalt ores containing finely-divided chromium minerals. It consists of an inclined trough, a short distance above the bottom of which is a metallic plate provided with a slot, or a perforated plate, extending nearly the whole length of the trough. The ore is introduced at the upper end of the trough, as also is a current of water, and a vibratory motion is imparted to the trough. The heavier and more finely divided chromium ore gradually passes to the bottom of the trough, below the plate, whilst the lighter and coarser cobalt ore is carried along above the plate. The two minerals are collected in separate receptacles at the lower end of the trough.—A. S.

Minerals and other substances; Process and apparatus for the treatment of —— by powdering, washing, and sifting. C. B. C. Storey. Fr. Pat. 367,477, June 27, 1906. Under Int. Conv., July 12, 1905.

The apparatus for the disintegration of the minerals, &c., consists essentially of a number of horizontal concentric rotating cylinders. Each cylinder or every second cylinder is provided at one end with a sieve of increasing fineness; in the second case the alternate cylinders serve merely to prolong the path of the mineral, being furnished with an opening at the ends remote from the sieves. The mineral is introduced into the innermost cylinder, together with water, air, or chemicals; as it is crushed, it gradually passes through the sieves to the outer cylinders, a number of residues being finally obtained in the different cylinders. The principle of the invention is that friable particles should be ground and crushed by harder particles of the same size.—A. G. L.

Cupola with fore-hearth heated by regeneration. J. M. Pignarre. Fr. Pat. 367,650, April 21, 1906.

The blast-furnace is provided with an adjacent fore-hearth at its bottom. By closing the top of the blast-furnace

entirely, the products of combustion from it are forced to pass through the fore-hearth on their way to a flue, half-way up the blast-furnace, which leads them to the chimney. The molten metal from the blast furnace can be run into the fore-hearth by means of a channel controlled by a valve. When the fore-hearth is hot enough, the flue leading from it to the chimney can be shut and the top of the blast-furnace opened, so that the latter then works in the normal way. A removable plate underneath the blast-furnace allows the latter to be entirely emptied after each run.—A. G. L.

Furnace for the extraction of zinc and its ores. P. Schmidt und Desgraz, G.m.b.H. Fr. Pat. 367,368, June 23, 1906.

THE claim is for a furnace heated by gas, with a continuous flame. The muffles are arranged along two sides of a heating chamber extending the length of the furnace. Several burners, arranged in pairs, are disposed in the hearth of the heating chamber, each pair communicating with the gas supply by a valve which can be operated by hand from outside the furnace. The air supply passes from a recuperator to a common conduit, wherein it is heated, and whence it passes to the burners through valved openings, which also can be regulated by hand from outside the furnace. It is stated that in this way a uniform degree of heating is attained in all parts of the furnace, and that the temperature can be easily controlled. —A. S.

Ores of iron and manganese, burnt pyrites, blast-furnace dust, and similar products; Process for the agglomeration of ——. F. Heberlein. Fr. Pat. 367,394, June 14, 1906.

THE finely-divided ore or other material is mixed with a suitable combustible, with or without addition of water. The mixture is ignited, and a current of air under pressure is blown through the mass, whereby sufficient heat is produced to cause the mineral to frit, whilst volatile matters are expelled.—A. S.

Copper; Metallurgical and electro-metallurgical process for obtaining pure ——. L. Jumau. Fr. Pat. 367,452, June 26, 1906.

THE process is based on the fact that if a copper salt be heated in a closed vessel under pressure with sulphurous acid, the latter is oxidised to sulphuric acid, and metallic copper is produced. Copper sulphate solution obtained by the usual method is treated with sulphurous acid or a sulphite, and heated in a lead-lined vessel, under pressure, to about 170° C. Metallic copper of 99·9 per cent. purity is, it is stated, thus obtained, and can be converted into bars by fusion or by pressure. If precious metals are present, they can be removed by electrolytically refining the precipitated copper, or they can be precipitated from the copper sulphate solution by a preliminary heating with calcium sulphite under atmospheric pressure.—A. S.

Cobalt and nickel; Process for the extraction and recovery of —— from ores and oxidised mattes. The Metals Extraction Corporation, Ltd. Fr. Pat. 367,717, July 4, 1906.

THE finely-ground ore or roasted matte is heated in an autoclave under steam pressure with a concentrated solution of magnesium chloride. It has been found that practically the whole of the cobalt is converted into chloride and dissolved before the nickel is attacked. After a suitable time the cobalt solution is drawn off, and the process then repeated until the nickel is dissolved. The cobalt and nickel are recovered from the solution by known methods.

In a modification of the process, the powdered ore is mixed with magnesium chloride and water to a paste, which is dried and then heated to about 300° C. The cobalt and nickel chlorides produced are removed by lixiviation with water, and the metals separated from the solution by known methods.—A. S.

Tinning and soldering; Process and powder for ——. F. Plathner and V. Dorn. Fr. Pat. 367,776, July 5, 1906. Under Int. Conv., March 20, 1906.

Two kilos. of powdered tin or lead, or of a mixture of the two metals, are mixed with 1 kilo. of powdered zinc chloride, ammonium chloride, or other deoxidising agent, and 500 c.c. of water, alcohol, or other inert solvent. The mixture is applied to the object to be coated, which is then heated in any usual way until the metal melts and adheres to the object.—A. G. L.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 1106.)

(*A.*)—ELECTRO-CHEMISTRY.

Carbon; Cathodic disintegration of —— in electrolyte of fused sodium chloride. G. J. Kemmerer. Trans. Amer. Electrochem. Soc., 1906, **9**, 117—119.

WHILST graphite is unattacked, and other forms of carbon are fairly durable, when used as anodes in the electrolysis of fused sodium chloride, they are readily attacked when used as cathodes. A quantity of sodium chloride was fused with the aid of a graphite cathode, which was afterwards replaced by a weighed rod of carbon (as used in arc lamps) or graphite, ½ in. square, dipping 1½ in. below the surface of the electrolyte. A current of 27 ampères was employed, the E.M.F. being 24 volts with the graphite and 27 volts with the carbon. After a definite period of time, the rods were withdrawn, well washed, dried at 100° C., and the loss of weight ascertained. In every experiment with the carbon rods, the portion dipping into the electrolyte was completely disintegrated in 1½—2 mins. A graphite rod weighing 29·792 grms. suffered a loss of 0·134 grm. in 10 mins., whilst a carbon rod weighing 39·215 grms. lost 6·735 grms. in 1½ mins.—A. S.

Ozone; Production of ——. C. Harries. Annalen, 1905, **343**, 341—344.

THE ozoniser used by the author consists essentially of a set of 10 Berthelot tubes arranged in parallel. One of the Berthelot tubes is shown in Fig. 1, and a plan of the apparatus is shown in Fig. 2. The tubes are disposed

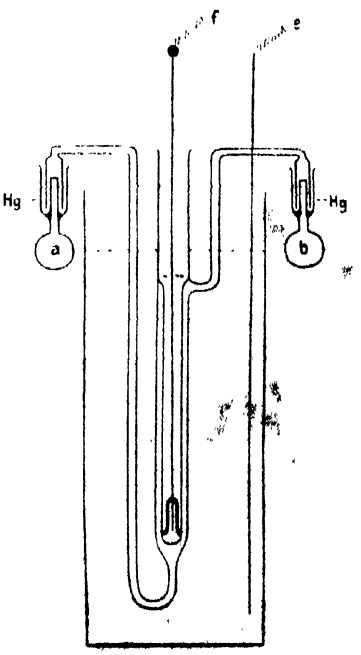


FIG. 1.

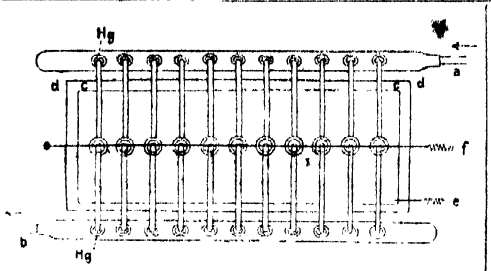

FIG. 2.

in a containing vessel, *c*, of glass, and both tubes and outer vessel are filled with water to a certain level. The whole is placed in a wooden box, *d*. Each tube has an electrode of aluminium wire, and these wires are joined, above the apparatus, by a long wire which forms one pole, *f*, for the current. Another aluminium wire dips into the water in the containing vessel, and forms the other pole, *e*. The ends of the Berthelot tubes dip into mercury seals. The oxygen enters at *a*, and, after ozonisation, leaves at *b*. With a current of about 2 ampères at 110 volts, transformed to about 10,000 volts, and with the oxygen led through at a rate of 5—6 litres in 12 mins., a yield of about 5·6 per cent. of ozone was obtained. It is advantageous to keep the water in the ozoniser cold, and to carefully dry the oxygen.—A. S.

Ozone; Preparation of ——. C. Harries. Ber., 1906, **39**, 3667—3670.

THE author had previously (see preceding abstract) obtained ozonised oxygen containing 5·6 per cent. of ozone. It is now found that by using 10 Berthelot tubes arranged in series instead of in parallel, a gas containing 11·2 per cent. of ozone is produced. The speed of the stream of oxygen is of great importance; with 10 Berthelot tubes arranged as above, and a stream of oxygen passing at the rate of 0·25—0·2 litre per minute, the resulting gas contained as much as 13 per cent. of ozone. This is the greatest amount which has hitherto been observed.—J. C. C.

ENGLISH PATENTS.

Incandescent electric lamp filaments; Manufacture of —— from thorium. British Thomson-Houston Co. From General Electric Co. Eng. Pat. 14,972A, July 20, 1905. II., page 1139.

Electric conductor; Method and means of hermetically sealing a wire or metallic —— or other substance through or into vitreous substance, such as lead, Jena, or quartz glass. C. O. Bastian and G. Calvert. London. Eng. Pat. 21,383, Oct. 20, 1905.

THE method described of hermetically sealing a wire or other suitable electrical conductor through, or into, or on to a hard vitreous substance, such as Jena or quartz glass, consists in utilising the difference between the coefficients of both expansion and contraction of the electrical conductor and of the glass. In order to utilise these physical properties, the conductor is provided at two or more points with heads or enlargements, at a suitable distance apart. These enlargements are arranged, relatively to the glass, in such a way that as the portion of the conductor between them contracts on cooling, they are pressed against the glass to form and maintain an air-tight joint. If, however, the glass and conductor are reheated sufficiently to cause any unsealing of the joint, due to the enlargements not pressing tightly against the glass, the (cubical) expansion of the conductor is so chosen that it still maintains the joint gas-tight by pressing against the glass surrounding it.—W. C. H.

Electrolytic apparatus. E. Hermite, Paris. Eng. Pat. 2465, Jan. 31, 1906.

THIS invention relates to an apparatus for the electrodecomposition of solutions, such as common salt and magnesium chloride. Several pairs of electrodes are connected in series in a single continuous electrolytic tank, the latter being divided by partitions into narrow compartments. The anode consists of a fine platinum wire threaded through holes in a slate slab, and on each side is bound a cathode zinc plate, the two plates being connected by metal bolts. Space is provided, between anode and cathode, for the circulation of the electrolyte, and the zinc plates are provided with shoulders, so that the electrodes may be supported on the walls or partitions of the electrolytic tank. The pairs of electrodes are so spaced that the resistance of the electrolyte between successive pairs is relatively great as compared with the resistance from one member to the other of any one pair. Leakage between successive pairs of electrodes is avoided, and high potentials may be used, without cutting down by interposed resistances or using a number of separate electrolytic tanks in series.—B. N.

Hypochlorite solutions; Manufacture of —— by electrolytic methods. W. P. Digby, London. Eng. Pat. 21,949, Oct. 28, 1905.

THE decomposition products at the anode and cathode are isolated from the main body of the electrolyte, one of the products being conveyed, either as an alkaline solution or as a gas, into a porous cell closely enclosing the electrode of opposite sign, in order to prevent combination of the products of decomposition in the main body of the electrolyte. The combination thus takes place in the compartment, where one of the products is liberated in a nascent condition. The porous cells, enclosing the anode and cathode, may be connected by conduits, and water or an alkaline solution may be supplied to the cathode cells, the resulting solution being led directly to the anode cells, or the gaseous products may be drawn off from the anode compartments, and passed into the cathode compartments. A mercury cathode may be employed, and the resulting amalgam washed with water in a separate compartment, the alkaline solution formed being led into the anode porous cells. The electrodes may, if necessary, be cooled by expanding ammonia or other compressed gas within them. The porous cells, surrounding the anode and cathode, consist of an asbestos sheet, bound between ebonite plates, the outer one being provided with vertical and the inner with horizontal slots.—B. N.

Fusion of materials by electricity; Effecting ——. G. F. Brindley, Niagara Falls. Eng. Pat. 11,675, May 18, 1906.

SEE Fr. Pat. 366,523 of 1906; this J., 1906, 1053.—T. F. B.

FRENCH PATENTS.

Electrolytic process. J. Tanne and E. Papenbruch. Fr. Pat. 367,440, June 26, 1906. Under Int. Conv., June 29, 1905.

THE materials to be submitted to electrolysis, either in the form of gases or finely-pulverised solids, are passed through the hollow electrodes under pressure, the orifices of the electrodes being opposite to each other in a reaction chamber, so that the materials differently charged with electricity are brought into mutual collision. The reaction chamber is connected to a cooling chamber, both being cooled by a continuous flow of cold water.—B. N.

Diaphragm; Electrolytic ——. I. L. Roberts, United States. Fr. Pat. 367,835, July 6, 1906.

THE invention relates to an electrolytic diaphragm, comprising a rigid element of porous material covered by a layer of non-porous material, the latter being maintained in position on the rigid element by means of linen cloth. The latter may also be covered by an open-work metallic support.—B. N.

GERMAN PATENT.

Mercury light; Apparatus for the illumination of liquids by —— for the purpose of producing chemical reaction. Schott und Gen. Ger. Pat. 172,681, March 3, 1905.

THE mercury lamp is placed in a glass tube, and the latter

immersed in the liquid which is to be exposed to the light from the lamp. This device is to avoid the necessity of constructing a special form of lamp which would be required if the lamp were placed directly in contact with the liquid, owing to the rapid withdrawal of heat by the latter from the lamp. If it be desired to work continuously, the tube containing the lamp is surrounded by several concentric tubes, opening alternately at top and bottom. The liquid is fed in at the top between the outermost tube and the containing vessel, flows through the annular spaces between the tubes, and is withdrawn at the bottom from the smallest tube.—A. S.

(*B.*)—ELECTRO-METALLURGY.

Electro-deposits [Iron]; Structure of ——. C. F. Burgess and O. P. Watts. Trans. Amer. Electrochem. Soc., 1906, **9**, 229—237.

The authors describe, and show micro-photographs of, some peculiar variations in the physical structure of electro-deposited iron. It is stated that by electrolysing a solution of ferrous sulphate and ammonium chloride at 20°–30° C. with a current density of about 10 ampères per square foot, the electrolyte being circulated through the series of electrolytic tanks by means of a centrifugal pump, and care being taken to exclude dissolved gases from the solution, it is possible to obtain satisfactory deposits of iron of a thickness of at least 1 in., with almost the same ease and rapidity as is the case with copper.—A. S.

Copper ore; Electrolytic treatment of —— at Miedzianka, Russian Poland. W. Stoeger. Oesterr. Z. Berg. u. Hüttenwesen, 1906, **54**, 387—391. Electrochem. and Metall. Ind., 1906, **4**, 366.

The ore (chiefly copper glance, but occasionally containing azurite and malachite) is crushed, formed into briquettes with 5 per cent. of moist loam, and roasted in such a manner as to obtain a mixture of copper sulphate and copper oxide. This is lixiviated with dilute sulphuric acid, and the copper recovered from the solution by electrolysis. Sheet-lead anodes wrapped in a textile fabric are employed, with a current of 1000 ampères, corresponding to 1 ampère per sq. dm. of cathode surface, at 2·5 volts per vat. 1·1 grm. of copper is deposited per ampère-hour. It is stated that the deposited copper is purer than electrolytic copper from refineries. The sulphuric acid produced during electrolysis is used for treating fresh quantities of roasted ore.—A. S.

United States Patents.

Ores [zinc-lead]; Process of treating ——. F. T. Snyder, Oak Park, Ill. U.S. Pat. 834,644, Oct. 30, 1906.

Ores containing metallic constituents reducible at different temperatures are mixed with carbon and slag-forming materials, and introduced, in absence of air, at the deeper end of a bath of molten slag. An electric current is passed through the slag between the deeper and shallower ends, whereby a temperature is produced progressively increasing in intensity towards the shallower end of the slag-bath, and sufficient to reduce in succession the different constituents of the ore. The unreduced ore is gradually moved forward until it reaches the shallow end of the bath, where the heat is sufficient to volatilise the metal last reduced, and completely expel it from the molten slag. The metal first reduced is withdrawn from below the deeper portion of the slag-bath. The process is especially suitable for the treatment of zinc-lead ores, the zinc being volatilised at the shallow end of the bath, and subsequently recovered by condensation, whilst molten lead is withdrawn from the deep end of the bath.—A. S.

Metals; Metallurgical process for the extraction of —— from their ores, and the conversion of iron into steel. G. H. Benjamin, New York. U.S. Pat. 834,656, Oct. 30, 1906.

The ore is mixed with a flux, and subjected to a gradually increasing temperature, and to the action of reducing gases. The partially reduced ore is then caused to move by gravity into a zone of high temperature, wherein it is subjected to the action of successive electric arcs, in the presence of a carbon body which will combine with or react upon it under the influence of the electric arcs. The resulting metal is separated by gravity from accompanying substances, and is subjected to the action of an oxidising atmosphere and of air-blasts. The gases generated from the charge by the action of the electric arc are used for reducing the ore in the first stage of the process.—A. S.

Gold and silver; Means for [electrolytically] precipitating ——. J. Snodgrass, Johannesburg, Transvaal. U.S. Pat. 835,329, Nov. 6, 1906.

The apparatus consists of a receptacle in which cathodes and anodes are disposed alternately. The cathodes each consist of a metallic frame, on both sides of which are secured metallic screens of fine mesh, the whole being covered with a fabric provided with a conductive coating. They rest on a metal plate, contained in the receptacle, by which they are placed in electrical connection. The anodes are disposed in frames of non-conductive material, in the sides of which are slots or holes by means of which the solution takes a sinuous course through the receptacle without passing through the anodes.—A. S.

French Patent.

Ores; Treatment of —— by electrolysis N. H. M. Dekker. Fr. Pat. 367,495, June 28, 1906.

The electrodes are arranged alternately in the electrolytic cell, one electrode being formed of a simple carbon or metallic plate, and the other of a flat vessel, of plaited wood, lined with a fabric containing the material to be treated. The material is divided into two parts by a carbon or metallic plate, which is bound to one of the electric terminals.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 1106.)

Lipase; Action of ——. A. E. Taylor. J. of Biol. Chem., 1906, **2**, 87—104. Chem. Centr., 1906, **2**, 1344—1345.

The lipase was prepared from fresh, ripe castor beans by removing the husks, pounding the kernels, and exhausting the latter with anhydrous ether. The ferment is insoluble in ether, but completely soluble in ether containing dissolved fats. If it be mixed with water and ether, a portion is taken up by the water, but none by the ether; the greater part, however, remains as an intermediate layer. If, now, an ester soluble in ether but not in water be added, the lipase passes into the ether. If, on the other hand, an ester soluble in both ether and water be introduced, the lipase passes into both the ether and the water, and into the latter medium in greater quantity. Ground castor beans contain, besides lipase, amylase, invertase, maltase, and an endotrypain, but no peroxydase. Several protein substances—globulin, albumin, nucleoalbumin, and a glycoprotein—are also present. The greater the degree of purity of the lipase, the less stable it is, as the protein substances serve to protect it from the action of the endotrypain. If turbid aqueous suspensions of lipase be repeatedly filtered through paper, the ferment is retained completely by the paper. In the dry condition the ferment is not injured by heating above 100° C., but is decomposed by heating the aqueous suspension, more rapidly in presence of alkali than when the water is acid. In presence of fats, the ferment is more resistant against the action of heat. In experiments on the hydrolysis of triacetin, it was found that the reverse reaction—the synthesis of triacetin—takes place, but only with very low velocity. On hydrolysing solutions of triacetin of different concentration, by means of sulphuric acid and lipase respectively, till equilibrium was established, the results obtained in the two sets of experiments agreed fairly well (see table).

indicating that the ferment acts as a true catalyser, and does not cause a displacement of the equilibrium.

Concentration of triacetin solution, per cent.	0·5	1·0	2·0
Percentage of ester decomposed by—			
(1) Sulphuric acid	88	82	78
(2) Lipase	86	79	70

Experiments on the hydrolysis of triolein showed that the amount of hydrolysis is a linear function of the time, and the degree of acceleration of the hydrolysis is directly proportional to the amount of ferment present. It is stated that dry lipase from castor seeds is capable of effecting the synthesis of all higher fats from glycerol and fatty acids. The author has also succeeded in synthesising triolein from anhydrous glycerol and oleic acid by means of pancreas powder, but failed in similar attempts with palmitic and stearic acids. (See also this J., 1905, 977, 1242; 1906, 994, 1106.)—A. S.

Cod-liver oil; Separation of the fatty acids of ——. H. Bull. Ber. 1906, **39**, 3570—3576.

Fractional distillation of the fatty acids in a current of superheated steam having proved an ineffectual means of separation, the author tried distillation *in vacuo* of the methyl esters, which have a considerably lower boiling point than the fatty acids. It was found that about 80 per cent. of the fatty acid esters passed over below 240° C. at a pressure of 10 mm. Two kilos. of Lofoden cod-liver oil, almost devoid of free fatty acids, were converted into methyl esters of the fatty acids (yield 1960 grms.), and these were fractionated three times in a special vacuum distillation apparatus, the first time at intervals of about 10° C., and subsequently at smaller intervals. The three main fractions thus obtained boiled at 186° C., 206° C., and 224° C. respectively, and there were also considerable fractions boiling at 161·5 to 165° C. and 242° C. respectively. The fraction boiling at 161·5° to 165° C. was partially crystalline at the ordinary temperature, and when recrystallised from alcohol chilled with ice yielded the methyl ester of myristic acid melting at 19° C. The fraction 185° to 186° C., recrystallised from alcohol at about —15° C., gave considerable quantities of the methyl ester of palmitic acid melting at 29·5° C.

New acid of formula $C_{16}H_{30}O_2$:—This was separated from the alcoholic solution from which the palmitic acid ester had been crystallised. The fatty acids in this solution were first converted into barium salts and recrystallised from ether. The residual palmitic acid was then separated in the form of a lead salt insoluble in ether, and a final purification of the new acid effected by converting it into the zinc salt and treating the latter with hot ether. The portion that separated on cooling the solvent yielded a fatty acid melting at —1° C., and having a neutralisation value of 219 and an iodine value of 91·5. On oxidation with alkaline permanganate solution it yielded a dihydroxypalmitic acid crystallising from alcohol in flat plates (m. pt. 125° C.). This fatty acid is present to the extent of about 6 per cent. in cod-liver oil, and is also a constituent of herring and whale oils. It is not identical with the fatty acid of the same formula found by Ljubarsky (this J. 1898, 358) in seal oil, since the dihydroxy acid from the latter melted at 115° C. The fraction distilling at 205°—206° C. contained the methyl esters of stearic acid (in small proportion) and oleic acid.

Gadolinic acid:—The fraction 223° to 225° C. contained a new acid melting at 24·5° C., and having a composition corresponding to the formula $C_{20}H_{38}O_2$, a neutralisation value of 180·5, and iodine value of 80·3. It occurs in considerable quantity in cod-liver oil (whence its suggested name), and is also present in herring and whale oils. In the author's opinion Scharling's doeglic acid (Lewkowitsch, *Oils and Fats*, p. 110) must have consisted of a mixture of gadolinic and oleic acids. When oxidised with alkaline permanganate solution the new acid yielded a dihydroxy acid (which the author termed *dihydroxygadinic acid*), crystallising from alcohol in brilliant white crystals (m. pt. 127·5°—128° C.). From the distillation curve the author concluded that Heyerdahl's jecoleic acid (Lewkowitsch, *loc. cit.*) could not have been present in any considerable quantity, and that Heyerdahl's dihydroxy derivative was probably a mixture of the hydroxy derivatives of oleic and gadolinic acids. The fraction boiling at 239°—240° C. contained a fatty acid melting at 34° C., and having a neutralisation value of 165·4. It was identified as erucic acid, $C_{22}H_{42}O_2$. The lead salt, like that of gadolinic acid, was only slightly soluble in ether, and the potassium salt was nearly insoluble in cold alcohol. (See also this J., 1906, 818.)—C. A. M.

Oleic acid; Remarks on Molinari and Soncini's paper on the constitution of ——. C. Harries. Ber., 1906, **39**, 3728—3732. (See this J., 1906, 1055).

In reply to criticisms of Molinari and Soncini the author asserts that his critics must have failed to observe the formation of a perozonide, and only obtained the normal ozonide. He points out that their own analytical figures indicate that they were dealing with a mixture of the two ozonides, since the amounts of carbon found were half way between those calculated for the two compounds. Similar results have been obtained by himself, when sufficient care had not been given to the purification of the normal ozonide. In the author's opinion the following equation represents the decomposition of the ozonides by water:—

$$CH_3(CH_2)_7.CH \overset{O}{\underset{O}{<}} CH.(CH_2)_7CO_2H + H_2O =$$

$$H_2O_2 + CH_3(CH_2)_7.CHO + OCH(CH_2)_7.COOH$$

He further asserts that Molinari and Soncini overlooked the facts that hydrogen peroxide was formed on heating the ozonide with water; that the decomposition by water gave rise to no evolution of gas, which, however, was given off when sodium hydroxide solution was used, the hydrogen peroxide being then destroyed; and that by the action of hot water on the ozonide, aldehydes were formed in addition to acids. As regards the constitution of oleic acid, the position of the double bond was established long ago, *e.g.*, by the work of Baruch.—C. A. M.

Oleic acid ozonides; Decomposition products of ——. C. Harries and H. O. Türk. Ber., 1906, **39**, 3732—3737.

Oleic acid perozonide.—On heating 15 grms. of the heavy oil (this J., 1906, 1055) with 60 grms. of water for 30 minutes on the water-bath, decomposition took place, and the water gave a strong reaction of hydrogen peroxide. The resulting supernatant oil, which solidified on cooling, was dissolved in ether, and shaken with sodium bicarbonate solution, which separated it into two fractions. The portion taken up by the alkali solution consisted of the whole of the azelaic acid and the bulk of the semi-aldehyde of azelaic acid, whilst the part remaining dissolved in the ether consisted of pelargonic acid, nonylic aldehyde and the remainder of the semi-aldehyde of azelaic acid. These fractions were separated further by distillation under a pressure of 17 mm., and the products purified. The total yield amounted to 14·3 grms., and consisted of 2·0 grms. of nonylic aldehyde (b. pt. 80°—105° C. under a pressure of 17 mm.); 4·2 grms. of pelargonic acid (b. pt. 120°—150° C.); 3·7 grms. of distillation residue; and 4·4 grms. of azelaic acid and its semi-aldehyde.

Semi-aldehyde of azelaic acid.—This was insoluble in water, and solidified, on cooling, to a solid white mass, which began to melt at 57° C., and was completely fluid at 63° C. When heated it had a pleasant penetrating aldehydic odour recalling that of roses. It gave the usual reactions of aldehydes and formed a semicarbazone (m. pt. 164° C.). It was extremely unstable, and was readily attacked when heated with dilute mineral acids, being converted into a dark oil insoluble in hot petroleum spirit. The aldehyde itself was readily soluble in ethyl acetate and benzene, but was insoluble in cold petroleum spirit. When dried on a porous tile *in vacuo* its elementary composition corresponded with the formula $CHO(CH_2)_7COOH$. It darkened at about 140° C. and decomposed with evolution of gas

at 180° C. It formed a series of metallic salts, of which the sodium salt resembled soap and was only soluble in a large proportion of water, whilst the ammonium salt was readily soluble, the silver salt soluble with difficulty, and the calcium salt insoluble. In the authors' opinion the acid, $C_{18}H_{32}O_3$, found by Molinari and Soncini (this J., *loc. cit.*) among the decomposition products of oleic acid ozonide was a polymerisation derivative of this aldehydo-acid.

Normal oleic acid ozonide when decomposed by water in the same way as the perozonide gave the following yields from 16 grms. of the original substance:—Nonylic aldehyde, 2·8; pelargonic acid, 5·0; distillation residue, 4·2; and azelaic acids (m. pt. 80° C.), 3·5 grms. Total, 15·5 grms. The mixed azelaic acids were found to contain 3·5 grms. of the aldehydo-acid. The yield of this was reduced when the decomposition of the ozonide by water was continued for too long a time.—C. A. M.

Ozone; Gravimetric determination of ——, *and ozone numbers of oils.* P. Fenaroli. Gaz. chim. ital., 1906, **36**, [2], 292—298.

The author has obtained good results in numerous experiments with oleic acid and linseed oil for the determination of ozone by the method recommended by Molinari and Soncini (this J., 1906, 1055). The oil is contained in a 5-bulb apparatus as used in combustions, and the gas containing ozone is passed through at the rate of about 180 bubbles per minute; the temperature is maintained between 10° and 40° C. A calcium-chloride tube must be joined on to the absorption-bulbs, as even a carefully-dried oil will still give up a small quantity of moisture during the test. The increase of weight of the oil corresponds exactly to the addition of 1 mol. of ozone (O_3) for each double linking in the molecule of the fatty compound.

The ozone-numbers of some oils are given in the following table:—

	Iodine value.	Ozone number.	
		Calculated from iodine value.	Found.
Olive oil ..	83·8	15·9	15·8, 16·3
Maize oil ..	114·1	21·6	22·1, 21·1
Linseed oil .	176·8	33·5	33·4, 34·6
Castor oil .	86·4	16·3	16·3, 16·1

—A. S.

Cocoanut oil in butter fat; Determination of ——. F. W. Harris. Analyst, 1906, **31**, 353—360.

The utility and reliability of the different methods proposed for the detection and determination of cocoanut oil in butter are dealt with in this paper. Juckenack and Pasternack's line of reasoning (this J., 1904, 339), was found to be useless for indicating, with any degree of certainty, the presence of less than 15 per cent. of cocoanut oil. Methods based on the precipitation of certain of the fatty acids as silver salts (this J., 1905, 1025; 1906, 324) also gave unsatisfactory results, but the Polenske process (this J., 1904, 387) was found to be of considerable value in detecting this class of adulteration. The exact conditions of the method must, however, be adhered to, and particular attention paid to the condition of the pumice-stone added to the distillation flask. The most concordant figures are obtained by the addition of 0·1 grm. of finely-powdered pumice-stone, an equal weight in the form of small pieces giving lower results. Provided that a reliable basis of comparison has been obtained by the analysis of a large number of samples having varying Reichert-Meissl values, it is quite possible to detect the presence of 10 per cent. of cocoanut oil in butter, by the Polenske process; the admixture of 15 per cent. can not only be detected, but determined fairly accurately. If the proportion of cocoanut oil indicated be relatively small, confirmation by Bömer's phytosteryl acetate test (this J., 1902, 192) is essential, but it must be remembered that this test shows the presence of all, or any, vegetable oil, and not that of cocoanut oil alone.—W. P. S.

"Inoy" kernels [Poga oleosa]; Fixed oil from ——. Imp. Inst., 1906, **4**, 201.

"Inoy" kernels from the seeds of *Poga oleosa* exported from West Africa, yielded 60·8 per cent. of oil when extracted with light petroleum spirit. The oil was pale yellow, with an unpleasant taste and peculiar odour; it does not solidify or deposit on keeping. Sp. gr. at 15° C., 0·896; saponification value, 184·49; iodine value, 89·75; Hehner value, 93·00; Reichert-Meissl value, 1·45; acid value, 5·2 to 17·8; titer test (solidifying point of fatty acids), 22° C. The marc after extraction of oil gave 41·51 per cent. of proteids, 1·32 per cent. of reducing sugars, 2·5 per cent. of sucrose, 36·92 per cent. of other carbohydrates, 9·00 per cent. of crude fibre, and 8·75 per cent. of ash. The ash contained 49·1 per cent. of phosphoric anhydride present as phosphates. In general characters the oil approximates to cottonseed oil, but has a lower titer number, which renders it less valuable for soap-making.—J. O. B.

Olive leaves; New investigations of ——. F. Canzoneri. Gaz. chim. ital., 1906, **36** [2], 372—376.

The author has continued his study of olive leaves (Gaz. chim. ital., **27** [2], 1). On extracting dry olive leaves for several days with 95 per cent. alcohol, and allowing the solution to cool, small quantities of crystals were obtained, consisting apparently of two wax-like substances, melting at 85°—100° and 69°—70° C. respectively, and exhibiting different degrees of solubility in boiling alcohol. From the alcoholic solution there were isolated: (1) A white compound, $C_{25}H_{44}O_3$ or $C_{24}H_{42}O_3$, melting at 297°—298°C. with decomposition, soluble in ether, and insoluble in petroleum ether; (2) a white, crystalline, resin-like substance, m. pt. 253°—255°C., probably identical with the substance isolated by Peano (this J., 1903, 35) from the epicarp of olives; (3) a compound, crystallising in tetrahedra, m. pt. about 236° C.; (4) a crystalline acid, m. pt. 165°, insoluble in ether; (5) a compound, m. pt. 180° when crystallised from acetic acid, and 200°—235° after recrystallising from alcohol; (6) an acid of dough-like consistence, turning brown when exposed to the air; and (7) mannitol and gallic and tannic acids.—A. S.

Fatty substances; "Alcoholysis" of ——. A. Haller. Compt. rend., 1906, **143**, 657—661.

The author finds that different fats and oils react with very varying degrees of facility on methyl alcohol containing 1—2 per cent. of hydrochloric acid, to form glycerol and the methyl esters of the acids present. In the process, 100 grms. of the fat (freed from moisture) are boiled under a reflux condenser with 200 c.c. of the acidified methyl alcohol till the solution becomes homogeneous, and the liquid is then poured into water or brine, which dissolves the glycerol and excess of alcohol, whilst the esters rise to the top and can be separated. Should the whole mass form an emulsion, it is treated with ether, and the ethereal solution of esters treated with sodium carbonate, dried, and the ether distilled off. The esters are then separated by fractional distillation, at the ordinary or at reduced pressure according to circumstances. Volatile fatty esters are thus easily separated from methyl oleate; but the separation of the latter from palmitate or stearate can only be effected by drainage on a porous tile at 0° C., extracting the liquid from the tile by ether, distilling off the ether, and repeating the process as long as any solid ester is obtained. The process promises to be of use as a method of analysis.—J. T. D.

Carbon tetrachloride; Action of —— on cast iron. R. Bolis. Chem.-Zeit., 1906, **30**, 1117—1118.

The author finds that perfectly dry carbon tetrachloride may be boiled in cast-iron vessels, and will exert very slight action on them; moreover, the metal seems to become covered with a protective coating, so that the action becomes slighter in time, and ultimately ceases. If moisture be present, however, the iron is very sensibly attacked, and the rate of attack increases with the proportion of moisture. In this case, too, the last of successive boilings with carbon tetrachloride shows as strong an

attack as the first. When bones are boiled in cast-iron vessels with carbon tetrachloride to extract the fat, there is always some corrosion of the vessel, which is less with fresh and well-dried bones than with older and moister bones. Under ordinary working conditions this attack may be very serious in amount.—J. T. D.

Maize oil exports from the United States. [T.R.]

THE following figures have been compiled from the "Statistical Abstract of the United States," published by the Bureau of Statistics :—

Year.	Galls.	Value. $
1898	2,646,560	575,646
1899	2,360,623	565,293
1900	4,383,926	1,351,867
1901	4,808,545	1,831,980
1902	4,266,398	1,769,370
1903	3,778,035	1,467,493
1904	3,222,875	998,613
1905	3,108,917	890,937

Cotton-seed pitch; U.S. Customs Decision. Oil, Paint, and Drug Rep., Oct. 22, 1906. [T.R.]

ON Oct. 21, the Board of General Appraisers held that cotton-seed pitch used in connection with insulating cables for electrical purposes must pay duty at the rate of 20 per cent. The importing firm made several claims for exemption from duty and two claims for assessment at the rate of 10 per cent. The Board held that assessment as a non-enumerated manufactured article will stand.

Soap; U.S. Census of ——. Oil, Paint, and Drug Rep., Oct. 29, 1906. [T.R.]

IN 1900 soap and candles were shown as one industry without details and segregation is impracticable. The total cost of materials in 1900 was $33,143,230 and the value of the products $53,231,017. In 1905 the cost of materials used in the manufacture of soap and candles was $46,536,823 and the value of the products $72,164,062. The following table shows the materials used and the value of products for soap only in 1905 :—

Materials used, total cost	$43,625,608
Tallow, grease, and other fats—	
Pounds	475,618,277
Cost	$19,723,311
Cocoanut and palm-kernel oil—	
Gallons	6,833,132
Cost	$2,692,034
Cotton-seed oil—Galls.	13,276,006
Palm oil—Galls.	449,490
Olive oil—Galls.	602,909
Castor oil—Galls.	79,707

FRENCH PATENTS.

Fatty acids; Production of mono-iodo [and mono-bromo] substitution products from higher ——. Farbenfabr. vorm. F. Bayer und Co. First Addition, dated June 21, 1906, to Fr. Pat. 362,370, Jan. 12, 1906. XX., page 1173.

Lubrication; Product suitable for ——. The Emery Pneumatic Lubricator Co. Fr. Pat. 367,320, June 21, 1906.

THE product consists of a mixture of soap or other saponaceous material, graphite, fluid extract of red elm bark (say, 2 parts of each), common salt or a suitable saline compound (1 part), to prevent solidification under the influence of compressed air, and water (4 parts). These ingredients are heated together to boiling point, well stirred until the mass becomes plastic, and then moulded into a convenient shape and wrapped in metal foil, or other impermeable material.—C. S.

Finishing soap [for textiles and paper]; Manufacture of a ——. E. Agostini. Fr. Pat. 361,772, Sept. 16, 1905.

INSOLUBLE soaps such as those of lime, alumina, zinc, &c., are mixed at a high temperature with fatty bodies or hydrocarbons so as to form a homogeneous mass. Weighting materials such as talc, kaolin, &c., can be added to this material. The insoluble soaps may be previously prepared or may be obtained in the fatty mixture by double decomposition between a fatty acid and a metallic hydroxide such as aluminium hydroxide. This material when applied to fabrics or paper yields a finish which is highly insoluble and also resistant to mechanical treatment. —A. B. S.

Candles or other illuminating bodies for nightlights, lamps, or other applications; Process for making —— by means of petroleum or other mineral oils. V. J. Kuess. Fr. Pat. 367,448, June 26, 1906. III., page 1141.

Petroleum or other mineral oils; Process of solidifying ——, and transforming them into a solid hydrocarbon soap. V. J. Kuess. Fr. Pat. 367,449, June 26, 1906. III., page 1141.

* Products consumed in establishments where produced were :—Turkey Red oil, 1,149,846 galls.; tallow, 10,613,271 lb.; cotton-seed oil, 920,410 galls.; causticlye, 30° B., 9,568,532 galls.; sodium silicate, 1,597,886 lb.; glycerin, 3,423,299 lb.; framed soap, 114,452,424 lb.

† In addition, soap products to the value of $1,487,113 were made in establishments engaged primarily in the manufacture of other products.

Glycerins of every description, including spent soap lyes and distillery by-products (vinasses); Process and apparatus for the purification of crude ——. L. Rivière. Fr. Pat. 367,752, July 4, 1906. Under Int. Conv., July 6, 1905.

Salts of sodium and potassium in the crude glycerin are precipitated by means of hydrofluosilicic acid, which is subsequently recovered from the fluosilicates. The free hydrochloric acid in the filtrate, resulting from the decomposition of the sodium chloride, is separated either by distillation with steam, and then saturated with lime; or it is converted into an ester by treatment with alcohol before distillation; or is precipitated as lead chloride by means of lead fluosilicate. The precipitated sodium and potassium fluosilicates may be converted into carbonates by treatment with sufficient lime to form the corresponding silicates and calcium fluoride, after which the silicates are decomposed by means of carbon dioxide and the resulting carbonates separated from the precipitated silica. The latter is dissolved in hydrofluoric acid to form hydrofluosilicic acid, or is converted into lead fluosilicate. All these different operations are carried out in autoclaves to which, when required, condensers and absorption vessels are attached.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(*Continued from page* 1107.)

(*A.*)—PIGMENTS, PAINTS.

English Patents.

Paint; Manufacture of ——. M. F. L. Colignon, Monte Carlo. Eng. Pat. 22,252, Oct. 31, 1905. Under Int. Conv., Nov. 26, 1904.

See Fr. Pat. 348,277 of 1904; this J., 1905, 506. Reference is directed under Section 1, Subsection 2, of the Patents Act, 1902, to Eng. Pats. 3623 of 1876 and 4415 of 1885. —T. F. B.

Basic lead salts [Pigments] insoluble in water; Process of producing ——. J. Kronen, Mulheim-on-the-Rhine, Germany. Eng. Pat. 19,732, Sept. 4, 1906.

The normal lead salt, insoluble in water, is made into a paste form, and then mixed with the calculated quantity of lead oxide or lead ochre.—B. N.

French Patent.

Luminosity; Method of imparting permanent —— to substances. [Luminous paint]. P. L. Despax. Fr. Pat. 367,309. June 20, 1906.

The object is treated with phosphorescent calcium sulphide incorporated with a special colourless varnish (dammar resin, wax and oil of turpentine) which is stated to preserve the luminosity by protecting the sulphide from the action of the air.—C. A. M.

(*B.*)—RESINS, VARNISHES.

Turpentine and rosin; U.S. Census of ——. Oil, Paint, and Drug Rep. [T.R.]

In 1905 there were 1287 establishments engaged in the production of turpentine and rosin, the aggregate output being valued at $23,927,034. In 1900 there were 1503 establishments, but the output was only $20,344,888. Following is a statement of the products by kind, quantity, and value:—

	1905.	1900.
Products, total value	*$23,917,024	$20,344,888
Turpentine—		
Gallons	30,687,051	38,488,170
Value.....	$15,170,499	$14,960,235
Rosin—		
Barrels	†3,508,347	‡2,563,087
Value.....	$8,725,619	$5,129,268
All other products	$40,906	$255,385

* In addition, turpentine and rosin to the value of $26,750 were produced by establishments primarily engaged in the manufacture of other products.
† Barrels of 280 lb.
‡ Including some barrels of 500 lb.

English Patent.

Pitch oils [turpentines] and other ethereal oils obtained by destructive distillation of resinous substances; Purifying ——. A. Hesse, Wilmersdorf, Germany. Eng. Pat. 7934, April 2, 1906.

The malodorous constituents of oils obtained by the destructive distillation of resinous substances are stated to be completely and economically removed by treatment with an alkali metal or an alkaline-earth metal previous to distillation; a preliminary purification with alkali hydroxide or lime may be employed in addition. One thousand kilos. of Russian oil of turpentine are stirred with 3 kilos. of metallic sodium, and the oil is distilled under atmospheric pressure; if necessary, the distillate or any fraction of it may be again treated with sodium. —T. F. B.

United States Patents.

Turpentine; Apparatus for distilling ——. J. G. Saunders, Lake Park, Ga. U.S. Pat. 834,759, Oct. 30, 1906.

The worm of the still discharges into a closed receiver, provided near the top with an outlet for the turpentine, and with a cold-water inlet and outlet at lower levels, the water being admitted from an elevated tank, whilst the water-outlet pipe is bent upward above its connection with the receiver, in order to maintain the level of water therein, and is fitted with a tap for regulating the outflow. —C. S.

Turpentine; Method of distilling ——. J. T. Denny, Cromartie, N.C. U.S. Pat. 834,875, Oct. 30, 1906.

Wood, placed in a holder, is enclosed in a still, and subjected to non-destructive distillation, after which it is taken out of the still, and the holder, and subjected to destructive distillation in a retort, in the ordinary way. —C. S.

(*C.*)—INDIA-RUBBER, &c.

English Patent.

Fibrous agglomerates; Manufacture of [vulcanised] ——. C. A. C. de Caudemberg, Nice, France. Eng. Pat. 9710, April 25, 1906. Under Int. Conv., May 10, 1905.

See Fr. Pat. 354,801 of 1905; this J., 1905, 1118.—T.F.B.

United States Patents.

Rubber; Process of recovering —— from rubber waste. W. A. Koeneman, Chicago, Ill. U.S. Pat. 834,623, Oct. 30, 1906.

The finely-divided waste material is mixed with a "suitable proportion" of a miscible fixed hydrocarbon, such as tar, pitch, resin, or balsam, and boiled in a solution of a mineral acid containing a halogen salt of an alkali metal. The acid and dissolved matter are then separated, and the rubber is boiled in a solution of a salt of an alkali metal, washed, and dried.—C. S.

Gum; Rubber-like ——. R. F. Spencer, Denver, Col., Assignor to the Western Parent Crude Rubber Co., Santa Fé, N. Mex. U.S. Pat. 834,769, Oct. 30, 1906.

The gummy particles in the plant *Picradenia floribunda utilis* are separated from the fibrous portions, and agglomerated, being then converted into a plastic, rubber-like waterproof mass by dissolving them in a light hydrocarbon, such as gasolene.—C. S.

French Patents.

Rubber and rubber waste; Treatment of ——. W. A. Köneman. Fr. Pat. 368,144, June 2, 1906.

See U.S. Pat. 834,623 of 1906; preceding these.—T.F.B.

Compound (Rubber substitute) formed of the gums of certain Sapotaceæ, and method of producing same. M. M. Dessau. Fr. Pat. 367,472, June 27, 1906. Under Int. Conv., April 26, 1906.

The gums of certain Sapotaceæ—such as those of the

Mimusops and Chrysophyllum genera and the gum of Sap. Muelleri— are washed in water, then treated in a boiling 5 per cent. solution of potassium nitrate, and afterwards in a boiling 5 per cent. solution of sodium or potassium silicate, borax, or sodium tungstate, the gum being then drained and boiled in a bath containing 5 per cent. of quicklime. After washing, to remove any excess of alkali, the mass is kneaded and rolled.—C. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 1108.)

UNITED STATES PATENT.

Gelatin and glue from bones; Manufacture of ——. H. Hilbert, Heufeld, Germany. U.S. Pat. 834,806, Oct. 30, 1906.

SEE Eng. Pat. 13,682 of 1903; this J., 1903, 1007.—T. F. B.

FRENCH PATENTS.

Tanning; Rapid process of —— for producing sole leather. S. Boccardo and Co. Fr. Pat. 367,768, July 5, 1906.

THE hides are first subjected to the action of a bath containing sodium chloride, 22·5 per cent; sodium sulphate, 3·0 per cent.; and hydrochloric acid, 1·5 per cent. They are next immersed successively in baths containing:—First bath: tannin, 15·0 per cent.; sodium chloride, 12·0 per cent.; sodium sulphate, 1·5 per cent.; and hydrochloric acid, 0·75 per cent. Second bath: tannin, 30·0 per cent.; sodium chloride, 6·0 per cent. Third bath: tannin, 30·0 per cent. The tanned hides are then well washed to remove the salts and acid. The process takes from two to three days.—W. P. S.

Horn-like masses; Process for the manufacture of —— from casein or similar substances, or from other albuminoid or protein substances. G. W. Betz. Fr. Pat. 367,407, June 23, 1906.

THE solution of casein, after being rendered faintly acid, or after adding a small quantity of ammonia or other basic substance, is treated with formaldehyde. Or, casein is dissolved in acidulated water, and the solution treated with formaldehyde. Or, casein is dissolved in water, precipitated by addition of acid, and redissolved in presence of ammonia or other basic substance, and the solution treated with formaldehyde. The coagulated casein is separated, dried, and hardened, finally under the influence of pressure or heat. The product may also, during or after drying or hardening, be again subjected to the action of formaldehyde. Protein or albuminoid substances, such as albumin, glue, gelatin, gluten, &c., may be used in place of casein.—A. S.

XV.—MANURES, &c.

(*Continued from page* 1108.)

Denitrification process; Influence of carbohydrates and organic acids on the ——. J. Stoklasa and E. Vitek. Z. Zuckerind. Böhm., 1906, **31**, 67—119.

THE micro-organisms investigated were grown in a solution containing sodium nitrate, small quantities of potassium phosphate and sulphate, calcium and magnesium chlorides, sodium carbonate, and iron phosphate, along with the particular carbohydrate or neutralised acid. After a period the nitrogen present in the solution as ammonia, nitric or nitrous acid, and in organic form respectively was determined. The results are incorporated in a series of tables. *Clostridium gelatinosum* proved the best ammonia former in the case of dextrose, *Bacillus subtilis* the best from levulose and galactose. Arabinose is a better medium than xylose, whilst the neutralised organic acids offer less favourable conditions than do the carbohydrates. *Bacterium Hartlebi* gives rise to the formation of much organic nitrogen in arabinose solutions, whilst it decomposes 83 per cent. of the nitrate in xylose solution; for all the other bacteria the pentoses are shown to be an entirely unsuitable material. The acids all form excellent media for the decomposition of the nitrate to elementary nitrogen and the formation of organic nitrogen compounds, *Bact. Hartlebi* being again found to give the highest results. A more detailed investigation into its action showed that the first stage in the denitrification process is the reduction of nitrate to nitrite by hydrogen formed along with carbon dioxide in the decomposition of carbohydrate or organic acid by the enzymes of the micro-organism. It is pointed out that the carbohydrates in the soil are more adapted for the conversion of nitric acid into ammonia than as nutrients for denitrification bacteria.—E. F. A.

Fertilisers; U.S. Census of ——. Oil, Paint, and Drug Rep., Oct. 29, 1906. [T.R.]

THE fertiliser industry in 1905 followed the general tendency towards consolidation, the number of establishments reported being 400, as compared with 422 in 1900. The capital employed in the industry rose from $60,685,753 to $69,023,264, while the value of the products increased from $44,657,385 to $56,632,853. The following table shows the materials used by kind, quantity, and cost, and the products by kind, quantity, and value:—

	1905.	1900.
Materials used, total cost..	$39,343,914	$28,958,473
Fish	$880,142	$183,542

ENGLISH PATENT.

Manure [from sewage sludge]. J. T. Sidebotham, Stalybridge, Cheshire. Eng. Pat. 1970, Jan. 26, 1906.

SEWAGE or "slush cake," as taken from the presses of various sewage works, is mixed with about one-eighth of its weight each of lime and granulated peat moss, and the mass is ground, with the addition, if desired, of a small proportion of ammonium sulphate, sodium nitrate, or steamed bone flour.—E. S.

FRENCH PATENT.

Fœcal matters; Process and apparatus for the treatment of —— for the manufacture of manures. Ets. Charles et Cie. Fr. Pat. 367,670, June 19, 1906. XVIII*B.*, page 1169.

XVI.—SUGAR, STARCH, GUM, &c.

(*Continued from page* 1109.)

Sugar beets; Analysis of ——. D. L. Davoll, jun. J. Amer. Chem. Soc., 1906, **28**, 1606—1611.

FOR the analysis of sugar beets, the author recommends a modification of the warm aqueous digestion method, in which the solution is made up, not by volume, but by weight. It was found that the average weight of 52·096 grms. of pulp, 14 c.c. of basic lead acetate solution, and water, when mixed, digested, cooled to 20° C., and made up to 201·2 c.c., was 209·2 grms., and that the weights ranged between 207·67 grms. (for 11·9 per cent. beets) and 210·08 grms. (for 17·9 per cent. beets). Hence 209·2 grms. may be taken as the correct weight to which the digested pulp is to be adjusted. This method allows of the substitution of beakers for graduated flasks. The weights of a large number of 300 c.c. Jena beakers are ascertained. The heaviest of these is provided with a ⅛ in. glass tube, sealed at both ends and fitted with a rubber tip secured by copper wire, of suitable length, to act as a stirrer. The beaker and stirrer are then weighed together, and this weight is taken as the standard to which all the beakers and their respective stirring rods are to be brought. The weights of the other, lighter beakers, with stirring rods, are adjusted to the standard by introducing the requisite quantities of mercury into the hollow stirring rods before sealing. The beakers and corresponding stirring rods are then etched with consecutive numbers. The pulp is weighed out, rinsed into the beaker, treated with 10—16 c.c. of basic lead acetate solution and so much water from an overflow pipette, that only a few drops are required, after digestion and cooling, to make up the weight to 209·2 grms. The amount of water to be added is first determined by experiment, and allowance must be made for evaporation during digestion. The pulp is digested for 30 minutes at 80° C., and cooled in a cold water bath. The beaker is then dried on the outside, placed on a balance, and made up to weight with water. The analysis is completed as usual. The advantages of the method are :—1. The pulp is much more quickly and easily introduced into the beaker than into a flask. 2. Stirring may be done much more efficiently. 3. Addition of ether is unnecessary. The method is, of course, applicable to sugar-cane and bagasse, in which cases, weight being applied instead of volume, the quantities may be proportionally increased and the difficulty in sampling thereby overcome.—L. E.

Beetroot; Quantity of plus-sugar, calculated as anhydrous raffinose, present in ——. H. and L. Pellet. Bull. Assoc. Chim. Sucr. et Dist., 1906, **24**, 454—460.

IT is now known that the raffinose which is found in beetroot molasses is not formed in the course of manufacture, but that it is pre-existent in the beetroot itself. A. Herzfeld has advanced the opinion that raffinose is present in exceptionally large quantity in beetroots which, after having been subjected to considerable cold, have continued to grow, and that this raffinose results from the transformation of pectin substances previously rendered soluble. This hypothesis has been confirmed by the researches of Wohl and Niessen. Moreover, it is well known that, during the germination of many plants, *e.g.*, potatoes and barley, starch is transformed into sucrose. The authors quote, from a paper by A. Herzfeld (Z. Ver. deut. Zuckerind., 1906, 751), results of analyses of raw beet sugar and molasses of the campaigns 1902—3, 1903—4, 1904—5, and 1905—6, which show that the amount of raffinose in this year's beetroot is exceptionally high. The authors have analysed a sample of German molasses which contained 2·04 per cent. of raffinose (calculated on dry matter), and have shown that a serious error is introduced in the determination of the purity coefficient, if the amount of raffinose is not taken into account. Hence, to obtain the real purity coefficient, the authors recommend the determination of the polarisation (before and after inversion) from which the amount of crystallisable sugar may be found by Herzfeld's formula, and the determination of the real content of water from the loss in weight on drying the sample.—L. E.

Purities, apparent and real; The different ——, which may be calculated for the same product. Variations in the ratio of organic matter to ash and in the saline coefficient, according to the method of analysis. H. Pellet. Bull. Assoc. Chim. Sucr. et Dist., 1906, **24**, 460—465.

THE author has analysed a sample of Egyptian cane molasses by determining *sucrose* by means of direct polarisation either with or without treatment with basic lead acetate, and also by Clerget's method; *reducing sugars* by reduction of an alkaline-copper solution either with or without previous treatment with basic lead acetate; *dry solids*, by determining the density either by the Brix saccharometer, or by a pycnometer, or else by directly drying the molasses in presence of powdered pumice-stone. The results varied as follows :—Crystallisable sugar, 30·6—37 per cent.; reducing sugars, 13—16; water, 18—26; organic matter, 12—28; purity coefficient, 37·5—50; proportion of reducing sugars to 100 parts of sucrose, 39—50; ratio of organic matter to ash, 1·34—3·16. To ascertain the true composition of cane molasses, the author points out that the sucrose must be determined by Clerget's method, and the water, by drying the molasses. To prevent the molasses from undergoing any alteration during drying, one or two drops of ammonia should be added to the sample. The author has also analysed a sample of beetroot molasses containing a considerable proportion of raffinose, the *sucrose* being deter-

mined by Clerget's method, and by means of direct polarisation, and *dry solids* by density according to Brix, or with the pycnometer, or by direct drying. The results obtained by the various methods showed considerable differences. (For determining the true purity coefficient in such cases, see the preceding abstract.) In order to make an accurate determination of the dry matter in beetroot molasses, the latter should first be neutralised with the requisite quantity of sulphuric acid (determined by titration), a drop of ammonia being subsequently added to ensure absolute neutrality. The weight of acid retained by the alkali in the molasses, is deducted from the weight of dry matter.—L. E.

Saturation; Some remarks on ——. E. Bäck. Z. Zuckerind. Böhm., 1906, **31**, 119—124.

In the first saturation of sugar juice with carbon dioxide, subsequent to treatment with lime, it is commonly considered advisable that the degree of alkalinity should not be reduced below 0·1 per cent. of calcium oxide, since it is supposed that, if the saturation be carried beyond this point, a portion of the separated non-sugar is re-dissolved. The author considers that this supposition is ill-founded. During the last 15 years he has carried the first saturation to an alkalinity of 0·06—0·07 per cent. of lime (indicator phenolphthalein) with good results. Analyses of diffusion and thick juices during this period showed that the removal of non-sugar was very satisfactory. The author has confirmed his opinion by the following experiments:—The diffusion juice, heated to 85° C., was treated with 3 per cent. of lime in the form of milk of lime. The juice was then saturated to an alkalinity of 0·1 per cent. of lime (phenolphthalein), a portion of the juice and mud was removed, and the saturation of the remainder was carried to about 0·05 per cent. of lime, a second sample of juice and mud then being taken. Both samples were filtered, the filtrates being saturated to neutrality in order to eliminate the influence of the different amounts of lime in the samples on the analytical results. The saturated filtrates were again filtered, evaporated, and analysed. Three such analyses were made, and in one case, the mud also was analysed. The results showed that the thick juice from the diffusion juice saturated to 0·05 per cent. of lime, contained less non-sugar and nitrogen, and had a higher coefficient of purity than the thick juice from diffusion juice saturated to 0·1 per cent. of lime. Moreover, the mud from the juice saturated to 0·05 per cent. of lime contained less saccharate than that from the juice saturated to 0·1 per cent. The author concludes that the alkalinity may be reduced to 0·05—0·06 per cent. of lime in the first saturation without re-dissolving the non-sugar, and that the coefficient of purity of the juice is higher, and the desaccharification of the mud is easier than when the alkalinity is only reduced to 0·1 per cent.—L. E.

Sugars; Determination of —— by means of the refractometer. L. M. Tolman and W. B. Smith. J. Amer. Chem. Soc., 1906, **28**, 1476—1482.

Stolle (Z. Ver. deutsch. Zuckerind., 1901, 335, 469) has determined the index of refraction of sucrose, dextrose, lævulose, and lactose with the aid of the Pulfrich refractometer, and showed that the relation between the index of refraction and specific gravity as calculated by the Lorenz formula $\frac{N_2 - 1}{(N_2+2)D}$ was a constant, 0·206. The authors have made a series of determinations with the Abbé refractometer on the sugars mentioned and also on maltose, commercial glucose (a mixture of dextrose, maltose, and dextrin), and dextrin. It was found that, for the same concentration, the index of refraction is practically the same for sucrose, maltose, commercial glucose, lactose, dextrose, and lævulose, but is somewhat higher for dextrin. In the following table the values of the index of refraction for solutions of sucrose ranging from 1 per cent. to 90 per cent. strength are given, and for ordinary work this table may be used for all sugars in the same way as the Brix table is used in the case of specific gravity determinations:—

Sucrose, per cent.	Index of refraction at 20° C.	Sucrose, per cent.	Index of refraction at 20°.	Sucrose, per cent.	Index of refraction at 20°.
1	1·3343	31	1·3828	61	1·4442
2	1·3357	32	1·3847	62	1·4465

23	1·3688	53	1·4263	83	1·4981
24	1·3705	54	1·4284	84	1·5007
25	1·3722	55	1·4306	85	1·5034
26	1·3739	56	1·4328	86	1·5061
27	1·3756	57	1·4351	87	1·5088
28	1·3774	58	1·4373	88	1·5115
29	1·3792	59	1·4396	89	1·5142
30	1·3810	60	1·4419	90	1·5170

The temperature correction for index of refraction is practically the same as that for specific gravity. The determination of the index of refraction is stated to possess considerable advantages over that of the specific gravity with respect to speed, ease of manipulation, &c.—A. S.

Gum of Cochlospermum gossypium. H. H. Robinson. Chem. Soc. Trans., 1906, **89**, 1496—1505.

Cochlospermum Gossypium is a small deciduous tree growing abundantly in N.W. Himalaya, and also found in Central India. The gum has been examined by Lemeland (this J., 1904, 904). The gum examined by the author contained 15·5 per cent. of water (loss at 100° C.) and 5·2 per cent. of ash. It was investigated according to the method proposed by O'Sullivan (Chem. Soc. Trans., 1884, **45**, 41; this J., 1892, 48; 1901, 733). It probably consists of the tetra-acetyl derivative of a gummy acid to which the name *α-cochlosperminic acid* was given. This acid, probably $C_{34}H_{54}O_{30}$, was isolated by treating 100 grms. of the gum with 2 litres of 5 per cent. sodium hydroxide solution, and after standing for a long time, nearly neutralising the mucilage with dilute hydrochloric acid, again allowing to stand for a few days, and then adding excess of strong hydrochloric acid solution. The solution was purified by dialysis, and the free gum-acid precipitated by alcohol and a small quantity of hydrochloric acid, washed with alcohol, and dried. It is a white granular substance, having a rotatory power $[\alpha]_D = +57°$; it gelatinises with water, but does not dissolve. On hydrolysis with dilute sulphuric acid, the gum yields 14·4 per cent. of acetic acid, a gum-acid (*gondic acid*), and two sugars—xylose and a hexose, possibly galactose. Gondic acid, $C_{28}H_{46}O_{21}$, is soluble in water, and is precipitated from solution by alcohol as a white amorphous substance. It is an anhydride, and has the rotatory power $[\alpha]_D = +97·7$.—A. S.

Araban; Formation of —— by bacteria, and its relation to gums of the Amygdalæ. W. Ruhland. Ber. dtsch. botan. Ges., 1906, **24**, 393—401. Chem. Centr., 1906, **2**, 1348.

Aderhold and Ruhland have previously isolated from young shoots of diseased cherry trees, a fission fungus, *Bacillus spongiosus*, Aderh. and Ruhl., which when sown in various parts of a cherry tree causes the production of a gum consisting of a mixture of araban and galactan. The author has grown this bacillus on bouillon-agar with additions of pentoses, hexoses, disaccharides, raffinose, glycerol, ammonium lactate, and mannitol. In presence of sucrose, a slime was produced immediately, and also, after some time, in presence of raffinose. No slime was

produced on the media containing dextrose or a mixture of dextrose and levulose, and either none or a very small quantity on media containing levulose alone. Slime was produced on media containing mannitol, but only in small quantity. The best concentration of sugar for the production of slime is very high; much more slime is produced in presence of 30 per cent. than in presence of from 5 to 30 per cent. of sugar. The gum contained in the slime was pure araban, no galactan, hemicelluloses, or nitrogenous substances being present. It appears, therefore, that a bacillus producing a gum-flux in plants forms a different gum when grown in an artificial nutrient medium, and the author considers that Grieg Smith's view of the bacterial origin of gums is not proved. (See this J., 1904, 105, 972.)—A. S.

Charcoals; Adsorptive properties of various ——. L. Rosenthaler and F. Türk. XX., page 1172.

Molasses for fermentation; Observations on the preparation of ——. G. Garbarini. XVII., page 1166.

Sucroclastic action of acids as influenced by salts and non-electrolytes. R. J. Caldwell. XXIV., page 1177.

Levulinic acid; Iodometric determination of ——. B. Savarè. XX., page 1172.

Denitrification process; Influence of carbohydrates and organic acids on the ——. J. Stoklasa and E. Vitek. XV., page 1162.

Starch; U.S. Census of ——. Oil, Paint, and Drug Rep., Oct. 29, 1906. [T. R.]

In 1905 there were 131 establishments engaged in the manufacture of starch, but the product was valued at only $8,082,904, as compared with 124 establishments having an output valued at $9,232,984 in 1900. The reason for this apparent reduction in output is that starch to the value of $4,224,200 was produced in 1905 in glucose factories, as compared with $2,850,888 worth produced in the same factories in 1900. This exception should be borne in mind in connection with the statistics in the following table showing the materials by kind, quantity, and cost, and products by kind, quantity, and value:—

United States Patent.

Grape-sugar [Dextrose]; Process of manufacturing anhydrous ——. T. B. Wagner, Chicago, Ill. U.S. Pat. 836,145, Nov. 6, 1906.

The process consists in preparing a solution of dextrose at a temperature of 110°—130° F., adding "seed" crystals, and agitating the solution at the said temperature until the dextrose has crystallised out. The mother-liquor is subsequently removed.—W. P. S.

French Patent.

Coal; New artificial —— composed of a mixture of beet-pulp, fine coal, wood charcoal, or coke, and a binding medium. J. P. Reneaux. Addition, dated June 19, 1906, to Fr. Pat. 366,141, April 28, 1906. II., page 1139.

German Patent.

Crystals; Apparatus for obtaining uniform —— from solutions, especially from sugar solutions. M. W. Verwer. Ger. Pat. 167,050, March 18, 1903.

The solution from which crystals are to be obtained is contained in a cylindrical drum, through which passes a central rotating shaft of octagonal cross-section. Alternate faces of the shaft carry arms, to which are fixed the strings, rods, &c., on which the crystals form. By rotating the shaft, the strings, &c., can be moved from the lower to the upper part of the containing vessel, as desired, and the obtainment of uniform crystals is thus rendered possible. —A. S.

XVII.—BREWING, WINES, SPIRITS, &c.

(*Continued from page* 1113.)

Malt rootlets. M. Bermann. Woch. f. Brau., 1906, 23, 602—603.

The careful observation and regulation of the rootlet growth is an important duty of the maltster, as the quality and modification of the malt may be affected by faulty growth, but owing to the fact that the dried roots (combs) are removed, the fault is not easily traced by the analyst. It is true that a determination of the coagulable and uncoagulable albuminoids may afford some indication, but this is too laborious for ordinary use. The natural tendency for the rootlet to grow towards the centre of the earth and the acrospire away from it exists in the malting process. But the direction of the acrospire is determined by its position in the husk, whereas that of the rootlet is changed every time the grain is turned, thus producing the well-known "curliness." This curliness is therefore a record of the frequency of the turning and the stages at which this is performed, and is an indication of all that the turning entails. Numerous and small spirals denote frequent turning of the couches, and are characteristic of the Bohemian malts, whilst longer spirals show that the couches have been allowed to lie more solid, as in the preparation of Bavarian malts. Long, straight rootlets always indicate faulty malt. In this case, if the malt shows a correct length of acrospire but inferior modification, it shows that the barley was steely and that the maltster was obliged to make what is called "felted malt." If the modification is correct, the fault is due either to carelessness or to a desire to curtail the time of malting by not turning the couches at an early stage. The growth of the rootlet is not uniformly rapid; it is slow at first, reaches a maximum intensity on the third or fourth day, and subsequently slackens. A good rootlet growth should be uniform and bushy; if two or three of the filaments are long and the others scarcely developed, the malt is inferior; this generally indicates either unmatured barley or overloading the floor out of harmony with the temperature. No rule can be laid down for the length of the rootlet; it generally varies between 1½ and 2 corn-lengths; the growth must be adjusted to the nature of the barley and the uses of the malt. Within certain limits the development of the rootlet and acrospire can be varied independently; the rootlet responds more to a full steep or early sprinkling, whilst the acrospire growth is favoured by incomplete steeping and repeated sprinkling at a later stage. Frequent turning over at first and only allowing the malt to lie after the fifth day has been reached, favour the development of the acrospire as compared with

that of the rootlet, whilst leaving the couches alone in the early stages has the opposite effect. Lastly, the rootlet growth should remain fresh and vigorous right up to the withering stage, and should have a characteristic "cucumber" odour. Premature withering with a bad odour is a sign of forced working or overloading of the floor.—J. F. B.

Malt; Rapid method for the determination of the colour of ——. M. Bermann. Woch. f. Brau., 1906, **23**, 584—585.

In making malt of a definite colour, a rapid, if not quite accurate, method for the determination of colour is desirable. The author proceeds in the following manner:—A certain weight of malt is ground in the Seck mill, and is at once mixed with 400 c.c. of water at a temperature of 75° C. The mash is stirred continuously for five minutes, and filtered at once without cooling, the colour being then determined in a colorimeter. As regards the weight of malt which should be taken, the author remarks that this method does not give the same results as the standard laboratory mashing method, since only the more friable portions of the corns are dissolved. The quantity of malt mashed in 400 c.c. of water must therefore be larger, and the increased weight must be adjusted according to the condition of the endosperm. The quantities empirically determined for various types of well-modified malt are about 55 grms. for Munich malt, 60 grms. for Vienna, and 67 grms. for Pilsener. With only moderately modified malts these quantities should be increased by 5 grms. This rapid method of colour determination is especially convenient in the preparation of Bavarian malts, the colour of which is largely subject to control during the curing process. One of the kilns is started half an hour before the others, all being worked in the same manner. The malt from the kiln in advance is then tested for colour at intervals of half an hour, and the other kilns are stopped according to the indications thus obtained.—J. F. B.

Extract in the mashing process; Simple method for increasing the yield of ——. R. Heerde. Woch. f. Brau., 1906, **23**, 628.

For breweries in which two mash tuns are worked continuously, and in which filter-presses are not used, the author recommends the employment of two filtering vats instead of one, in order to increase the filtering surface and reduce the depth of the layer of grain. The mashing processes in each tun are worked alternately, a fresh mash being started in each tun once in eight hours, so that the filtering vats receive a fresh charge every four hours. The wort from both vats is run into one copper. By using two vats, the speed and efficiency of filtration are increased, and a finer malt grist may be employed. Thus, the yield of extract is increased, and the rapid filtration has a favourable effect on the taste of the beer, and, in the case of pale beers, on the colour also.—L. E.

Molasses for fermentation; Observations on the preparation of ——. G. Garbarini. Bull. Assoc. Chim. Sucr. et Dist., 1906, **24**, 521—523.

It often happens that molasses are infected with organisms which are so resistant to heat that they are not destroyed during the sterilisation previous to fermentation. In such cases it is usual to increase the quantity of sulphuric acid added to the liquor. This involves, in addition to the extra consumption of acid, a reduction of the value of the saline residue. Moreover, the calcium sulphate, formed by the addition of sulphuric acid to the liquor, causes incrustation on the evaporating pans. To remedy these defects, the author proposes the following method:—After diluting the molasses to a gravity of 1·25—1·30, sulphuric acid is added to the extent of 2—2·5 grms. per litre, and the liquor is heated and treated with an agglutinating agent such as blood, or colophony dissolved in caustic soda. The liquor is then passed through a sand filter, the greater part of the calcium sulphate and a large number of organisms, being thus removed. A quarter of the filtered liquid is again treated with acid, so that when diluted to a gravity of about 1.060, its acidity will amount to 2·5—3 grms. of sulphuric acid per litre; it is then sterilised and afterwards used for growing the pure yeast employed for fermentation. The remainder of the liquor is diluted with the hot condenser water from the distillation column, and sterilised. Both liquors (gravities about 1.080) are run into the fermenting vat; three-fourths of the mixture will have an acidity of 0·5—0·6 grm. per litre, whilst that of the remainder will be 2·5—3·0 grms. per litre (expressed as sulphuric acid).—L. E.

Distillery and pressed yeasts; Influence of acids and other substances on infected ——. W. Henneberg. Woch. f. Brau., 1906, **22**, 527—529, 568—571, 580—584, 597—602.

The best means of cleansing the yeast in distilleries and pressed-yeast factories, which do not employ pure cultures, is by the use of suitable poisons which have a stronger action on the infecting organisms than on the culture yeast. The poisons may be applied either by steeping the yeast in a solution of the substance for a sufficient time to kill the infection, or by conducting fermentations in presence of small quantities of the poison sufficient to restrict the growth of the bacteria, and to allow the yeast to get the upper hand. The author has studied the conditions as to time and concentration under which these substances can be used to the best advantage, and their relative efficiencies for separating the culture yeast in the pure state. Hydrofluoric acid is of little use for cleansing the yeast by steeping, because the yeast is more sensitive than the bacteria; when fermentations are conducted in presence of hydrofluoric acid the yeast is slightly more resistant. Hydrochloric acid gives a good separation of yeast from bacteria by the steeping process; for cleansing by fermentation it is moderately good. Sulphuric acid gives an excellent separation both by the steeping and the fermentation processes. Nitric acid resembles hydrochloric acid in its action. Phosphoric acid is not of much use for purifying yeast by the steeping process, but in purifying by fermentations it can be used at concentrations of 0·2 per cent. Formic, acetic, and butyric acids afford no separation by either process. Lactic acid is only moderately good for cleansing by the steeping process, but, as is well known, it is one of the most valuable means for purifying by means of fermentation. The proportion used in practice for obtaining pure fermentations depends on the method of mashing and the nature of the raw material; in grain mashes the concentration may lie between 0·47 and 0·13 per cent. of lactic acid. Oxalic acid is suitable for cleansing by steeping, but quite unsuitable for fermentations. With tartaric acid successful treatment by steeping is only obtained by the prolonged action of solutions containing more than 2·5 per cent., but concentrations over 0·5 per cent. give good results by the fermentation process. Citric acid is weaker in its action than tartaric acid: cleansing is obtained by the action of 2·5—5·0 per cent. solutions in 24 hours; in fermentations, purification takes place in presence of 1 per cent. Alcohol cannot be used for purification by either process. Formaldehyde is very powerful in its action, but does not afford a good separation of yeast from bacteria. On the other hand, the addition of 0·005 per cent. of formaldehyde to the mashes is a most valuable means for preventing the flocculation of the yeast which takes place under the action of a species of lactic acid bacteria. Caustic soda is quite unsuitable for cleansing the yeast from infection.—J. F. B.

Beer; Method for the separation of mycoderma and acetifying bacteria in ——. C. Bergsten. Woch. f. Brau., 1906, **23**, 596—597.

When acetifying bacteria are present in beer they are nearly always accompanied by mycoderma yeasts. In an examination of such beers the liquid becomes covered with a film of mycoderma which grows more rapidly than the bacteria, and may suppress them. An analytical separation of the two is obtained by favouring the growth of the bacteria by the addition to the beer of dilute acetic acid, towards which mycoderma yeasts are very sensitive. The quantity of acid necessary to suppress the growth of mycoderma depends on the temperature employed,

since high temperatures are also inimical to the mycoderma. A temperature of 40° C. is sufficient to prevent the development of mycoderma without the addition of acid; at 25° C., 15 per cent. of *N*-acetic acid must be added; at 15° C., 25 per cent. Cultures should be made at various temperatures, since some species of acetifying bacteria are favoured by low temperatures and others by high temperatures. In the acidified cultures the beer becomes covered with a thin, delicate film of bacteria, whilst in the unacidified sample, incubated at 20° C., a thick, white, leathery film of mycoderma is formed. The films can be tested under the microscope with iodine solution. Most of the acetifying bacteria are stained yellow, *B. Pasteurianum* and *B. Kützingianum* are stained blue, whilst *B. xylinum* gives the blue cellulose reaction after treatment with sulphuric acid. Mycoderma yeasts are rich in glycogen, and the films therefore give a brown reaction with iodine.—J. F. B.

Sarcina; Detection of ——. H. Will and M. Rigaud. Z. ges. Brauw., 1906, **29**, 577—582 and 599—601.

The nutrient liquid recommended by Bettges and Heller (this J., 1906, 227) for the detection of sarcina in brewery yeast seems to be generally applicable. When this liquid is used for an object glass preparation sealed by means of vaseline in the manner recommended by Lindner, the sarcina can be detected earlier and more certainly than when yeast water is employed. Such sealed preparations are to be preferred to inoculations into Freudenreich flasks. A slight degree of acidity or alkalinity of the culture liquid does not interfere with the development of the sarcina under the above conditions. Schönfeld (this J., 1898, 781) showed that sarcina in beer could be detected by completely filling a bottle with the beer, closing the bottle with a paraffined cork, and keeping it at room temperature. Under these conditions, the sarcina develops rapidly both in the deposit and in the beer, and in some cases the beer becomes quite turbid. It was shown later by Luff (Z. ges. Brauw., 1902, **25**, 82) that, after a beer is forced, any sarcina originally present is found in abundance in the deposit. The authors find, however, that the time required for any considerable increase of the sarcina to occur in this way is at least two to three weeks, so that the method of Bettges and Heller (*loc. cit.*) is to be recommended.—T. H. P.

Fusel oil; Production of —— in fermentations with sterilised yeast preparations. H. Pringsheim. Ber., 1906, **39**, 3713—3715.

Buchner and Meisenheimer (this J., 1906, 998) had observed that in the fermentation of sugar by yeast cell-juice only minute traces of fusel oil are produced. The author has studied the same question in fermentations by "Aceton-dauerhefe," a preparation of dry yeast sterilised by treatment with acetone. The experiments were made both with pure sugar and with the addition of increasing quantities of leucine, which is regarded by Ehrlich (this J., 1905, 683) as the mother substance of amyl alcohol in fermentations. The fusel oil determinations were made by Beckmann's method, but in no case did the quantity of amyl alcohol found exceed the normal limit of error of the method. On the other hand, in fermentations by living yeast cells conducted in presence of leucine, considerable quantities of amyl alcohol were found.—J. F. B.

Wines containing a high percentage of alcohol. N. Passerini. Staz. sperim. agrar. ital., 1906, **39**, 350—354. Chem. Centr., 1906, **2**, 1514—1515.

In general it is accepted that if a wine contain more than 15—16 per cent. (by vol.) of alcohol, it has been fortified by addition of alcohol. According to the author, however, choice wines, named "vinsanti," prepared in Tuscany and other districts of Italy, chiefly from grapes of the Trebbiano variety, contain a higher proportion of alcohol than is customary in wines. For the preparation of "vinsanti," the dried grapes are pressed, usually in the early part of November, and the must allowed to ferment in wooden casks of ½—1 hectol. capacity. After three years the wine is bottled, generally in November. The author has examined samples of genuine "vinsanti" of the years 1868—1905. Of 30 samples, 17 contained more than 15 per cent. (by vol.) of alcohol, nine contained more than 17 per cent., and two contained over 20 per cent. The highest alcohol content was 21·4 per cent. in a wine of the year 1868. This wine had the following composition:—Percentage of alcohol by weight, 17·4; dry extract, 125·76 parts per 1000; ash, 2·57; total acid (as tartaric acid), 8·84; volatile acid (as acetic acid), 2·6; potassium bitartrate, 0·94; dextrose, 76·15, and glycerol, 11·22 parts per 1000. The ratio of glycerol to alcohol in the wine was thus 6·4:100; in two other wines the ratio had the values 7·4 and 6 respectively: 100.—A. S.

Œnocyanin, the colouring matter of red wine; Extraction and utilisation of ——. M. Cari-Mantrand. Bull. Soc. Chim., 1906, **35**, 1017—1022.

It has not been found possible to extract the colouring matter from grape mares and lees of wine with satisfactory results, but red wines destined for distillation serve as a convenient source of œnocyanin. The author proceeds in the following manner:—The wine is treated with sufficient basic lead acetate to precipitate the colouring matter; the precipitate is collected on a filter, and is washed until the filtrate contains only traces of lead. This operation takes place very slowly, requiring about 24 hours. The precipitate is weighed moist, and the dry substance and lead oxide are determined in an aliquot portion. The remainder is then treated with exactly the calculated equivalent of sulphuric acid, and the liquid is filtered hot. The colouring matter passes into the filtrate, and the lead sulphate is washed with hot water. During the concentration of the solution, the œnocyanin tends to resinify and to become converted into a tarry mass, insoluble in water and only partially soluble in alcohol. This tendency is entirely prevented by the addition of 10 grms. of glycerol to the extract from 1 litre of wine, and the liquid can be evaporated to the consistency of a fluid extract perfectly soluble in water or wine. This extract can be employed for increasing the colour of poor wines, also for colouring confectionery, liqueurs, &c. The determination of the œnocyanin should be included in the analysis of red wines, as it forms part of the solid extractive matter; proportions ranging from 9·2 to 18·7 grms. per litre have been recorded. Œnocyanin is not a uniform substance. In certain wines a portion of it separates from the hot filtrate from the lead sulphate after cooling. This insoluble portion should be filtered off, dissolved in strong alcohol, and evaporated in presence of glycerol, the product being then mixed with the rest of the extract.—J. F. B.

Whiskey; Methods for the determination of esters, aldehydes, and furfural in ——. L. M. Tolman and T. C. Trescot. J. Amer. Chem. Soc., 1906, **28**, 1619—1630.

Esters.—The following method is proposed: Add 25 c.c. of water to 200 c.c. of the sample, and distil off 200 c.c. into a receiver provided with a mercury seal. Neutralise 50—100 c.c. of the distillate in presence of phenolphthalein, and add excess of *N*/10 caustic soda. Allow to stand all night and heat for half an hour under a reflux condenser. Lastly, determine the excess of alkali by titration. No method is proposed for the separation of fixed esters, if any are present, from colouring or resinous matters which also react with caustic soda.

Aldehydes.—The temperature (15° C.) at which the solutions are mixed and compared is an essential factor. Comparisons should be made in a colorimeter. The determinations are carried out on the distillate prepared for the ester determination. It is not possible to effect the determination on the undistilled sample clarified by basic lead acetate (Schidrowitz; this J., 1902, 814), because spirits, coloured artificially by caramel, are not decolorised by the lead solution. Experiments have shown that the quantity of alhehyde is in no way altered by the distillation.

Furfural.—This determination is made on the distillate; the temperature of 15° C. is important. The authors prefer to employ hydrochloric acid instead of acetic acid for making the aniline reagent, since some samples of acetic acid give a coloration with aniline. In all colorimetric determinations the time allowed for comparison with standards should be 15 minutes. The proportion of furfural is not affected by distillation.—J. F. B.

Filters for beer and other sedimentary liquids. H. C. Russell, London. Eng. Pat. 15,046, July 2, 1906.

THIS specification describes a combined filter and press for the paper pulp or other filtering material, provided with inlet and outlet pipes for the liquid, a filter cover adapted to receive the press plate, and means for raising and lowering and putting final pressure on the press plate. The filter is made up of a series of filtering sections placed in juxtaposition and separated by metal gauze spacing discs, a metal gauze shell, and top and bottom gauze discs, a perforated base-plate, and a flanged cover-plate adapted to be closed tightly on the body of the filter casing by the press plate. A central core-tube is used to prevent the compressed material passing through the central rings to the liquid-outlet pipe. An interrupted screw-threaded spindle on the press plate engages at its upper part with a pinion above the press crosshead and at its lower part with the interrupted threaded interior of a sleeve which is provided with internal thrust keys or stops and is externally threaded and works through a threaded aperture in the crosshead of the press, this sleeve being provided with a wheel or lever whereby it can be rotated to cause the sleeve to engage with or be disengaged from the screwed spindle on the press cover, and to raise or lower the sleeve and the screwed spindle and press cover together.—T. H. P.

Whiskey; Treatment of —— for the purpose of removing the noxious elements from the higher alcohols. J. B. Hilliard, Glasgow. Eng. Pat. 6770, March 21, 1906.

IN this process, the higher alcohols, together with noxious materials and impurities, are collected separately from the main bulk of alcohol during the distillation, and are treated with pure oxygen gas, whereby, it is stated, the noxious substances are deposited at the bottom of the vessel, and can be run off; the purified higher alcohols are then added to the bulk of pure alcohol.—T. H. P.

Vinegar; Process and apparatus for manufacturing fermentation ——, employing stationary coatings of pure vinegar-generating bacteria. H. Frings, jun., Aachen, Germany. Eng. Pat. 13,178, June 7, 1906. Under Int. Conv., June 7, 1905.

Wheat proteins; Investigations on the properties of ——. J. S. Chamberlain. J. Amer. Chem. Soc., 1906, **28**, 1657—1667.

FOR the proper extraction of the proteins of wheat by alcohol, cold 70 per cent. alcohol should be used on the air-dry wheat or flour, either hot alcohol or dry flour giving abnormal results. The best results are obtained by using large amounts of solvent, *viz.*, 100 c.c. of alcohol to 2—4 grms. of flour. The same conditions of extraction apply to saline solutions, 4—6 grms. of flour being extracted with 100 c.c. of 5 per cent. potassium sulphate for 24 hours; the use of potassium sulphate is preferable to that of sodium chloride, as it avoids the evolution of hydrochloric acid in the Kjeldahl operation. Alcohol extracts a large proportion of the proteins soluble in salt solution, probably the albumin and proteose, as well as gliadin. The author considers the separation of wheat proteins into more than two groups,—*viz.*, (1) alcohol-soluble, and (2) alcohol-insoluble, to be unwarranted. Dry gluten, as procured by washing whole wheat or flour in a stream of water, is about 75 per cent. proteins and 25 per cent. non-proteins, whilst of the total proteins of wheat, from 60—65 per cent. are contained in the gluten, and 35—40 per cent. lost in the washings. The balance between the non-proteins present in the gluten and the loss of proteins in washing makes gluten determinations agree roughly with total proteins calculated from total nitrogen, but they will usually fall below with whole wheat and above with flours. The loss of proteins in the determination of gluten is at the expense of gliadin or glutenin.—E. F. A.

Colouring matters in pastry-ware; Use of carbon tetrachloride for the detection of —— which are forbidden by public health laws. A. Piutti and G. Bentivogolio. Gaz. chim. ital., 1906, **36** [2], 385—391.

SINCE 1888, the use of Martius' Yellow, Metanil Yellow, Victoria Yellow, and picric acid for colouring foodstuffs has been forbidden in Italy. The usual methods for the detection of these colouring matters are unreliable in the case of mixtures, such as are frequently used for the colouring of pastry-ware. The following method is recommended by the authors: 50 grms. of the material under examination are mixed with 500 c.c. of boiling water, made alkaline with 2 c.c. of concentrated ammonia solution, boiled for 40 minutes with 60—70 c.c. of alcohol, rapidly filtered through cotton-wool, and the solution acidified with 2—3 c.c. of dilute hydrochloric acid. Five or six pieces of wool, free from fat, each weighing 0·5 grm., are now dyed in the solution; the dyed pieces are washed repeatedly with water, and then boiled with ammoniacal water to extract the colour. The solution is next acidified in order to again deposit the colour on the wool, and the dyed pieces of wool are again boiled with ammoniacal water. The extract is now evaporated to dryness, and the residue treated with water to obtain a solution of the colouring matters, which solution is acidified with acetic acid and shaken vigorously with carbon tetrachloride. The detection of the different colouring matters follows according to the scheme:—

Acetic acid solution of colouring matters shaken with carbon tetrachloride.				
Colourless carbon tetrachloride solution shaken with ammoniacal water, and aqueous solution divided into two parts :—		Aqueous solution evaporated to dryness, residue dissolved in water, and divided into three portions :—		
I. Pink precipitate with stannous chloride and ammonia = Martius Yellow.	II. Pink coloration (solution) with zinc and hydrochloric acid = Victoria Yellow.	I. Violet coloration with hydrochloric acid = Metanil Yellow (Tropäolin G.)	II. Reddish-brown coloration with ammonium sulphide = picric acid.	III. Reduced with Zn + NH_3, then with Zn + HCl ; yellow coloration with KOH, and orange with $FeCl_3$ = Naphthol Yellow S.

—A. S.

Cocoa ; The carbohydrates occurring in ——. A. D. Maurenbrecher and B. Tollens. Ber., 1906, **39**, 3576—3581.

Cocoa nibs, after removal of husk and fat, were found to contain 5·51 per cent. of pentosans. A solution was obtained, on hydrolysis of the fat-free powder, in which *l*-arabinose, *d*-galactose, and dextrose were detected : xylose did not appear to be present. The thin husk surrounding the beans yielded 9·09 per cent. of pentosans, and the products of hydrolysis contained *l*-arabinose, *d*-galactose, dextrose, and probably xylose. These same sugars were also found in the fleshy part of the cocoa pod, after hydrolysis of the latter. Araban and galactan are, therefore, present in the nibs, husk, and fleshy part of the cocoa fruit. Only traces of water-soluble carbohydrates were obtained directly from the cocoa powder. The fat extracted from the cocoa nibs yielded a quantity of phytosterol, which, apparently, contained a little cholesterol.—W. P. S.

Tea ; The carbohydrates occurring in ——. A. D. Maurenbrecher and B. Tollens. Ber., 1906, **39**, 3581—3582.

A sample of Java tea (*Thea assamica*) examined by the authors contained 5·60 per cent. of pentosans, calculated on the dry substance. On extraction with water, the leaves yielded a trace of sugar which was proved to be dextrose. Further quantities of dextrose, together with arabinose and *d*-galactose, were obtained after submitting the leaves to hydrolysis. Araban, galactan, and a carbohydrate yielding dextrose, are consequently present in the leaves.—W. P. S.

Fæcal matters ; Process and apparatus for the treatment of —— for the manufacture of manures. Em. Charles et Cie. Fr. Pat. 367,670, June 19, 1906.

The plant described comprises a large central tank, at the four corners of which are other tanks for receiving the separated solid matters, whilst on three sides of the main tank are disposed filtering tanks. The sewage, &c., enters the main tank through a pipe in the cover, and flows through an inclined hearth or screen arranged centrally in the upper part of the tank. Any noxious gases evolved pass away, through a central outlet pipe in the cover, to a furnace wherein they are burnt. The coarse solid matters remaining on the hearth or screen are removed from time to time through manholes in the cover of the tank, which holes also serve for the introduction of chemical reagents for the treatment of the sewage. These reagents fall on to a distributing table below the screen, which table is divided into compartments by curved radial arms, and is caused to rotate by the inflowing current of sewage. After the solid matter has deposited on the bottom of the tank, the liquid flows into one or other of the filtering chambers, wherein it passes in succession through layers of coke of medium size, fine coke, coarse sand, fine sand, powdered coke, powdered wood-charcoal, and "wood wool." The solid matter collected on the bottom of the main tank is conveyed to the tanks mentioned above, and therein is mixed by suitable means with calcium sulphate, calcium phosphate, &c., for the production of manures. Provision is made for cleaning the filtering layers in any one of the filtering tanks, without interrupting the process.—A. S.

(*Continued from page* 1115.)

Camphor [in celluloid] ; Determination of ——. A. Arnost. Z. Unters. Nahr. u. Genussm., 1906, **12**, 532—539.

In the method described by the author, the camphor is obtained in alcoholic solution, which is shaken out with petroleum spirit, and the increase in volume of the spirit read off in a special apparatus. This increase, subject to certain corrections, represents the volume of the camphor dissolved out by the petroleum spirit. The details of the process are as follows :—Ten grms. of the finely rasped celluloid are mixed in an Erlenmeyer flask with 100 grms. of 25 per cent. sodium hydroxide solution, and the mixture allowed to stand for one hour, with frequent agitation. The flask is now closed with a cork pierced with two holes, through which pass a delivery tube and a tapped funnel, respectively. After attaching the delivery tube to a condenser, the contents of the flask are heated to a temperature of about 80° C. until the celluloid is completely saponified ; this is seen by the mass becoming homogeneous. The heat is now increased, and the camphor volatilised into the delivery tube and condenser. A few c.c. of alcohol are then added to the contents of the flask by means of the tapped funnel, and distilled off. This

addition of alcohol is repeated several times, until the whole of the volatilised camphor has been carried over into the receiver, a 100 c.c. flask serving the latter purpose. The distillate is diluted to 100 c.c. with alcohol, and the quantity of camphor in it determined in the following manner. The piece of apparatus shown in the illustration is thoroughly dried and suspended vertically in a water-bath at a temperature of 15° C. By the aid of a long-stemmed funnel, the bulb B, is filled up to the 90 mark with acidulated water; 5 c.c. of dilute sulphuric acid to 100 c.c. of water is a suitable strength, and a trace of an aniline dyestuff may be added to facilitate the reading. Ten c.c. of the alcoholic camphor solution are now added and, finally, 50 c.c. of petroleum spirit. The apparatus is next closed with an india-rubber stopper, shaken for two minutes, and allowed to stand in the water-bath at 15° C. for 30 minutes, when the increase of the volume of the petroleum spirit is read off. As a certain amount of contraction takes place when the alcoholic solution mixes with the water, a correction must be applied, the amount to be subtracted from the increase in volume of the petroleum spirit depending on the actual quantity of alcohol present. To ascertain this, the contents of the apparatus are transferred to a separating funnel, 50 c.c. of the aqueous portion are measured off, placed in a distillation flask, rendered alkaline with sodium hydroxide, and distilled, the distillate being collected in a 50 c.c. flask. The specific gravity of the distillate will then give the quantity of alcohol present, and, from the quantity of alcohol, the contraction due to it is ascertained by reference to tables. (See below.) Results of analyses are given, which show that the method yields accurate results; although after four hours' distillation the contents of the flask have still a distinct odour of camphor, the experiments recorded show that at least 99·6 per cent. of the camphor distils

over in three hours. In calculating the weight of camphor present, it must be remembered that the reading gives the *volume*; the sp. gr. of camphor at 15° C. is 0·993. The above contractions are expressed in cubic millimetres. In the original tables the contraction is given for each 0·05 c.c. difference in the quantity of alcohol.—W. P. S.

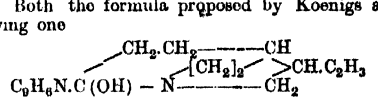
French Patent.



Finishing soap [for textiles and paper]; Manufacture of a ——. E. Agostini. Fr. Pat. 361,772, Sept. 16, 1905. XII., page 1160.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 1117.)

Cinchona alkaloids [*First communication*]. P. Rabe. Annalen, 1906, **350**, 180—203.

After discussing the work done by other investigators, the author gives two formulæ for cinchonine, the first of which has been put forward by Koenigs (see this J., 1906, 825). Both the formula proposed by Koenigs and the following one

put forward by the author are supported by the facts that on oxidation cinchonine yields cinchoninic acid and meroquinene, and that on boiling with acetic acid, cinchonine rearranges itself into cinchotoxine, :C(OH).N: → :CO HN:. The formula proposed by Koenigs explains the behaviour of cinchene on hydrolysis. But the second formula is a simple explanation of the two following facts: that cinchotoxine forms but one mono-isonitroso compound, and that isonitroso-cinchotoxine is decomposed into cinchoninic acid and the nitrite of meroquinene by the Beckmann reaction. At present it cannot be decided which of these two formulæ is correct. Methylcinchotoxine on treatment with amyl nitrite yields isonitrosomethylcinchotoxine melting at about 150° C. This was shaken with phosphorus pentachloride and chloroform, and the resulting liquid treated with ice-water and caustic soda solution. The *nitrile* of *N-methylmeroquinene*, $C_{10}H_{16}N_2$, was obtained on steam distillation. The nitrile is a clear liquid base with a characteristic smell resembling piperidine; it boils at 252°—255° C. at 741 mm., and 102° C. at 49 mm., it has sp. gr. 0·9505 at 20° C., and $[\alpha]_D^{20°} = +17·41°$. It was hydrolysed into N-methylmeroquinene, of which several salts and the ethyl ester are described. *Isonitrosoethylcinchotoxine*, $C_{21}H_{25}N_3O_2$, crystallises from alcohol in fine needles melting at 136° C. On decomposing, the *nitrile* of *N-ethylmeroquinene*, $C_{11}H_{18}N_2$, was obtained, boiling at 268° C. at 750 mm. It is a base with a piperidine-like smell. The salts of N-ethylmeroquinene ethyl ester are described. From isonitrosocinchotoxine, the *nitrile* of *meroquinene*, $C_9H_{14}N_2$, can be obtained. This resembles the two other nitriles and boils at 147°—150° C. at 12 mm. The three nitriles are miscible with water and volatile with steam.—F. Shdn.

Quinine acetylsalicylate; Basic —— L. Santi. Boll. chim. farm., 1906, **45**, 557. J. Pharm. Chim., 1906, **24**, 462.

Although theoretically both neutral and basic quinine acetylsalicylates can exist, it is found that, in practice, only the latter salt, $CH_3.CO_2.C_6H_4.CO_2H(C_{20}H_{24}N_2O_2)$, is obtained, in whatever proportions the constituents are

mixed. It is a white, bitter salt; m. pt., 157° C. Solubility in water, 3:1000; in alcohol, 2.5:100; in chloroform, 10:100; almost insoluble in ether. It is best obtained by mixing equimolecular proportions of acetylsalicylic acid and hydrated quinine, previously dissolved separately in ether. Basic quinine acetylsalicylate then separates as an oily liquid, which speedily assumes the form of a crystalline mass. The salt is useful as an antipyretic.—J. O. B.

Strychnine; A colloidal preparation of ——, *and its pharmacology.* O. H. Brown. J. of Biol. Chem., 1906, **2**, 149—157. Chem. Centr., 1906, 2, 1340.

If a mixture of hydrogen peroxide, albumin, and strychnine be allowed to stand, after about six weeks it is converted into a jelly, or a white flocculent precipitate separates. Adrenaline chloride behaves in a similar manner to strychnine. The strychnine is not oxidised by the hydrogen peroxide. The strychnine contained in the jelly has a much weaker toxic action than pure strychnine.—A. S.

Pareira root; The alkaloids of ——. M. Scholtz. Arch. Pharm., 1906, **244**, 555—560.

The author has previously shown (Arch. Pharm., 1898, 530, and 1899, 199) that the alkaloid bebeerine, isolated from Pareira root, exists in two forms, one amorphous, m. pt., 180° C., and the other crystallised from methyl alcohol, m. pt., 214° C. Further studies have confirmed the tertiary nature of the base by the preparation of quaternary derivatives with methyl iodide and benzyl iodide. The crude alkaloid extracted from the root by dilute sulphuric acid only yielded about 10 per cent. of bebeerine soluble in ether. The residual alkaloid was soluble only in pyridine, and, when purified, it melted at 300° C. Its composition and chemical properties were similar to those of bebeerine, but its physical properties and solubilities were entirely different. The bebeerine isolated some years ago was lævo-rotatory, $[\alpha]_D = -298°$, whereas that obtained in the present case was dextrorotatory to an equal extent, the melting points being identical. When equal quantities of these two antipodes are dissolved in chloroform and mixed together, a precipitate of the racemic alkaloid is obtained, m. pt. 300° C., identical in all respects with the sparingly soluble residual alkaloid mentioned above. The alkaloids of Pareira root, therefore, consist chiefly of *r*-bebeerine, together with an excess of either the *d*- or the *l*-modification according to circumstances. These modifications differ from each other in their physiological properties.—J. F. B.

Aconitine; A new reaction of ——. N. Monti. Gaz. chim. ital., 1906, **36** [2], 477—480.

Most of the reactions for aconitine, including the one proposed by Pinerua y Alvarez (this J., 1905, 562), are stated to be not characteristic of that alkaloid. The following test is recommended by the author:—From 0·0002 to 0·001 grm. of the alkaloid is treated in a porcelain capsule with 2—4 drops of sulphuric acid of sp. gr. 1·75—1·76, and the mixture is heated on the water-bath for 5—6 minutes. Aconitine is coloured by this treatment at the most only a faint yellow, but if a crystal of pure resorcinol be now added, and the heating continued, a yellowish-red coloration is produced, which gradually becomes stronger, being at its maximum intensity after heating for about 20 minutes. It is stated that no other alkaloid gives this reaction.—A. S.

Linaria vulgaris; Some chemical constituents of ——. Fandre. Rep. Pharm., 1906, **18**, 499.

The extract obtained from the plant with light petroleum spirit contains a saturated hydrocarbon, crystallising from the solvent, almost insoluble in alcohol, m. pt. 57° C. It also contains a phytosterol, crystallising in hexagonal plates, m. pt. 138° C. From the alcoholic extract, mannitol, several sugars (including dextrose), and linarein, have been isolated. The latter is identical with the linaric acid of Schlagdenhauffen and Reeb, but according to the author, it possesses no characters of an acid. It has the formula, $C_{14}H_{16}O_7$; m. pt., 255°—256° C. It is found only in the leaves and flowers. On oxidation, it yields linarodin, $C_9H_{10}O_3$; m. pt. 36·5° C., which is a soluble body with an agreeable odour recalling anise and coumarin. It can be distilled with steam, and has the characters neither of a phenol nor of an aldehyde.—J. O. B.

Terpenes and essential oils. (82*nd communication.*). *Terpinene.* O. Wallach. Annalen, 1906, **350**, 141—179.

Terpinene gives crystalline addition products with the halogen acids, which are liable to be mistaken for the corresponding dipentene derivatives. The hydrochloride, $C_{10}H_{16},2HCl$, melts at 51°—52° C. and boils at 108°—109° C. at 10 mm. The hydrobromide, $C_{10}H_{16},2HBr$, melts at 58°—59° C., and the hydriodide, $C_{10}H_{16},2HI$, at 76° C. These addition products are readily formed by treating sabinene or the terpineol of majoram oil dissolved in acetic acid with a halogen acid. Terpinene bihydrochloride appears to be 1,4-bichlorohexahydro-*p*-cymene. If terpinene bihydrochloride be warmed with aniline, pure terpinene results; this boils at 179°—181°, and has the sp. gr. 0·846 at 20° C., and $n_D = 1·4789$. It has a characteristic odour of lemons, and yields a nitrosite melting at 155° C., and the above-mentioned halogen acid addition products. The author discusses the boiling point and constitutional formula of dipentene. Terpinene bihydrobromide on treatment with silver acetate yields *a*-terpineol. The following substances were obtained by treating the respective halogen terpene compounds with aqueous alkali solution: limonene monohydrochloride gave active *a*-terpineol; dipentene bihydrochloride, m. pt. 50° C., gave dipentone and *a*-terpineol together with *cis*- and *trans*-terpine; *cis*-dipentone bihydrochloride, m. pt. 22° C., gave only *cis*-terpine; terpinene bihydrochloride, m. pt. 52° C., gave γ-terpineol, $C_{10}H_{18}O$, boiling at 212°—214° C., and with sp. gr. 0·0290, together with a new terpine, $C_{10}H_{18}(OH)_2$, which crystallised in leaflets melting at 136·5°—137·5° C. The author describes the behaviour of halogen acids towards *a*-terpineol, *β*-terpineol, γ-terpineol (which yields a mixture of dipentene and terpinene hydrochlorides), *cis*-terpine, and the active terpineols of Ceylon cardamom oil and majoram oil. Dipentene bihydrochloride and terpinene bihydrochloride can be separated from each other owing to the fact that the former is more rapidly acted upon by aqueous alkali. Sabinene yields on treatment with hydrochloric acid in glacial acetic acid, terpinene bihydrochloride with no trace of dipentene derivatives. Sabinene is converted into terpinene by boiling with dilute sulphuric acid. From the results of Kondakow (Chem.-Zeit., 1902, II., 722) it appears that *a*-thujene on treatment with hydrobromic acid yields terpinene bihydrobromide. Ceylon cardamom oil contains a hydrocarbon yielding terpinene bihydrochloride, m. pt. 52° C., terpinene, and a terpineol identical with that contained in majoram oil. The remainder of the paper is taken up with the discussion of this terpineol, terpinene nitrosite, and the constitution of terpinene.—F. Shdn.

Essential oils; Use of artificial esters as adulterants of ——. C. T. Bennett. Chem. and Drug., 1906, **69**, 691.

The author draws attention to the adulteration of French lavender and bergamot oils by ethyl citrate. This substance, when added in small quantities, has little effect on the physical characters of lavender and bergamot oils, but, owing to its high saponification value, will appreciably increase the apparent ester content of the oils. It can be readily detected by chemical analysis. Other esters which might be used for similar purposes of adulteration are alkyl oxalates, tartrates, benzoates, and cinnamates.

—A. S.

Pyramidone; Some microscopic reactions of ——. F. Weehuizen. Pharm. Weekblad, 1906, **43**, 1105—1106. Chem. Centr., 1906, 2, 1628—1629.

The following reactions are described:—

Dilution of pyramidone solution.	Reagent.	Reaction.	After stirring and shaking.	Appearance under microscope.
Faintly acid with sulphuric acid. 1:100	Iodine in potassium iodide	Reddish-brown ppt.	Dirty yellow ppt.	Yelow prisms, with many fine needles.
Faintly acid with sulphuric acid. —	Bromine in potassium bromide.	Green, changing to violet, red, and yellow.	Colour disappears; white ppt.	Colourless, irregular needles, longer and finer than with iodine and potassium iodide.
1:400	Mayer's reagent.	White ppt.	—	Triangular forms.
1:400	Potassium-cadmium iodide.	White ppt.	—	Rosettes of crystals, together with pentagonal and hexagonal leaflets
—	Mercuric chloride.	White ppt.	—	Feathery needles.
—	Sodium-palladium chloride	Yellow ppt.	—	Very fragile yellow needles, occasionally arranged in X- and Y- forms.

—A. S.

Levulinic acid; Iodometric determination of ——. B. Savarè. Gaz. chim. ital., 1906, **36**, [2], 344—348.

THE importance of levulinic acid as a product of the hydrolysis of hexoses, and of the oxidation of terpene alcohols, renders a satisfactory method for the determination of this acid necessary. The author recommends converting the acid into its calcium salt, $(C_5H_7O_3)_2Ca,2H_2O$, and determining this iodometrically by Messinger's method. A solution of the calcium salt is treated with known quantities of $N/10$ iodine solution (in potassium iodide) and $N/1$ potassium hydroxide (in excess). The following reactions occur :—

$$CH_3CO(CH_2)_2COOH + 3I_2 + 5KOH =$$
$$CHI_3 + COOK(CH_2)_2COOK + 3KI + 4H_2O.$$

The precipitated iodoform is filtered off into a Gooch crucible, the solution is treated with a quantity of $N/1$ hydrochloric acid equal to that of potassium hydroxide previously added, and the free iodine is titrated with $N/10$ thiosulphate solution. The iodine combined as calcium iodide and iodate remains unaltered. The number of c.c. of thiosulphate used subtracted from the volume of iodine solution added in the first place gives the number of c.c. of iodine solution consumed, of which each c.c. = 0·0019344 grm. of levulinic acid.—A. S.

Methyl and ethyl alcohols; Preparation of chemically pure ——, *and their specific gravities.* P. Klason and E. Norlin. Arkiv för Kemi, 1906, **2** [3], No. 24. Chem. Centr., 1906, **2**, 1480—1481.

METHYL alcohol was prepared in a purer condition than from methyl oxalate, by dissolving 500 grms. of pure potassium-methyl sulphate in water, adding a little more than the calculated quantity of pure sulphuric acid, making up the solution to about 2 litres, separating the free methyl-sulphuric acid, and distilling methyl alcohol therefrom. Nearly the theoretical amount of methyl alcohol was obtained in the first litre of distillate. The methyl alcohol was concentrated by repeated fractionation, finally after addition of recently ignited potassium carbonate. The last traces of water were removed by repeatedly heating with filings of metallic calcium and distilling. The pure methyl alcohol thus obtained was quite odourless, and was not coloured on heating with an equal volume of sulphuric acid on the water bath. Pure ethyl alcohol was prepared in a similar manner from potassium-ethyl sulphate; it, also, was odourless, and was not coloured on warming with sulphuric acid. The results of the specific gravity determinations were as follow :—For methyl alcohol: sp. gr. at 15°/15° C., 0·796742; referred to water at +4° and *in vacuo*: at 0°, 0·80999; at 10°, 0·80069; at 20°, 0·79134; at 30°C., 0·78184; at $t°$ (between 0° and 30° C.), $0·80999 - 0·00093t - 0·00000025t^2$. For ethyl alcohol: sp. gr. at 15°/15° C., 0·794130; referred to water at +4° and *in vacuo*: at 0°, 0·80628; at 10°, 0·79792; at 20°, 0·78938, and at 30°C., 0·78080. These figures are nearer to those of Winkler (this J., 1905, 1253) than to those of Mendelejeff.—A. S.

Charcoals; Adsorptive properties of various ——. L. Rosenthaler and F. Türk. Arch. Pharm., 1906, **244**, 517—536.

THE authors have studied the adsorption of various pharmaceutical substances from their solutions when treated under standard conditions with different kinds of charcoal. These charcoals may be divided, according to their adsorbent powers, into strongly adsorbent: bone, flesh, and "vegetable blood" charcoals, in the above order; and weakly adsorbent or non-adsorbent: blood, lime-wood, and sponge charcoals. For the same kind of charcoal, the adsorption of any substance varies with the solvent which is employed. The adsorption is by far the strongest in aqueous solutions; it is less with ethyl alcohol, methyl alcohol, ethyl acetate, acetone, and least of all with chloroform solutions. The speed of adsorption depends on the same factors as influence the amount of adsorption, being greatest in the case of bone charcoal and aqueous solutions. The quantity of substance adsorbed by a given quantity of charcoal is relatively less for concentrated solutions than for dilute solutions. All the circumstances which favour adsorption act in a similar degree in resisting the re-extraction of the adsorbed substance. The decolorising power of the charcoal is dependent on its adsorbing power. As regards the use of charcoal for decolorising purposes, the authors state that the charcoal must be carefully purified before use, either by repeated extraction with the solvent which is to be used, or by igniting gently and washing with acid. The quantity of charcoal employed should be as small as possible. It is not necessary to heat the liquid with the charcoal; several hours' contact at the ordinary temperature will suffice. The decolorisation should not, for preference, be effected on an aqueous solution, because the loss of substance by adsorption is at a maximum in that solvent; the solution should be as concentrated as possible. Easily oxidisable substances should not be decolorised by animal charcoal, because this charcoal has a powerful oxidising action; the oxidation of alkaloids is retarded by treating them in the form of salts. Blood charcoal has the strongest oxidising action, lime-wood charcoal has hardly any. Bone and flesh charcoals can be employed in the determination of caffeine without loss of alkaloid, but in the determination of sugars, &c., in wine and other liquids, charcoal should not be used unless it has been proved that no loss by adsorption takes place under the conditions of the experiment. The close interdependence of the decolorising and adsorbent properties of charcoals suggests that the decolorisation is due to adsorption of the colouring matters. The fact that successful results can be obtained in practice depends first on the circumstance that the amount of colouring matter is generally only a fraction of the total substance in solution, and secondly, on a selective adsorption, according to which the quantity adsorbed is generally proportional to the molecular weight, most colouring matters being substances of high molecular weight.

Camphor [in celluloid]; Determination of ——. A. Arnost. XIX., page 1169. C.

Essential oils: U.S. Census of ——. Oil, Paint, and Drug Rep., Oct. 29. [T.R.]

IN 1905 there were 52 establishments engaged in the manufacture of essential oils, having a product of $1,464,652, as compared with 47 establishments having a product of $813,495 in 1900. The principal items of increase were in peppermint and witchhazel oils. The products of the industry by kind, quantity, and value are shown in the following table :—

	1905.	1900.
Products, total value	*$1,464,662	$813,495
Essential oils :—		
Natural oils—peppermint—		
Pounds	130,022	202,550
Value.....	$470,037	$188,559
Sassafras—		
Pounds	30,235	119,131
Value.....	$17,673	$38,165
Wintergreen—		
Pounds	4,737	2,166
Value.....	$15,579	$3,638
Other natural oils—		
Pounds	297,673	518,893
Value.....	$520,648	$470,347
Witchhazel—		
Gallons	797,700	110,260
Value.....	$367,873	$54,649
Artificial oils	$65,250	$52,050
All other products	$7,602	$6,087

* In addition, essential oils to the value of $14,500 were made by establishments engaged primarily in the manufacture of other products.

ENGLISH PATENTS.

Magnesium compounds ; Manufacture of organic ——. A. Zimmermann, London From Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. Eng. Pat. 21,757, Oct. 25, 1905.

ACCORDING to this invention organic magnesium compounds can be obtained in good yields, if a solution of a pinene hydrohalide be allowed to react on metallic magnesium in the presence of a catalytic agent such as iodine or an alkyl- or aryl-halide which renders magnesium active, such as methyl iodide, bromobenzene, benzyl chloride, &c. Ether, benzene, or toluene, or a mixture of ether with a suitable hydrocarbon, is used to dissolve pinene hydrochloride. The following is given as an example of the method of preparation :—To metallic magnesium (1·6 kilos.) a solution of iodobenzene (0·3 kilo.) in dry ether (0·7 kilo.) is gradually added. When the reaction is proceeding briskly, a solution of pinene hydrochloride (2·5 kilos.) in ether (1·8 kilos.) is added, the mixture being kept constantly stirred, and, further, a solution of pinene hydrochloride (7·5 kilos.) in benzene (5 kilos.) is also added. By regulating the supply of the solution, or by cooling the vessel in which the reaction takes place, the temperature is regulated so that it does not exceed 50°—60° C. When the whole solution is added and the product is cool, stirring is continued for one or two hours, during which operation, as during the whole process, moisture, oxygen, &c., must be prevented from reaching the product of the reaction.—G. W. McD.

Organic substances ; Process for the transformation of —— by partial combustion. J. Walter, Geneva, Switzerland. Eng. Pat. 21,941, Oct. 27, 1905. Under Int. Conv., Oct. 27, 1904.

SEE Fr. Pat. 360,785 of 1905 ; this J., 1906, 493.—T. F. B.

Formic acid ; Process for the manufacture of concentrated ——. Chem. Fabr. Grünau, Landshoff und Meyer Akt.-Ges., Grünau, Germany. Eng. Pat. 14,438, June 23, 1906. Under Int. Conv., July 1, 1905.

SEE Fr. Pat. 367,316 of 1906 ; following these.—T. F. B.

FRENCH PATENTS.

Fatty acids ; Production of mono-iodo [and mono-bromo] substitution products from higher ——. Farbenfabr. vorm. F. Bayer und Co., First Addition, dated June 21, 1906, to Fr. Pat. 362,370, Jan. 12, 1906. Under Int. Conv., July 29, 1905.

THE monobromo derivatives of the higher fatty acids form salts with magnesium and the alkaline-earth metals similar to those obtained with the iodo-acids described in the principal patent (this J., 1906, 714). For example, 25 parts of hydrated calcium chloride are dissolved in 120 parts of hot alcohol, ammonia is passed through the solution until precipitation of ammonium chloride ceases, and 130 parts of 92 per cent. alcohol are added. When cool, a solution of 40 parts of monobromobehenic acid (obtained by the action of hydrobromic acid on erucic acid) in 120 parts of alcohol, is added to the mixture ; the precipitated salt is filtered, washed with water until the washings are free from chlorine, and then with alcohol, and finally dried *in vacuo*.—T. F. B.

Formic acid from formates ; Manufacture of concentrated ——. Chem. Fabr. Grünau, Landshoff und Meyer Akt.-Ges. Fr. Pat. 367,316, June 21, 1906. Under Int. Conv., July 1, 1905.

FORMIC acid of a concentration of 97 to 98 per cent. is said to be produced in good yield by heating a formate with an acid salt of a polybasic acid. One part of sodium formate is intimately mixed with two parts of acid sodium sulphate (90 per cent.), and heated in a still, with or without an agitating device ; the residue consists of anhydrous sodium sulphate.—T. F. B.

Camphene ; Production of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 368,170, July 18, 1906. Under Int. Conv., July 20, 1905.

SEE Eng. Pat. 16,429 of 1906 ; this J., 1906, 909.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 1117.)

Plants ; Action of —— on a photographic plate in the dark. W. J. Russell. Roy. Soc. Proc., B, 1906, **78**, 385—390.

THE property possessed by wood of acting on a photographic plate (see this J., 1904, 988; also 1906, 1117), is possessed by leaves, and also by seeds, roots, bulbs, and most vegetable substances. To obtain this action, the leaves must be partially dried, *e.g.*, by pressing between blotting paper. The time necessary for exposure varies from a few minutes to 18 hours, according to the nature and condition of the leaf. The action may be accelerated by heat, but the temperature must not be above 55° C. Fresh leaves are more active than old dried ones, but the activity of the latter may be considerably increased by moistening slightly. It is found that the liquid expressed from leaves and absorbed by blotting paper is also capable of acting on a photographic plate.—T. F. B.

Selenium ; Studies on the sensitiveness of —— to light. P. von Schrott. Phot. Korr., 1906, **43**, 432. Chem.-Zeit., 1906, **30**, Rep. 384.

CRYSTALLINE selenium obtained from potassium selenide is not sensitive to light, nor does it conduct electricity. By warming, it is partially converted into metallic selenium, conductive, and sensitive to light. The red, crystalline variety of selenium, obtained from its solution in carbon bisulphide, is also converted into the metallic condition by heating. The modification obtained by allowing amorphous selenium to remain in contact with quinoline for fourteen days is also sensitive to light. This property disappears at temperatures near the melting point about 210° C.): when cool again, its resistance is found to be increased. The author considers that the increase or decrease of electric conductivity is probably due to ionisation or polymerisation respectively of the selenium.—T. F. B.

ENGLISH PATENTS.

Photographic prints on "self-toning" paper ; Treatment of ——. F. J. Shepherd, East Molesey, and J. J. Griffin and Sons, Ltd., London. Eng. Pat. 5276, March 5, 1906.

PRINTS on "self-toning" papers are immersed, before fixation, for about 10 minutes in a solution of aluminium chloride (about 2 per cent.), and then fixed as usual : the resulting prints are stated to be permanent, and of excellent tone.—T. F. B.

Photographic pigment paper. A. G. Bloxam, London. From Neue Photographische Ges., A.-G., Steglitz, Germany. Eng. Pat. 14,435, June 23, 1906.

French Patents.

Photographic pigment paper. Neue Photographische Ges., Akt.-Ges. Fr. Pat. 367,461, June 26, 1906. Under Int. Conv., Sept. 7, 1905.

Pigment papers have already been prepared with an intermediate film of gelatin or other colloid soluble in hot water, to facilitate the removal of the sensitive pigment film from the support; however, the bichromate solution used for sensitising penetrates into this intermediate film in places, and the latter, becoming partly insoluble, does not altogether fulfil its purpose. This defect is overcome by the present invention, in which the gelatin, &c., of the intermediate film is mixed with some substance which converts bichromates into normal chromates; sodium carbonate is stated to be very suitable, as also are other alkaline compounds, such as magnesium oxide, borax, sodium phosphate, &c. The intermediate film may be prepared, for example, by dissolving 100 grms. of gelatin and 20 grms. of crystallised sodium carbonate in 100 c.c. of hot water.—T. F. B.

Printing from relief plates with a liquid medium; Process of ——. Neue Photographische Ges., A.-G. First Addition, dated June 27, 1906, to Fr. Pat. 362,400, Jan. 13, 1906.

See Eng. Pat. 996 of 1906; this J., 1906, 952.—T. F. B.

Photographic printing; Imps. in ——. T. Manly. Fr. Pat. 368,260, July 21, 1906. Under Int. Conv., Aug. 22, 1905.

English Patents.

Nitrocellulose; Solvents for —— in the preparation of explosives. A. T. Cocking and Kynoch, Ltd., Birmingham. Eng. Pat. 25,081, Dec. 4, 1905.

In gelatinising soluble nitrocellulose with ether-alcohol, the sheets or cords are very liable to curl up or become distorted on leaving the machine, owing to the rapid evaporation of the ether. The use of acetone and amyl acetate for insoluble nitrocellulose and nitroglycerin compounds, is also attended with certain manufacturing difficulties, such as overheating during incorporation, in the case of acetone, and the difficulty of removing amyl acetate on drying, owing to its high boiling point. The invention consists in the use of suitable mixtures of acetone and alcohol as a solvent for nitrocellulose, the proportion of the two ingredients being chosen with regard to the degree of nitration of the nitrocellulose used. The manufacturing difficulties mentioned above are thus avoided. In the manufacture of cordite, Mark 1, a mixture of acetone (60 per cent.) and alcohol (40 per cent.) is used as the equivalent of 100 per cent. of acetone. Cordite MD can be gelatinised with acetone (70 per cent.) and alcohol (30 per cent.). The same proportions are also used for a guncotton containing 10 per cent. of soluble nitrocellulose, whilst a soluble nitrocellulose is gelatinised with a mixed solvent containing acetone (40 per cent.) and alcohol (60 per cent.) It is thus possible, by the use of suitable mixtures of acetone and alcohol, to produce a complete solvent, or partial solvent, for any form of nitrocellulose.

Explosive or gunpowder; Machines for making grains or flakes of ——. C. Dobbs and J. R. Pitman, Haskell, N.J., U.S.A. Eng. Pat. 13,860, June 16, 1906. Under Int. Conv., June 29, 1905.

See Fr. Pat. 367,548 of 1906; following these.—T. F. B.

Powder; Manufacture of ——. C. Claessen, Berlin. Eng. Pat. 16,725, July 24, 1906.

Reduction of the temperature of explosion, and increase of the stability of nitrocellulose and nitroglycerin powders can be obtained by adding to them completely substituted ureas. Diethyldiphenylurea has been found to be particularly suitable for this purpose. These tetrasubstituted ureas present the advantage, as compared with such a substance as camphor, previously used, that they are non-volatile, and constitute advantageous gelatinising media for nitrocellulose.—G. W. McD.

Lead and alloys of lead; Solvent for —— especially suitable for the removal of lead fouling from gun-barrels. Kings Norton Metal Co., Ltd., T. A. Bayliss, H. W. Brownsdon, and H. M. Smith. Eng. Pat. 2506, Feb. 1, 1906. X., page 1153.

Explosives; U.S. Census of ——. Oil, Paint, and Drug Rep., Oct. 29, 1906. [T.R.]

In 1905, 124 establishments, having a product of $29,602,884, were engaged in the manufacture of explosives, as compared with 97, having an output of $17,125,41 in 1900, an increase of 73 per cent. in the value of products. The following table shows the principal materials used by kind, quantity, and value:—

Rockets; Process for the manufacture of ——. J. Stern and S. Molnár. Fr. Pat. 367,537, June 28, 1906.

To minimise the production of sparks in signalling rockets, and increase their luminosity, it is proposed to use coal in the composition, in place of the wood-charcoal usually employed. The following is given as a suitable composition:—Barium nitrate (2 parts), milk sugar (2 parts), coal (5 parts), and potassium chlorate (10 parts).
—G. W. McD.

Powder; Machine for the manufacture of polygonal grains of ——. C. Dobbs and J. R. Pitman. Fr. Pat. 367,548, June 28, 1906. Under Int. Conv., June 29, 1905.

BY means of two feeding cylinders a sheet of explosive is passed over a horizontal knife furnished with teeth of semipolygonal shape, and having a lateral movement backwards and forwards, the width of one tooth. Two rotating knives, with similar shaped teeth, mounted opposite to each other on a spindle, engage with the horizontal knife, and the sheet is thus cut completely into polygonal shaped grains. The accompanying figure represents the arrangement of knives looked at from above. The sheet passes over the horizontal knife, *j*, from left to right. The teeth, *r*, of the rotating knife cut the first half of the grain in contact with the teeth, *k*, of the horizontal knife. When this cut has been completed, the sheet is moved on by the feeding cylinders, the horizontal knife is moved by a crank through the slits, *l*, in the direction, *k*, *r*, the width of one tooth, and the second rotating knife, *q*, cuts the remaining part of the polygonal shaped grain by means of the teeth, *s*.

INORGANIC—QUANTITATIVE.

Copper; Determination of —— by titanium trichloride. E. L. Rhead. Chem. Soc. Trans., 1906, **89**, 1491—1495.

THE method proposed consists in reducing an acid solution of a cupric salt, to which potassium thiocyanate (10—20 c.c of a 10 per cent. solution) has been added, by means of titanium trichloride solution. It is best to preserve the titanium solution in an apparatus with a hydrogen generator attached (see Knecht, this J., 1903, 825). In order to obtain a sharp end reaction, the titration is carried out in presence of a ferrous salt, which may be added to the titanium solution or to the copper solution, preferably to the latter. The ferrous salt is oxidised to the ferric state by the cupric salt, and the end of the titration is indicated by the disappearance of the red colour due to ferric thiocyanate. The titanium chloride solution is prepared by boiling 50 c.c. of a strong solution (commercial 20 per cent.) with 50 c.c. of strong hydrochloric acid, and diluting to 2 litres. It is standardised by ferrous ammonium sulphate (compare Knecht, *loc. cit.*). The presence of ammonium chloride, sodium acetate, zinc sulphate or chloride, ferrous sulphate, and stannic chloride have no influence on the results. Nitric acid must not be present, and if ferric salts are contained in the solution they are determined with the copper, and a correction must be made. The titration should be carried out below 30° C. The results compare favourably with those obtained by the electrolytic and iodide methods.
—A. S.

Mercury; Volumetric determination of ——. E. Rupp. Ber., 1906, **39**, 3702—3704.

MERCURY is precipitated from an alkaline solution by means of formaldehyde, an excess of *N*/10 iodine solution is added to convert the mercury into mercuric iodide, and the excess of iodine is titrated with thiosulphate.

To the mercury solution (containing about 0·2 grm. in 25—50 c.c.) is added 1 grm. of potassium iodide, so that the mercuric iodide formed, goes into solution again. The liquid is made alkaline with caustic soda, and 2—3 c.c. of 40 per cent. pure formaldehyde diluted with 10 c.c. of water are added. After 30—60 secs., the mixture is acidified with acetic acid, and an excess of $N/10$ iodine solution (25 c.c.) introduced. Finally the free iodine is titrated with $N/10$ thiosulphate, using starch as indicator. Although the first stage of the reaction is somewhat modified by the presence of nitric acid, in the case of mercuric nitrate, yet the end product of the reaction is the same. Mercurous salts must first be converted into mercuric salts before treating with formaldehyde. In the case of mercuric cyanide it is advisable to acidify with sulphuric acid instead of acetic acid, when any cyanogen iodide formed decomposes again into cyanogen and free iodine.—B. J. S.

Molybdenum; Determination of ——. J. Darroch and C. A. Meiklejohn. Eng. and Min. J., 1906, **82**, 818.

This is an adaptation of the well-known molybdate method of estimating lead. From 0·5 to 1 grm. of the material, ground to pass a 100-mesh sieve, is fused with 4 grms. of sodium peroxide in a nickel crucible. The assay is kept in a fused state, not above a dull red heat, for three to five minutes, and is then allowed to cool, the crucible being gently rotated during the whole time. After extracting the mass with boiling water, the extract is boiled down to about 150 c.c., filtered, washed, and the filtrate acidified with acetic acid. This acid solution, which should be colourless, is then titrated, boiling, with lead acetate solution (25 grms. per litre), which has been standardised with ammonium molybdate solution, itself standardised in the usual way with lead sulphate. The titration is carried out as in the estimation of lead by the molybdate method, tannic acid being used as indicator. The end point is reached when the brown colour can no longer be obtained with a drop of the solution removed to a plate. If the ore contains much silica and iron, it is better to mix the weighed portion with 3 grms. of sodium peroxide, and add gradually to 10 grms. of fused caustic soda. When completely fused, another 3 grms. of sodium peroxide are cautiously added, and the fusion conducted as before. The method was found to give excellent results with ores and ferro-molybdenum, the complete assay occupying not more than an hour.
—F. Sodn.

Hydrofluosilicic acid; Determination of ——. L. Schucht and W. Möller. Ber., 1906, **39**, 3693—3696.

The method given by Sahlbom and Hinrichsen (this J., 1906, 1068) for the estimation of hydrofluosilicic acid, though accurate, is rather involved. The authors have been working for some years to obtain a method based on simple titration. Titration with alkali, using methyl orange or phenolphthalein as indicator, gave results which varied with the concentration of the solution, owing to hydrolytic decomposition caused by the hydroxyl ions. If an excess of neutral calcium chloride solution be added, however, titration can be carried out in the cold, using methyl orange, the following reaction taking place:—

$$H_2SiF_6 + 3CaCl_2 + 6NaOH = 3CaF_2 + 6NaCl + H_4SiO_4 + 2H_2O.$$

In practice a 4-N calcium chloride solution is used, consistent results being obtained with widely-varying dilutions.—B. J. S.

Dithionic acid and dithionates; Analysis of ——. R. H. Ashley. Amer. J. Science, Silliman, 1906, **22**, 259—262. Chem. Centr., 1906, **2**, 1356—1357.

The method of determination examined by the author consisted in decomposing the dithionate, by heating its solution with hydrochloric or sulphuric acid, driving over the sulphur dioxide into an iodine solution by means of carbon dioxide, and titrating the excess of iodine with thiosulphate. The method gives good results when sulphuric acid is employed, but unsatisfactory ones when hydrochloric acid is used. The author offers the explanation that with sulphuric acid, the liberation of the whole of the dithionic acid is soon complete, as the insoluble barium sulphate produced is removed from the system. Moreover, the solution can be concentrated until white fumes begin to appear, without any appreciable quantity of acid distilling into the iodine solution, whereas when hydrochloric acid is used, some of it passes over, and interferes with the sharpness of the starch reaction. The experiments were made with barium dithionate, prepared by acting with sulphur dioxide on manganese dioxide suspended in water in a vessel cooled by melting ice, adding excess of barium hydroxide solution, filtering, precipitating the excess of baryta from the solution as barium carbonate, and evaporating the filtered solution. The salt has the composition, $BaS_2O_6,2H_2O$. The author was unable to obtain the compound, $BaS_2O_6,4H_2O$, which has been previously described.—A. S.

Chlorine and bromine; Separation of —— in acid solution by hydrogen peroxide. P. Jannasch. Ber., 1906, **39**, 3655—3659.

A method for the quantitative separation of iodine from iodides in presence of bromides and chlorides, by heating with hydrogen peroxide in acetic acid solution, has been previously described (this J., 1906, 199). It is now found that an efficient separation of bromine from bromides in presence of chlorides can be effected in a similar manner by heating with hydrogen peroxide in a solution containing a considerable quantity of free sulphuric acid. The solution (25 c.c.) containing the halogens is heated with a mixture of 25 c.c. of concentrated sulphuric acid, 15 c.c. of water, and 30 c.c. of 6—8 per cent. hydrogen peroxide solution, and the liberated bromine is carried over by a current of carbon dioxide, and absorbed in ammoniacal hydrazine sulphate solution, from which it is subsequently precipitated as silver bromide.—A. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 1123.)

Rare earths; Toxicity and action on fermentations of ——. A. Hébert. Comptes rend., 1906, **143**, 690—693.

Plants were not injured in water containing the sulphates of zirconium, thorium, cerium, and lanthanum, until the concentration reached 5 grms. per litre. Yeast,

diastase, and emulsin were "killed" by the salts of thorium and zirconium even at a concentration of 0·5 grm. per litre, whilst cerium and lanthanum salts appeared to have no action.—J. T. D.

Sucroclastic action of acids as influenced by salts and non-electrolytes. R. J. Caldwell. Proc. Roy. Soc., 1906, **78** A., 272—295. (Compare Armstrong and Caldwell, this J., 1904, 1165.)

STRESS is laid on the need of maintaining the proportions of water and acid as well as that of the hydrolyte, constant throughout experiments of this kind, so that the amount of the added substance is the only variable. The experiments described, the results of which are given in tabular form, show that cane sugar itself and several other carbohydrates have a relatively small though very distinct increasing effect on the rate of inversion of cane sugar by acids; alcohol has a marked inhibiting effect, probably because it enters into competition with the water and withdraws hydrogen chloride from it; glycerol—a non-electrolyte—occupies an intermediate position between alcohol and the carbohydrates, and the weak electrolyte, acetic acid, also has but little influence. Metallic salts accelerate the rate of change, the influence of those derived from monad metals being already considerable, and that of salts derived from dyads at least twice as great. This activity is due to their dehydrating influence. To ascertain the "degree of hydration" of the salt, the extent to which it was necessary to dilute the weight-normal solution in order to reduce the value of the constant K to 510—the standard value—was determined in each case. The values arrived at were as follows, the figures indicating mols. of water per mol. of the salt: ammonium chloride, 10; potassium chloride, 10; sodium chloride, 13; barium chloride, 19; and calcium chloride, 22. Tables are also given to show the influence of various carbohydrates on the electrolytic conductivity of solutions of hydrogen chloride and sulphuric acid.—E. F. A.

Colloids; Separation of —— by filtration. Bechhold. Z. Chem. und Ind. der Kolloide, 1906, **1**, 107—108.

THE now accepted fact that colloidal solutions are of the nature of suspensions rather than solutions proper, entails the supposition that colloidal particles can be separated from their "solvent" by means of suitable filters. The author has succeeded in preparing such filters by impregnating bases of vegetable fibre or wire gauze with gelatinous materials of varying concentration. Filtration is carried out in a specially designed apparatus at pressures of 0·2 to 4 atmospheres. In this way pure "solvent" may be withdrawn from colloidal solutions of arsenic sulphide, ferric hydroxide, egg-albumin, hæmoglobin, and globulin. Jellies of different concentration act as filters of different permeability; thus it was found possible to separate mixtures of colloidal silver and hæmoglobin, and to fractionate mixtures of peptone-albumoses. Enzymes and toxins have a tendency, not shared by ordinary albuminoids, to combine with, or "dye," the filtering material.—W. A. C.

Colloids; Contribution to the chemistry of ——. K. Winkelblech. Z. angew. Chem., 1906, **19**, 1953—1955.

WHEN a solution of gelatin is vigorously shaken with benzine (petroleum spirit), some of the colloid is precipitated as a stiff emulsion of gelatin, benzine, water, and air. With very dilute solutions the result is a permanent whitish ring of exceedingly small bubbles, settling around the walls of the vessel. This reaction is very delicate, serving to detect a few mgrms. of gelatin per litre. It is best carried out with quantities of 10 c.c. in a vessel of the diameter of an ordinary test-tube. Slight acidity of the solution is favourable, but in presence of much acid, alkali, or salt, the test must be performed on larger quantities. It is found that petroleum, melted paraffin, benzene, chloroform, and carbon bisulphide may also be used. Solutions of other colloids, both organic and inorganic, give the reaction. Tannin reacts, but gallic acid does not. Conversely, solutions of fats in hydrocarbons give similar permanent layers of emulsion with water or (better) dilute alkaline or acid liquids.—W. A. C.

Trade Report.

U.S. CUSTOMS DECISIONS; RECENT ——.

Bd. of Trade J.

Following is a *resumé* of some recent decisions given by the Board of General Appraisers:—

Articles.	Paragraph of the Tariff under which dutiable.	Rate of Duty.
Casein, as an albumen not specially provided for, or as lactarene	468 or 594	Free.
Semolino, a by-product in the manufacture of wheat flour, used as a farinaceous food, and for making puddings, &c., as an unenumerated manufactured article	Section 6	20 % *ad val.*
Printing paper.—A thin, flimsy coloured paper said to be used for "printing circulars and printing of all kinds," but not shown to be suitable for books or newspapers, dutiable as paper not specially provided for	402	25 % „
Zinc white paint, or enamel white paint, containing zinc, but not containing lead, ground in oil and reduced to liquid form by the addition of varnish and turpentine, and thus ready for use as a liquid paint, is not dutiable as "zinc, oxide of, and white paint or pigment, containing zinc, but not containing lead, . . . ground in oil;" but is dutiable as paint, not otherwise specially provided for	58	30 % „
Ripolins.—Paints or colours, known as ripolins are subject to the same rate of duty, under the same provision	do.	do.
Wood charcoal produced by a burning process by which every characteristic of wood is eliminated is not dutiable as a manufacture of wood, but as a non-enumerated manufactured article	Section 6	20 % „
Chemical glassware.—Articles composed exclusively of blown glassware in the form of flasks, &c., designed for use in chemical laboratories ..	100	60 % „
Articles designed for similar use but composed of moulded or pressed glass or of blown glass in combination with parts of moulded glass or other material	112	45 % „
Woulff bottles, or flasks (both terms interchangeably applying to the same article)	99	Various rates according to capacity.

German Chemical Industry.

Chem. Trade J., Nov. 17, 1906.

The report of the Association for the Protection of the Interests of the Chemical Industry of Germany refers to the development which took place during 1905, and to the profitable nature of the chemical undertakings as revealed by the reports of a number of companies. The Association has drawn upon the returns issued by 142 companies, with an ordinary share capital of £23,000,000, and bonds and mortgages totalling £4,200,000, while the reserve funds stand at £7,100,000. These companies paid, for 1905, £3,475,000 in dividends and as bond and mortgage interest, being an average of 10·12 per cent. as compared with 9·52 per cent. in 1904. If, however, only the average dividends distributed in recent years are compared with one another, and the most prosperous year hitherto (1899) be taken as a unit at 100, the ratios work out as follows for the past few years:—1899, 100; 1900, 91·1; 1901, 90·9; 1902, 87·8; 1903, 93·3; 1904, 97·7; and 1905, 106·2. It will thus be seen that the year 1905 has eclipsed 1899, which was the record year of the last period of prosperity. It is assumed that the present year will not exhibit any material change in the favourable development of the German chemical industry, notwithstanding the operation of commercial treaties disadvantageous to the export trade of the country.

New Books.

Savons et Bougies. Paul Puget, Ing. Chimiste E.C.P., Prof. à l'Ecole Superieure de Commerce de Nantes. Librairie J. B. Baillière et Fils, Rue Hautefeuille, 19. Paris. 1907. Price 5 frs.

Small 8vo volume, containing 382 pages of subject matter, and an alphabetical index. The text is illustrated with 79 engravings, and treats of the following subjects:—Soaps. I. Fatty Matters. II. Soaps and Candles. III. Decomposition of neutral fatty matters. IV. Glycerin. V. Hard Soaps. VI. Soft Soaps. VII. Toilet Soaps. VIII. Soaps for Industrial, Medicinal, and Veterinary application. IX. Soap Analysis. Candles. I. General considerations. II. Stearic and Palmitic Acids. III. Tallow Melting. IV. Separation of Solid from Liquid Fatty Acids. V. Manufacture and Analysis of Candles.

Contribution a l'Etude de la Saponification des Corps Gras. Par M. Maurice Nicloux, D.ès.Sc., M.D. Librairie Scient. A. Hermann, Rue de la Sorbonne, 6, Paris. 1906. Price 3 frs.

Pamphlet, 8vo size, containing 73 pages of subject matter, and a table of contents. The subject is treated under the following heads:—I. Introduction. II. Historical. III. Extraction of the active substance of the seed of the Castor Oil plant—the cytoplasm. IV. Dissociation of the Cellular Constituents. V. Cytoplasm and grains of Aleuron. VI. Measure of Activity. VII. Study of the Hydrolysing properties of the isolated Cytoplasm. VIII. Are the active powers, specially the Hydrolysing power of the Cytoplasm, not due to the presence of a soluble ferment? IX. Application of the preceding experimental results to the study of some points in Vegetable Physiology. XII. Detailed study of Saponification. XIII. General conclusions.

Outlines of Qualitative Chemical Analysis. By Frank Austin Gooch and Philip Embury Browning, Professor and Assistant Professor of Chemistry in Yale University. John Wiley & Sons, New York. 1906. Chapman & Hall, Ltd., London. Price 5*s.* 6*d.*

8vo volume, containing 139 pages of subject matter, and an alphabetical index. The subject matter is comprised under:—I. Introductory. II. The Basic Analysis. III. Acidic Analysis. IV. The Systematic Examination. V. Organic Compounds.

Ice Formation, with Special Reference to Anchor-Ice and Frazil. By Howard T. Barnes, M.A.Sc., D.Sc., &c., Associate Professor of Physics, McGill University, Montreal. John Wiley & Sons, New York. 1906. Chapman & Hall, Ltd., London. Price 12*s.* 6*d.*

8vo volume, contains 250 pages of subject matter with 39 illustrations and a chart with sectional plans. There is also an alphabetical index. The subject matter is treated under the following heads:—Introduction: I. Physical Laws governing the Transfer of Heat. II. Physical Constants of Ice. III. Formation and Structure of Ice. IV. Sheet, Frazil, and Anchor Ice. V. Precise Temperature Measurements. VI. River Temperatures. VII. Theories to account for Frazil and Anchor-Ice. VIII. Methods of overcoming the Ice Problem in Engineering Work.

Ferric and Heliographic Processes. A Handbook for Photographers, Draughtsmen, and Sun Printers. By George E. Brown. Dawbarn & Ward, Ltd., 6, Farringdon Avenue, London, E.C., 1906. Price 2*s.* net.

Small 8vo volume, containing 126 pages of subject matter, two pages of bibliography, and an alphabetical index. There are 17 illustrations. The subject matter treats of the following items:—I. The Ferroprussiate Process. II Toning Blue prints and their Uses. III. Ferroprussiate in Tri-colour Work. IV. Kallitype Process. V. Obernetter Process. VI. Uranotype Process. VII. Prints on Fabrics—Prints in Dyes. VIII. Heliographic Processes compared. IX. Preparation of Heliographic Papers. X. Marking Tracings for Sun Copying. XI. Outfit for Heliographic Printing. XII. Ferroprussiate, or White Line on Blue Ground. XIII. Pellet, or Blue line on White Ground. XIV. Ferrogallic, or Black Line on White Ground. XV. Brown Line on White Ground. XVI. Minor Heliographic Processes. XVII. Paper and Sizing. XVIII. Chemicals.

Practical Radiography. A Handbook of the Applications of the X-Rays, with many Illustrations. By A. W. Isenthal and H. Snowden Ward. Second Edition. Dawbarn & Ward, Ltd., 6, Farringdon Avenue, London, E.C. 1898. Price 2*s.* 6*d.* net.

8vo volume, with 157 pages of subject matter and 68 illustrations. The matter is classified under the following heads:—1. Practical Radiography.—Historical. II. Apparatus. III Electrical. IV. Photographical. V. Medical. VI. Diagnostical Applications. VIII. Therapeutic Value of the X-Rays. VIII. General Applications and Probabilities. IX. Theory of the X-Rays.

Paper Technology: An Elementary Manual on the Manufacture, Physical Qualities, and Chemical Constituents of Paper and of Paper-making Fibres. By R. W. Sindall, Technical Adviser to the Government of India. Chas. Griffin & Company, Ltd., Exeter Street, Strand, London. 1906. Price 12*s.* 6*d.* net.

8vo volume, containing 247 pages of subject matter, and an alphabetical index. The text is illustrated with a frontispiece, 13 plates, and 158 illustrations. The subject matter is classified under the following heads:—I. Introduction. II. Technical Difficulties relating to Paper. III. Rag papers. IV. Esparto; Straw; Notes on Beating. V. Wood Pulp. VI. Wood Pulp Papers. VII. Packing Paper. VIII. "Art" Papers. IX. The Physical Qualities of Paper. X. Chemical Constituents of Paper. XI. The Microscope. XII. Fibrous Materials used in Paper-making. XIII. Analysis of a Sheet of Paper XIV The C.B.S. Units. XV. Cellulose and its Derivatives. XVI. History, Chronology, and Statistics. XVII Dictionary of Technical Terms. XVIII. Glossary of various Papers, with brief notes as to origin of same, and use of the Papers. XIX. Questions on "Paper Manufacture" set by the City and Guilds of London Institute, 1902—1906.

JOURNAL OF THE

Society of Chemical Industry.

No. 25.—Vol. XXV. SUPPLEMENT. DECEMBER 31, 1906.

HON. TREASURER:—
Samuel Hall, East London Soap Works, Bow, E.

PRESIDENT:—
Eustace Carey.

GENERAL SECRETARY:—
Charles G. Cresswell.

EDITOR:—
Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

OFFICES:—
Telegraphic Address: "59 *Palatable, London.*" 59, Palace Chambers, Westminster, S.W. *Telephone No:* "715, *Victoria.*"

Journal and Patent Literature.

Class.	Page.
I.—General Plant, Apparatus and Machinery	1209
II.—Fuel, Gas, and Light	1209
III.—Destructive Distillation, Tar Products, Petroleum, and Mineral Waxes	1212
IV.—Colouring Matters and Dyestuffs	1213
V.—Preparing, Bleaching, Dyeing, Printing and Finishing Textiles, Yarns, and Fibres	1215
VI.—Colouring Wood, Paper, Leather, &c.	1218
VII.—Acids, Alkalis, and Salts, and Non-Metallic Elements	1219
VIII.—Glass, Pottery, and Enamels	1220
IX.—Building Materials, Clays, Mortars, and Cements	1221
X.—Metallurgy	1221
XI.—Electro-Chemistry and Electro-Metallurgy	1224
XII.—Fatty Oils, Fats, Waxes, and Soaps	1226
XIII.—Pigments and Paints; Resins, Varnishes, &c.; India-Rubber, &c.	1226
XIV.—Tanning; Leather; Glue, Size, Bone, and Horn; Ivory and Substitutes	1227
XV.—Manures, &c.	1227
XVI.—Sugar, Starch, Gum, &c.	1227
XVII.—Brewing, Wines, Spirits, &c.	1228
XVIII.—Foods; Sanitation; Water Purification; and Disinfectants	1229
XIX.—Paper, Pasteboard, Cellulose, Celluloid, &c.	1231
XX.—Fine Chemicals, Alkaloids, Essential Oils, and Extracts	1231
XXI.—Photographic Materials and Processes	1232
XXII.—Explosives, Matches, &c.	1232
XXIII.—Analytical Chemistry	1233
XXIV.—Scientific and Technical Notes	1233

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8*d.* each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the By-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this By-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896—1905.

IMPORTANT NOTICE.

The Hon. Treasurer is prepared to receive subscriptions for the Decennial Index (1896—1905). The Authors' Names portion is now in the press and will be issued early in the new year; and the subject-matter portion will follow as soon as possible afterwards. The price is 10*s.* for the whole Index, or 11*s.* ($2.75) post free.

Copies of the Collective Index (1881—1895) may be had at the same price.

Cheques on members' own bankers, or money orders, payable at the G.P.O., London, should be made payable to Samuel Hall, and sent to the Hon. Treasurer, East London Soap Works, Bow, E., with the signed fly-leaf of a notice which will be sent out with the ordinary subscription notice, and to any others who make application for it.

SUBSCRIPTIONS OF MEMBERS ABROAD.

IMPORTANT NOTICE.

Members are reminded that the subscription of 25*s.* ($6.15) for 1907 should be sent so as to reach the Hon. Treasurer early in the New Year, so as to ensure continuity in the receipt of the Society's Journal.

For the greater convenience of members abroad, arrangements have been made whereby cheques on their own bankers, drawn in the usual way and in their own currency, will be accepted in payment of subscriptions. Cheques and money orders on G.P.O., London, should be made payable to Samuel Hall, and forwarded to him at Bow.

The return, whenever possible, of the fly-leaf attached to the subscription notice, is specially recommended as a means whereby the sender may be identified, and changes of address recorded, on which depends the safe receipt of the Journal.

"INDUSTRIAL DISEASES COMMITTEE."

With reference to a notice which appeared in the November 15th issue of the JOURNAL (p. 1062), announcing the appointment of a Departmental Committee "to inquire and report what diseases and injuries, other than injuries by accident, are due to industrial occupations, are distinguishable as such, and can properly be added to the diseases enumerated in the Third Schedule of the Workmen's Compensation Bill, 1906," members who desire to assist the Committee by tendering evidence are requested to communicate with the Society.

List of Members Elected.

Dec. 21, 1906.

Bancroft, John, Wilmington, Del., U.S.A., Bleacher and Dyer.

Barbour, R. B., Eclipse Chemical Manufacturing Co., Chelmsford, Mass., U.S.A., Manager.

Blyth, M. Wynter, 36, Eastcheap, London, E.C., Analytical and Consulting Chemist.

Boutwell, Arthur T., Smith and Dove Manufacturing Co., Andover, Mass., U.S.A., Superintendent of Bleaching and Dyeing.

Casaburi, Dr. Vittorio, Ford Morocco Co., Wilmington, Del., U.S.A., Leather Chemist.

Davies, Harry R., 74, India Street, Boston, Mass., U.S.A., Chemist.
Dillon, Frederick N., 16, Prospect Street, Fitchburg, Mass., U.S.A., Engineer.
Duncalfe, Roger, Forge Mills, Bestwood Colliery, Nottingham, Glue Manufacturer.
Dunford, J. H., Trent Side Bone Works, Nottingham, Assistant Manager.
Futers, Stephen H., Glenraven House, Heol-y-Fai, Maesteg, Glamorgan, Analyst.
Grasser, N. H., Argold Hall, Llangollen, North Wales, Manufacturing Chemist.
Grocnewoud, S. H., 36, Grosvenor Road, Highbury, London, N., Analytical Chemist.
Hoseason, J. H., Sun Buildings, Bridge Street, Manchester, Chemical Manufacturer.
Huyett, M. C., 1203, Traders' Bank Building, Toronto, Canada, Mechanical Engineer.
Inglis, Dr. J. K. H., University College, Reading, Lecturer.
Johnson, Dr. Harold, 5 and 6, Fowkes Buildings, Great Tower Street, London, E.C., Chemist.
Kinnersley, H. W., 25, Bourne Hall Road, Bushey, Herts, Chemist and Manufacturer.
Lacell, H. G., Marlowes, Hendon Lane, Finchley, N., Chemist.
Lowe, James, City Chambers, 45, John Street, Glasgow, Assistant Engineer, Gas Department.
Lowe, Jos. A., Fitchburg, Mass., U.S.A., Paper Manufacturer.
Lowson, William, The University, Leeds, Assistant Chemical Lecturer.
Marsden, Oliver, Manor Road Mill, Victoria Road, Leeds, Cashier.
Mihalovitch, S. F., 514, E. Pearl Street, Cincinnati, Ohio, U.S.A., Chemist.
Morson, Thomas Pierre, 14, Elm Street, Gray's Inn Road, London, W.C., Chemical Manufacturer.
Neil, Dr. Archibald A., 82, Eccles Old Road, Manchester, Chemical Engineer.
Parker, Elias G., 238, Grafton Avenue, Newark, N.J., U.S.A., Chemist.
Peirce, Edwin H., American Telephone and Telegraph Co., 125, Milk Street, Boston, Mass., U.S.A., Chemist.
Perrow, Mosby G., Lynchburg, Va., U.S.A.
Pincott, E. S., 222, St. James' Street, Montreal, Canada, Manager, Nichols Chemical Co.
Potter, Dr. Henry Noel, c/o Sawyer Mann Co., 523, W. 23rd Street, New York City, U.S.A., Electrical Engineer.
Pudney, Sydney H., 156, Bellwood Avenue, Toronto, Canada, Foreman.
Schramm, Quirin, Otto-Hilgenstock Coke Oven Co., Ltd., Tingley, near Wakefield, Chief Chemist.
Shankland, Geo. A., Millthorpe, Watson Avenue, Mansfield, Company Manager.
Shepard, Jas. H., Chemical Agricultural Experiment Station, Brookings, S. Dak., U.S.A., Chemist.
Slack, Edwin B., 39, Huron Street, Toronto, Canada, Chemist.
Smith, Dr. G. McP., Chemical Laboratory, University of Illinois, Urbana, Ill., U.S.A., Instructor in Chemistry.
Steers, Thornton, 229, Grand Avenue, Brooklyn, N.Y., U.S.A., Chemist.
Tattersfield, Fredk., The Hollins, Dewsbury, Yorks, Analyst.
Travell, N. E., Wright's Finishing Co., Ltd., Great Freeman Street, Nottingham, Lace Dresser.
Wardlaw, Thos. D., c/o The Geigy Aniline and Extract Co., 60, Front Street West, Toronto, Canada, Canadian Manager.
Wenger, Francis E., Helvetia, Newcastle, Staffs., Ceramic Colour Manufacturer.
Williams, A. Ll. Griffith, Uzina Consanceõ de Sinimbu, S. Miguel dos Campos, Maceio, Brazil, Sugar Planter.
Wilson, J. Murray, c/o Hamilton Powder Co., Belœil Factory, near Montreal, Canada, Technical Chemist.
Wynne, Prof. W. Palmer, F.R.S., The University, Sheffield, Professor of Chemistry.
Yerkes, Leonard Augustus, c/o Jos. Bancroft and Sons Co., Wilmington, Del., U.S.A., Cotton Bleacher and Finisher.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the Journal depends.

Bayly, F. W., l/o Sydney, N.S.W.; retain Journals.
Beckers, Dr. W., l/o Stone Street; 128, Duane Street, New York City, U.S.A.
Brown, Walter B.; all communications to Victor Chemical Works, 89, Board of Trade Buildings, Chicago. Chemist and General Superintendent.
Diestel, Wm., l/o William Street; 128, Duane Street, New York City, U.S.A.
Dow, Allan W., l/o Washington; 73, Upper Mountain Avenue, Montclair, N.J., U.S.A.
Escher, Paul, l/o Chicago; c/o Smith, Emery and Co., 1068, Broadway, Oakland, Cal., U.S.A.
Forbes, Eli, l/o Lancaster Mills; Clinton, Mass., U.S.A.
Gref, A., l/o Stone Street; 128, Duane Street, New York City, U.S.A.
Hadfield, R. A.; Hecla Works, Sheffield; 28, Hertford Street, Mayfair, London, W.; and (Journals) Parkhead House, Sheffield.
Hays, B. F., l/o Brooklyn; c/o E. R. Squibb and Sons, 80, Beekman Street, New York City, U.S.A.
Hibbeler, C., l/o Somerville; 1, Ellsworth Park, Cambridge, Mass., U.S.A.
Hinchley, J. W., l/o Bangkok; 15, Fawcett Street, London, S.W.
Hogben, Walter; Journals to 9, Duddingston Crescent, Portobello, Edinburgh.
Humel, E. J.; l/o Clark Avenue; 7912, Grace Avenue, S.W., Cleveland, Ohio, U.S.A.
Hyde, Austin T., l/o Box 365; P.O. Box 98, Rumford Falls, Maine, U.S.A.
Imrie, John, l/o Milton; 415, Shields Road, Glasgow.
Jenks, R. L.; Journals to Central Excise Laboratory, Kasauli, Punjab, India.
Keppelmann, A. J., l/o Box 1549; P.O. Box 1382, Philadelphia, Pa., U.S.A.
Kitamura, Y., l/o Tokyo; Kaigun Kōshō, Yokosuka, Japan.
Labonde, Dr. L.; All communications to 145, West Adams Street, Los Angeles, Cal., U.S.A.
Macmillan, A., l/o Sunderland; Seaforth House, Blackhall, Mid-Lothian.
McDowall, Wm., l/o Taltal; c/o Inglis, Lomax and Co., Antofogasta, Chili.
Miller, H. Harold, l/o McMasters Avenue; 303, Front Street East, Toronto, Canada.
Muckenfuss, A. M.; all communications to c/o University of Mississippi, University, Miss., U.S.A., State Chemist.
Muter, Dr. John; Journals to 325, Kennington Road, London, S.E.
Muurling, L. J. R., l/o Box 2160; P.O. Box 1935, New York City, U.S.A.
Nishigawa, T., l/o Osaka; 12, Yamamoto Dori, Nishome, Kobe, Japan.
Pease, F. N., l/o New York; P.O. Box 503, Altoona, Pa., U.S.A.
Persons, A. C., l/o Prospect Street; 74, Oak Street, Willimantic, Conn., U.S.A.
Propach, C., l/o North Clark Street; 224, Randolph Street, Chicago, Ill., U.S.A.
Ridsdale, C. H., l/o Ferndale; Ravenscroft, Roman Road, Linthorpe.
Smoot, Albert M., l/o Elizabeth; 99, John Street, New York City, U.S.A.
Spoor, J. L.; all communications to Rede Court, Rochester, Kent.

Stevens, T. R. B., l/o Merton: retain Journals.
Tsukiyama, S., l/o Osaka; 2nd of No. 2116, Fukiaichō, Kobe, Japan.
Tutton, H. R., l/o Gravesend; 12, Ivy Street, Penarth, South Wales.
Weiss, P., jun., l/o Wharton; Vulcanite Portland Cement Co., Phillipsburg, N.J., U.S.A.
Williams, Percy, l/o Clapton; (subscriptions) 75, Fairfax Road, London, N.W., and (Journals) c/o A. J. Simons, Pontianak, Dutch West Borneo, *via* Singapore.
Wilson, L. P., l/o Wallasey; Boston House, Stoney Stanton Road, Coventry.
Woodman, Dr. Durand, l/o Pearl Street; 80, Beaver Street, New York City, U.S.A.
Worstall, R. A., l/o Church Street; 726, Clinton Place, Evanston, Ill., U.S.A.

Change of Address Required.

Flammer, E., l/o Heilbronn a/Neckar, Germany.

Change of Style and Address.

King, Lieut. A. E.; all communications to King, Capt. A. E., R.A., Inspector of Explosives, Egyptian Army, Citadel, Cairo, Egypt.

Deaths.

Bernays, Joseph, l/o 96, Newgate Street, London, E.C. Dec. 24.
Blass, Edward, Essen (Ruhr), Germany.
Cabot, Samuel, 141, Milk Street, Boston, Mass., U.S.A. Nov. 26.
Potts, Jos. T., Price's Patent Candle Co., Bromborough Pool, Dec. 11.

Patent List.

N.B.—In these lists [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 27,552. James. Method of making liquid air and other liquid gases. Dec. 4.
" 27,592. Crush. Filter frame and process of filtration.* Dec. 4.
" 27,621. Martin and Rideal. Apparatus for heating Dec. 4.
" 27,691. Hellström. Centrifugal liquid separators. [Swed. Appl., Dec. 9, 1905.]* Dec. 5.
" 27,776. Kunick (Kunick). Continuous removal or introduction of substances from or into chambers standing under vacuum. Dec. 6.
[A.] 27,807. Radcliffe. *See under* XVII.
" 27,824. Thom. *See under* XII
" 27,900. Guy. Kilns and ovens fired with producer and other gases. Dec. 8.
" 28,225. Chmelewski. Kilns.* Dec. 11.
" 28,555. Watel and Harper. Apparatus for mixing or diluting solutions. Dec. 14.
" 28,574. Thwaite and Defries. High temperature gas furnace. Dec. 14.
[C.S.] 25,404 (1905). Schröder. Manufacture of homogeneous products from liquids or liquefied substances. Dec. 19.
" 25,570 (1905). Trotman and Hackford. Apparatus for automatically recording the temperature of ovens, dyeing vats, &c., and for controlling the supply of fuel to a steam generator, or the steam supply therefrom. Dec. 19.
" 4547 (1906). Cartwright. Surface apparatus for condensing, evaporating, or the like. Dec. 12.
" 15,516 (1906). Siehert. Smoke consuming furnace. Dec. 19.
" 16,583 (1906). Prollius. Centrifugal drums or apparatus. Dec. 12.

II.—FUEL, GAS, AND LIGHT.

[A.] 27,459. Johnson and Willis. Permeated electric arc lamp carbons and incandescent lamp filaments. Dec. 3.
" 27,540. Douglas. Suction gas producers. Dec. 4.
" 27,842. Forbes. Preparing carbide of calcium for generators. Dec. 6.
" 27,908. Grafton. Removal of naphthalene from illuminating gas. Dec. 7.
" 27,943. Mallison. Production of methane or gases containing it Dec. 7.
" 27,967. Ickringill and Hellwell. Incandescent mantles. Dec. 8.
" 28,038. Lake (Cone). Generation of gas.* Dec. 8.
" 28,086. Sclater. Suction gas apparatus. Dec. 10.
" 28,148. Bachman. Apparatus for washing gases.* Dec. 10.
" 28,181. Crossley and Rigby. Manufacture of producer gas. Dec. 11.
" 28,269. Wilton. Recovery of sulphur from gases, and purification of coal gas. Dec. 11.
" 28,274. McKay. Compressed, cemented coke leavings. Dec. 12.
" 28,281. Hatfield. Arc lamp electrodes. Dec. 12.
" 28,475. Robertson and Graham. Production of fuel and coke. Dec. 13.
" 28,576. Buss and Fohr. Making briquettes of coal, peat, &c.* Dec. 14.
" 28,580. Woodall and Duckham. Vertical retorts for the destructive distillation of coal.* Dec. 14.
" 28,660. Kurzer. Drums for gasifying heavy carburetted oils. [Ger. Appl., Aug. 24, 1905.* Dec 15.
[C.S.] 24,940 (1905). Ladd. Gas furnaces. Dec. 12.
" 24,949 (1905). Lake (Deuts. Gasglühlicht A.-G.). Incandescing bodies or mantles for gas lighting. Dec. 12.
" 25,313 (1905). Atkinson. Suction gas producers. Dec. 12.
" 25,574 (1905). Simpson. Removal of sulphur and other impurities from coke. Dec. 19.
" 25,596 (1905). Lake (Selas Gas.). Manufacture of a mixture of gas and air for illuminating purposes. Dec. 19.
" 26,829 (1905). Fielding. Suction gas generators. Dec. 12.

[C.S.] 27,002 (1905). Bloxam (Lux). Manufacture of electric incandescent lamp filaments from tungsten or molybdenum or an alloy thereof. Dec. 19.

„ 753 (1906). Thompson (Wurts). *See under* III.

„ 1980 (1906). Morton. Producer gas plants. Dec. 14.

„ 4119 (1906). Ingrey, Bartlett and Maclure. Production of acetylene and other gases. Dec. 12.

„ 9020 (1906). Bloxam (Lux). Manufacture of filaments of tungsten or molybdenum for electric incandescence lamps. Dec. 19.

„ 18,485 (1906). Allgem. Elektricitäts Ges. Incandescing bodies for electric lighting and heating. Dec. 12.

„ 22,049 (1906). Weigel and Wolf. Steam and gas generators. Dec. 12.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 27,945. Cowper-Coles. Production of petroleum compounds with low flashing points. Dec. 7.

„ 28,014. Claussen. Enriching light mineral oils or hydrocarbons. [Belg. Appl., Dec. 13, 1905.]* Dec. 8.

„ 28,089. Soc. Anon. des Combustibles Industrielles. Distillation of hydrocarbons. [Fr. Appl., April 19, 1906.]* Dec. 15.

[C.S.] 753 (1906). Thompson (Wurts). Distilling coals and other hydrocarbonaceous substances. Dec. 12.

„ 9202 (1906). Carter and Newell. Oils for lubricating purposes. Dec. 19.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 28,139. Johnson (Badische Anilin und Soda Fabrik). Manufacture of compounds or colouring matters of the anthracene series. Dec. 10.

„ 28,240. Johnson (Badische Anilin und Soda Fabrik). Manufacture of compounds and colouring matters containing sulphur. Dec. 11.

„ 28,578. Badische Anilin und Soda Fabrik. Manufacture of vat colouring matters containing sulphur. [Ger. Appl., Jan. 22, 1906.]* Dec. 14.

[C.S.] 8490 (1906). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of new monoazo dyestuffs. Dec. 19.

„ 9695 (1906). Newton (Bayer und Co.). Manufacture of new disazo dyestuffs and intermediate products. Dec. 12.

„ 10,866 (1906). Newton (Bayer und Co.). Manufacture of new derivatives of the anthracene series. Dec. 19.

„ 16,100 (1906). Kalle und Co. Manufacture of sulphur-containing red colouring matter. Dec. 19.

„ 16,101 (1906). Kalle und Co. Manufacture of sulphur-containing red colouring matter. Dec. 19.

„ 16,907 (1906). Kalle und Co. Manufacture of thioindoxylcarboxylic acid. Dec. 19.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 27,438. Sagar. Apparatus for mercerising and sizing fibrous material. Dec. 3.

27,447. Pickles and Pickles. Finishing textile fabrics. Dec. 3.

[A.] 27,527. Kunstfäden Ges.m.b.H. Manufacture of artificial silk filaments for nitrocellulose. [Ger. Appl., Dec. 4, 1905.]* Dec. 3.

„ 27,727. Friedrich. Manufacture of artificial threads, films, or the like. [Ger. Appl., Dec. 11, 1905.]* Dec. 5.

„ 27,904. Clare. Sizing yarns, warps, and cloth. Dec. 7.

„ 28,271. Diedrichs. Apparatus for washing, bleaching, and dyeing textile fibres, spun yarns and textile fabrics. Dec. 11.

„ 28,317. Pike and Hough. Rollers for calico printing, &c. Dec. 12.

„ 28,533. Knowles and Yates. Apparatus for use in bleaching, dyeing, mercerising, and like treatment of yarn or threads. Dec. 14.

„ 28,711. Védie. Dyeing. Dec. 15.

[C.S.] 25,537 (1905). British Algin Co., Ingham and Bunzl. Treatment of textiles, paper, &c., with compounds of alginic acid. Dec. 19.

„ 25,681 (1905). Baudot. Treatment of raw wool. Dec. 19.

„ 2083 (1906). Hey. Treating textile fibrous material with products of electrolysis of water solutions of acids, oxides, and salts. Dec. 19.

„ 7574 (1906). Haddan and Co., and Buxton. Finishing pile fabrics. Dec. 12.

„ 9432 (1906). Severen. Manufacture of horsehair filaments. Dec. 12.

„ 11,254 (1906). Hausdorf. Apparatus for treating fabrics with liquids. Dec. 19.

„ 11,351 (1906). Schäfer. Fireproof material. Dec. 12.

„ 13,752 (1906). Puchert and Puchert. Cleaning wool fibre. Dec. 19.

„ 16,088 (1906). Thiele and Linkmeyer. Production of artificial silk. Dec. 19.

„ 17,660 (1906) Schmitt and Handschin. Dyeing and bleaching apparatus. Dec. 19.

„ 20,519 (1906). Miller. Mercerising apparatus. Dec. 12.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 27,828. Roth. Utilising in an advantageous manner the nitrogen of the air in the form of nitride.* Dec. 6.

JAMESTOWN EXPOSITION: SPECIAL ALCOHOL EXHIBIT.

An exposition is to be held at Jamestown, Va., U.S.A., from April 26th to Nov. 30th, 1907, to celebrate the 300th anniversary of the first English settlement on North American soil. A special feature will be an exhibit of the various apparatuses, machines, and appliances by which the heat, light, and power which can be obtained from alcohol may be utilised for domestic, agricultural, and manufacturing purposes, and also of the articles of manufacture into which alcohol enters as a component or factor. The exhibit will be under the superintendence of Prof. Charles E. Munroe, of George Washington University, to whom all applications for space should be addressed.

SECRET COMMISSIONS AND BRIBERY PREVENTION LEAGUE.

A league for the prevention of secret commissions and bribery has been formed under the auspices of the London Chamber of Commerce. Among the objects of the League are to expose flagrant cases of bribery, corruption, and blackmail, and, if necessary, to take steps to prosecute; and also to assist its members and subscribers in any action which may be considered by the Council necessary to recover secret commissions paid or received. All communications should be addressed to the Secretary, Mr. A. E. W. Gwyn, 58, Coleman Street, London, E.C.

Deaths.

Bernays, Joseph, 1/o 96, Newgate Street, London, E.C. Dec. 24.

Blass, Edward, Essen (Ruhr), Germany.

Cabot, Samuel, 141, Milk Street, Boston, Mass., U.S.A. Nov. 26.

Potts, Jos. T., Price's Patent Candle Co., Bromborough Pool, Dec. 11.

Canadian Section.

Meeting held at Toronto, on Thursday, October 25, 1906.

PROF. W. H. ELLIS IN THE CHAIR.

A PAPER on "Industrial Alcohol and its Uses" was read by Dr. W. P. COHOE, and a number of the members took part in the discussion thereon.

Sir WILLIAM PERKIN, who was the guest of the evening, was then introduced by the Chairman, and gave the meeting an account of his discovery of mauve in 1856, and of the obstacles which had to be overcome before it could be produced on a manufacturing scale (see this J., 1906, 759). (See also pages 1207–8.)

THE DETERIORATING EFFECT OF "ACID PICKLE" ON STEEL RODS, AND THEIR PARTIAL RESTORATION ON "BAKING."

BY HERBERT A. BAKER AND W. B. LANG.

IT is the universal practice in wire manufacture to "pickle" the steel rods in order to remove the black scale of oxide before drawing them into wire. This has long been known to deteriorate the quality of the rods, but it has been found that, if the rods are "baked" at 250° F. for some hours after this treatment, they are in a great measure restored, and can then be drawn into wire. The following physical tests were made in order to find out quantitatively the amount of such deterioration and subsequent restoration of the rods. The work was done on samples taken in the different stages of the process of manufacture at the Imperial Steel and Wire Company's plant at Collingwood, Ontario, at the suggestion of the manager, Mr. J. A. Currie. Samples of three different coils of rods were taken in the following stages:—(1) Before treatment with acid; (2) after acid cleaning; (3) after rusting; (4) after lime coating; (5) after baking. Table I. shows the tensile strength, percentage elongation over 8 ins., and percentage contraction of the rods; the strength of the bath, time immersed, and time of baking are also given:—

TABLE I.

	Strength in lb. per sq. in.			Elongation over 8 ins			Percentage contraction.		
Rod	A	B	C	A	B	C	A	B	C
				per cent	per cent	per cent.	per cent.	per cent.	per cent.
Before treatment	65,700	59,700	69,100	16	13	12	63	66	67
After acid cleaning	61,400	59,700	64,200	16	13	13	38	44	47
„ rusting	62,800	57,000	64,700	17	14	11	38	47	44
„ lime coating	65,700	59,700	67,000	16	14	—	37	47	41
„ baking	65,700	58,000	67,600	16	13	—	57	66	56

The strengths of acid used, at 100° C., were: A, 38 per cent; B, 11 per cent.; and C, 10 per cent.; and the times of immersion in the baths: A, 1 hr.; B, 45 mins.; C, 1 hr 10 mins. All the rods remained in the "baker" for about 4 hours.

The tests were made with a Riehlé machine, by the kind permission and with the assistance of the staff in the Engineering Department, University of Toronto. It may be observed that the ultimate strength remains throughout the process as constant as can be expected of that kind of test. The percentage elongation over 8 ins. rather unexpectedly remains constant, but the sudden drop in the ability to contract to a small "neck," before breaking, occurs immediately after acid treatment, and remains practically constant until after "baking," when a marked recovery in this property occurs, the three rods agreeing well in this behaviour. It is important to note that on this property of "necking in," or contracting in area on stretching, depends the property of drawing well through the die, which is a conical hole in a block of tungsten steel.

This deterioration and recovery at the same stages in the process is also well shown in the following bending tests, which corroborate the contraction tests:—

TABLE II.

Bending tests on the rods.

	Before treatment.	After acid cleaning.	After rusting.	After lime coating.	After baking.
Rod A.	100	70	64	64	100
„ B.	100	60	56	57	99
„ C.	100	71	55	53	100

These figures are relative, of course, and express the ability to bend a certain number of times through a definite angle before breaking. They are the result of averaging eight or ten tests in each case. The highest

number was taken as 100, and the rest calculated proportionately. The results show a break in the bending properties of the rod immediately after acid treatment, and a recovery after "baking," thus corresponding to the effect on the rods as indicated by the contraction tests.

Shearing tests were also made, but the differences were so small that no conclusions could be drawn from them.

An examination of the wires of different diameters drawn from these rods (correspondingly marked A, B, C) was also made in the same manner:—

TABLE III.

Tensile strength and percentage contraction of wires.

1. *Tensile strength.*

		Wires A.	Wires B.	Wires C.
	Diam. in.	lb. per sq. in.	lb. per sq. in	lb. per sq. in
(*a*)	0·175	72,900	93,700	93,700
(*b*)	0·142	112,600	113,600	113,900
(*c*)	0·112	117,300	122,400	122,400
(*d*)	0·091	—	138,400	131,000
(*e*)	0·072	137,000	150,000	150,000

2. *Percentage contraction.*

		per cent.	per cent.	per cent.
(*a*)	0·175	52·0	54	47
(*b*)	0·142	45·0	38	36
(*c*)	0·112	28·5	31	32
(*d*)	0·091	—	36	33
(*e*)	0·072	20·0	37	30

It will be observed that wires B and C have a higher tensile strength than wire A. Incidentally the increase of tensile strength on drawing out will be observed. The fall in contraction area percentage, as the diameter of the wires tested decreases, is not so great in B and C as it is in A. This means that these wires could probably be drawn through two more dies before annealing would be necessary, while wire A would, in all likelihood, stand no more drawing. Thus B and C appear to be the better wires. The only difference in the treatment of the rods was that rod A was cleaned in 38 per cent. sulphuric acid, while rods B and C were cleaned in 10 per cent. acid. They were all "baked" about four hours—longer than usual—and are probably restored as much as possible. The results indicate that strong acid causes an unnecessary amount of deterioration in the rod, and that only weaker acid should be employed.

Table IV. gives the comparative bending abilities of the wires: this also would indicate that wires B and C are the better.

TABLE IV.

Bending tests on the wires.

		Wire A.	Wire B.	Wire C.
	Diam. in.			
(*a*)	0·175	91	100	100
(*b*)	0·142	90	97	100
(*c*)	0·112	89	100	83
(*d*)	0·091	—	100	80
(*e*)	0·072	86	100	94

Many superintendents of plants have attributed the deterioration to the presence of sulphur, knowing that sulphur renders steel "cold short." This appears to the authors to be highly improbable, as careful analyses show no difference in the sulphur content, which was 0·051 per cent. both before and after treatment. It seems much more probable that a "hydride" of iron is formed, as has often been suggested. Several tests confirmatory of this idea were obtained, but not sufficiently conclusive for present publication. The investigation is being continued.

London Section.

Meeting held at Burlington House, on Monday, November 5, 1906.

MR. R. J. FRISWELL IN THE CHAIR.

The CHAIRMAN announced that the Committee had elected Dr. Lewkowitsch to the position of Vice-Chairman.

Before calling on Sir William Ramsay to give his discourse he had, at the request of the Committee, to appeal to the members to endeavour to increase the membership of the London Section.

THE ADVANTAGES OF INVESTIGATING THE UNLIKELY.

BY SIR WILLIAM RAMSAY, K.C.B., F.R.S.

I have been asked to give an address to the members of the London Section to-night—I will not call it a paper. One of the luxuries in which I can only too seldom indulge is to say something not for publication, and you have gratified my wish in this. But you have laid on me the injunction to talk to the members of the Section from my personal experience; and this must excuse my egotism. For you will have noticed, gentlemen, the already too frequent use of the first personal pronoun singular.

"De minimis non curat—lex." I suppose this is true: lawyers say so. What I am here to do is to try to convince you that science and industry *should* attend to trifles. It is possible, I suppose, in real life to judge what are trifles and what are not; I am not convinced that it always is. But in science it is not so easy. And yet—a man who studies the markings on a butterfly's wing, or counts the bristles on the antennæ of a bee surely cannot be doing anything very important; but I am judging of a science not ours, and of one of which I know next to nothing. Such markings, however, may have led a Darwin or a Wallace to propound the theory of natural selection; and the bristles may be the organs of a sense unknown to us by means of which the bee gains impressions from some form of radiant energy incapable of impressing our grosser or differing sense-organs. No, I fancy there are no negligibles in Nature.

> "Flower in the crannied wall,
> I pluck you out of the crannies,
> Hold you here, root and all in my hand,
> Little flower—but if I could understand
> What you are, root and all, and all in all,
> I should know what God and man is."

It would be easy to illustrate this theme by instances taken from the work of others: work which in its final form has revolutionised science and industry. I should like to quote the much-quoted instance of Faraday, when he withdrew a magnet out of a coil of wire, and observed that a current flowed during the withdrawal. Think what that simple experiment has taught us of the nature and method of the action of electricity, and of its relationship to magnetic strain; and think too of the wonderful development of this simple deed: how myriads of dynamos are transmitting energy over thousands of miles of wire—energy which furnishes us with light, with power, and which may some day be utilised for distributing heat over our cities!

No tale about my own attempts can compare in interest with such a fairy tale of science; but I shall obey the Chairman's behest and tell you what there is to tell.

(The author then gave a sketch of the discovery of argon, helium, neon, krypton, and xenon, and of the spontaneous change of the emanation from radium into helium; these subjects are treated in full in "Gases of the Atmosphere," 2nd Ed., Macmillan & Co., 1905.)

The lecturer concluded as follows:

These, gentlemen, are the results of some of my investi-

gations of the "unlikely." It was improbable that air should be found to contain five overlooked elements; and perhaps still more improbable that a new gas should be evolved in quantity on heating certain well-known minerals. The acme of unlikeliness was, however, reached when it was proved that a gas, continuously being evolved from compounds of radium, itself spontaneously changed partially into helium. It suggests that it is worth while looking for similar changes in other forms of matter, and points towards universal "degradation" of the elements to the lowest members of their periodic columns. I have been engaged in that research for about two years.

As to the advantages of such investigations, it is hardly necessary to expound them to an audience such as this. First of all, it satisfies the curiosity which all members of the human race possess, or at least should possess—the curiosity to taste of the tree of knowledge. Next, it correlates knowledge; by supplying missing links, it increases the value of what is known; and lastly, it shows that more is sometimes gained by speculative chemistry—trying for results against long odds than in slowly and laboriously accumulating results which could have been foretold.

Dr. DIVERS expressed the opinion that Sir William Ramsay's lecture would be valuable in print in order to place it in the hands of those aspiring to success in chemical research, as an illustration of its methods.

Following some general remarks, Mr. TYRER said, "If we cannot believe a little bit in what we do not see, it is perfectly certain we shall not get very much out of what we may see."

Mr. LEON GASTER pointed out that the neon vacuum tube shown had been made use of by Prof. Fleming in his Cantor Lectures. It could be used as a very sensitive detector of the distribution of potential of stationary waves, by the variation of its glow. When moved in space and brought next to anode of potential, it did not glow, but when held near a loop of potential it glowed brightly. With the aid of the neon tube, the practical application of the cymometer (wave meter) for measurement of long electric waves was demonstrated. This was an instance to show how the unexpected might turn out to be very useful.

Mr. J. C. RICHARDSON asked if Sir William Ramsay could say anything about the later discoveries of Professor Rutherford's with regard to the absorption of the rarer gases by means of cocoa-nut charcoal. There was a letter from Sir James Dewar in "Nature" recently, and the previous week from Professor Rutherford, from which it appeared that the radio-active material from radium was absorbed by cocoanut charcoal.

The CHAIRMAN said some 30 years ago he was assistant to Sir Norman Lockyer, and had many times observed the D 3 line in the chromosphere of the sun. For a long time they were unsuccessfully engaged in endeavouring to discover helium in various minerals, amongst others in the Lenarto meteorite which fell in Sicily about the year 1860. This lecture has shown how the unsuccessful attempts of older workers are gradually corrected, and presently out of apparent chaos order ensues. With regard to the question of the investigation of the unlikely technologists may learn a great deal, because they are continually meeting with small difficulties which, in the hurry of manufacturing operations, are put aside, but all of which more or less deserve investigation. Sometimes, of course, these matters are investigated. The successful working of Lightfoot's black was traced to the aniline salts used on copper rollers for printing on the cloth, entering into the reaction and causing the production of that colouring matter, the most permanent cotton black known until the last few years. Again, within recent years there was the dispute about the preparation of rhodamine, when it turned out that one of the reasons for the success of a particular patented process was because the material of the autoclave neutralised the hydrochloric acid of the so-called anisoline hydrochloride and allowed the methylation to take place. When an enamelled autoclave was used the reaction failed. That explained a direct conflict of evidence on the part of distinguished investigators before a court of justice.

Sir WILLIAM RAMSAY said if it had not been for Dr. Travers and his efficient aid, he thought the last part of the work would not have been done so satisfactorily as it was. After all, the most important discovery—scientific or technical—is to discover an efficient assistant.

All the gases of the atmosphere are absorbed in charcoal, helium least and xenon most. Of course the emanation will also be absorbed, being an easily condensible gas; as Sir James Dewar had pointed out, it ought to be as absorbable as carbon dioxide. Their boiling points do not differ very much. It is curious that Professor Rutherford should have written what he did; it was obviously an oversight. There was no reason why these gases should not condense, and as a matter of fact they all did do so; helium less easily than hydrogen, being more volatile. The condensation of helium is very slight, but neon is fairly easily condensed; indeed this gas remains in the charcoal at atmospheric temperature to a considerable extent, and requires a high temperature before it can all be pumped out. Of course with increase of atomic weight, and consequent increase of density, the absorption by charcoal becomes greater and greater. He should be quite prepared to hear that the emanation could be easily absorbed and retained by charcoal, so that by leaving air containing the emanation over charcoal, it is as certain that the emanation would be absorbed as it is that carbon dioxide would be absorbed under similar circumstances.

In conclusion he should like to elaborate his last sentence a little. "We are a sporting race. There are two ways of working. You can either do what is already done—you can earn your daily bread, get in your money, save it and do a day's work in a day, and so be content. Or you can speculate. These two courses have their analogies in chemistry. You can either follow the regular routine and prepare organic compounds, each new one of which is so like the last that its properties and behaviour can be predicted. Occasionally an interesting compound turns up; interesting because it differs from what might have been expected. Though there are some giants, for example, Prof. Emil Fischer of Berlin, the average man is content to do little bits of work of this nature and is quite happy. On the other hand, it is possible to give a hostage to fortune, as it were—to try something that is not very probable. Some people like to do ordinary routine work: some, on the contrary, like to tempt Providence. I am one of those who prefer the latter course, and I venture to think that Providence has recompensed me to some extent."

Meeting held at Burlington House, on Monday, Dec. 3, 1906.

DR. J. LEWKOWITSCH IN THE CHAIR.

THE DIRECT ESTIMATION OF ANTIMONY.

BY HERBERT W. ROWELL.

The extensive use of antimony alloys makes their analysis a matter of importance to the chemist and metallurgist, and any improvement upon the tedious separation of antimony by the gravimetric process is worthy of consideration. The method to be described, which depends upon the oxidation of antimonious to antimonic chloride by potassium bromate in hydrochloric acid solution, according to the equation

$$KBrO_3 + 3SbCl_3 + 6HCl = 3SbCl_5 + KBr + 3H_2O$$

was first suggested by Győry and modified by Nissenson and Siedler (Chem.-Zeit., 1903, **27**, 749; this J., 1903, 967) for testing hard leads. After many trials their process was modified to the method following:—

The sample to be tested should be in as fine a state of division as possible. Samples of alloys should, if possible, first be cast into thin, narrow bars, so that they may solidify with a minimum amount of "piping," for large ingots, slowly solidified, give a "piping" which often differs considerably from the rest of the ingot. Alloys

are conveniently sampled with a fine hack-saw, and the sawings rejected which do not pass a 30-mesh sieve.

Samples of antimonial lead.	Taken from	Antimony.
		per cent.
Small bar quickly solidified	Outside of bar	10·80
" " " "	"Piping" (very slight)	10·80
1 cwt. bar slowly solidified	Outside of bar	7·50
" " " "	"Piping"	7·79
Small bar filed completely	Filings through 60 mesh sieve	7·89
" " " "	Filings through 30 and on 60 mesh	7·89
" " " "	Filings left on 30 mesh	7·89
Alloy Z in sawings from thin bar	Sawings through 30 mesh	9·42
Alloy Z in sawings from thin bar	Sawings left on 30 mesh	9·42

Standard arsenious chloride solution.—0·8236 grm. of pure powdered arsenious oxide, dried carefully at 100° C., is weighed into a 500 c.c. graduated flask. About 5 c.c. of 10 per cent. sodium hydroxide solution are added, and the flask shaken and gently warmed until the arsenic is completely dissolved; 5 c.c. of strong hydrochloric acid are added and the solution made up to the mark with water. Fifty c.c. of this solution, equivalent to 0·10 grm. of antimony, are measured off with a pipette, the delivery of which has been checked against the 500 c.c. flask. A solution made in this way and kept in a well-stoppered bottle remains unchanged for a fortnight without oxidation.

The indicator.—0·1 grm. of pure methyl orange is dissolved in 100 c.c. of hot water. Drops of this indicator should be taken out with a tube to avoid the stain left about the neck of the bottle, as this or an old solution is liable to leave a stain and spoil the sharp finish. Methyl Blue and other methyl colours stable in hydrochloric acid generally stain the solution, while indigo turns green toward the finish, and the end is not so easily distinguished as with methyl orange. More of a solution of indigo is also required to produce a sufficient colour, which makes the test a trifle higher.

The standard potassium bromate solution is approximately *N*/20, and is made by dissolving 1·41 grms. of the "pure" salt in 1 litre of water. The theoretical quantity is 1·3926 grms. per litre, but the "pure" salt always contains bromide, which, however, makes no difference to the test. To standardise the solution, 20 c.c. of strong hydrochloride acid are added to 50 c.c. of the standard arsenic solution, and the mixture just brought to the boil. Thirty c.c. of the bromate solution are then added, and the titration is finished in exactly the same way as in the method below, observing all the precautions. The solution should be standardised every week, as it loses value at the rate of about 2·5 c.c. per litre per week.

A one-fifth normal solution may be used for titrating larger quantities of antimony.

Bromine solution.—Thirty-five c.c. of pure bromine, thoroughly shaken up with 250 c.c. of strong hydrochloric acid, makes a saturated solution, and leaves excess of bromine. The required quantity is conveniently measured by dipping in a pipette without any stem below the bulb and so allowing it to fill.

Method of analysis.—One grm. of ore or alloy, containing not more than 0·15 grm. of antimony, is weighed off into a 500 c.c. Bohemian beaker. These quantities may be varied, providing that more of the substance can be conveniently dissolved, and that the amount of standard bromate solution required is within the compass of the burette used. To the sample, 25 c.c. of concentrated hydrochloric acid and 5 c.c. of the saturated solution of bromine in hydrochloric acid are added; the covered beaker is then placed on a warm iron plate, so that the temperature is not high enough to drive off the bromine before complete solution is effected, and occasionally shaken until complete solution takes place.

Antimony oxides, and precipitates of mixed oxides of antimony and tin which do not dissolve readily in this way, may be fused with eight times their weight of caustic soda in a silver crucible at a dull red heat, till the mass turns yellowish-green. The fused mass is dissolved in as little water as possible, and transferred to a 500 c.c. beaker, and the solution acidified with hydrochloric acid and evaporated down to 10 c.c., when 20 c.c. of hydrochloric acid are added. To reduce the antimony, 3 or 4 grms. of fresh sodium sulphite crystals are added, the cover and sides of the beaker lightly rinsed down with water, and the liquid evaporated, with the cover on, to 10 c.c., or a little less if possible. Although there seems to be little risk of the antimony oxidising during the evaporation, the cover is better kept on, as it retards the evaporation very little, and often saves a test when it, or one near to it, spirts through evaporating too far.

Sodium sulphite is better than sulphurous acid for effecting the reduction, as it raises the boiling point considerably towards the finish, and ensures complete volatilisation of the arsenic. If more than 2 or 3 per cent. of arsenic is present, 20 c.c. of strong hydrochloric acid and 5 c.c. of saturated sulphurous acid are added, and the liquid boiled down again.

To the concentrated solution, 20 c.c. of strong hydrochloric acid and 40 c.c. of hot water are added, the cover and sides of the beaker are rinsed, and the whole is boiled for one minute to remove traces of sulphurous acid. The standard solution of potassium bromate is now run in to within a few c.c. of the necessary amount, with constant and thorough stirring, and at the rate of 30 c.c. at most every 50 seconds. If lead chloride begins to crystallise, the solution must be boiled again, but otherwise two drops of Methyl Orange solution are added, and bromate run in drop by drop till the colour of the indicator is destroyed. The solution should be at a minimum temperature of 60°C., and should be kept thoroughly stirred during the titration so that a local excess of bromate never forms, otherwise some of its value is lost before attacking the antimony. The result is calculated from the equation

$$\frac{(\text{c.c. of bromate required by 1 grm. sample—blank})\,10}{\text{c.c. of bromate required by 50 c.c. of arsenic solution.}} = \%\ \text{Sb}$$

A blank test should be made occasionally in exactly the same way as above, omitting the sample, and the result—which should not exceed 0·2 c.c.—subtracted from each test.

Possible sources of error.—The most probable sources of error are the incomplete removal of arsenic or sulphur dioxide.

Oxidation need not be feared if the cover is kept on. The liquid must not be allowed to evaporate to dryness, as antimonious chloride begins to volatilise at about 195°C., and boils at 220°C.

Lead, zinc, tin, silver, chromium, and sulphuric acid have no effect upon the test, but large quantities of calcium and ammonium salts tend to make the result too high.

Iron tends to make the results high, but not in as great a ratio as copper. Iron is very slightly reduced by sulphurous acid in a strong hydrochloric acid solution, and if, before adding the sodium sulphite to a test, it is boiled down to as small a volume as possible and made up again with cold, strong hydrochloric acid, the effect of iron is almost destroyed. With this precaution, 1 per cent. of iron raises the test about 0·02 per cent., while 5 per cent. has very little more effect.

The effect of copper.—Copper is partially reduced by sulphurous acid in a strong hydrochloric acid solution, and, under the conditions of the method given, raises the test in a fairly constant ratio as shown by the following figures:—

	Grm. Sb
0·001 grm. copper as cupric chloride in a blank test	= 0·0001
0·005 " " " " "	= 0·0005
0·010 " " " " "	= 0·0012

Alloy Z	9·42	% Sb.
+0·1 % of copper as cupric chloride	9·45	"
+0·3 " " " "	9·48	"
+0·5 " " " "	9·51	"
+0·8 " " " "	9·51	"
+0·9 " " " "	9·55	"
+1·0 " " " "	9·55	"
+2·0 " " " "	9·75	"
+5·0 " " " "	10·37	"

The quickest and most satisfactory method of obviating the effect of copper is to dissolve the substance in 15 c.c. of nitric acid 1:2, evaporate just to dryness, and boil for a few minutes with 50 c.c. of 1 per cent. nitric acid; allow to settle and pour off the liquid through a fine filter. Add 30 c.c. of 5 per cent. solution of ammonium nitrate, boil again, and transfer all the precipitate to the filter, wash two or three times with a hot 5 per cent. solution of ammonium nitrate, and dry the filter and precipitate. Separate the latter from the filter and fuse it and the filter ash together as directed above. Alloy Z contained 9·42 per cent. of antimony; when 5 per cent. of copper was added and separated as above two determinations gave percentages of 9·40 and 9·37.

Perhaps as exact a way when the copper amounts to about 1 per cent. is to subtract 0·012 per cent. of antimony for every 0·1 per cent. of copper, the copper being estimated by a separate colorimetric test.

The efficiency of the method.—An estimation of antimony in an antimonial lead can be carried out in one hour from the time of weighing. Over 200 estimations have been made in connection with this paper, and the following typical examples show the accuracy of the method:—

	Per cent.
Alloy Z—	
(Commercial lead and antimony), highest test (one)	9·45
(Commercial lead and antimony), lowest test (two)	9·39
(Commercial lead and antimony), average of 22 tests	9·42
Average of four tests, gravimetric, weighed as Sb_2S_3	9·37
Alloy A—	
(Lead, arsenic, antimony), four tests, bromate method	8·65
(Lead, arsenic, antimony), two tests, gravimetric as Sb_2S_3	8·70
Specimen of well-formed stibnite (traces Fe and As)	71·20, 71·35
,, prepared Sb_2S_3	71·40, 71·35
Theoretical value of Sb_2S_3	71·42

Discussion.

Mr. Benedict Kitto said most people had experienced difficulty in getting exact results in the analysis of antimony alloys and ores, further, most of the processes in use were long and tedious, and required great care. He should have much interest in trying the author's process. If it was possible to carry out an antimony assay in an hour or an hour and a half with accuracy, it would be a great advantage.

Mr. T. C. Cloud said this paper was of value, inasmuch as a rapid method of determining antimony in lead was described, which, to mineralogists interested in lead, was a great consideration. If it was possible to make an estimation in one and a half hours or even two hours, lead chemists would be extremely gratified. He was sure many of them would try the process and see if it was really all the author claimed for it.

Mr. A. Philip said that since 1889 he had used the process first devised by Herroun in 1885 for the volumetric determination of antimony. This consisted in dissolving the alloy in hydrochloric acid with potassium chlorate, and, after removing all free chlorine, adding potassium iodide and titrating with thiosulphate as in the iodide process for copper. An allowance for any copper present was made by determining that metal colorimetrically. The presence of iron, however, seriously interfered. The method adopted for sampling the alloy was similar to that described by the author, a hack saw being used to obtain finely divided particles, but in order to obtain homogeneous samples, the alloy as received was melted under paraffin wax or heavy petroleum oil, and then cooled suddenly by pouring on to a large slab of iron. In ordinary work the time taken for making a determination by Herroun's process was longer than that which the author claimed for the process he described, but, including the correction for copper, it was certainly under two hours. It was not clear whether the time of one hour stated to be necessary for the new process included the time required for the removal of the copper and iron. The limits of accuracy in the new process also appeared to be higher than in the Herroun's process, in which, under usual laboratory conditions, an accuracy of about 0·2 to 0·3 per cent. on an alloy of about 10 to 12 per cent. antimony was readily obtainable. This lower degree of accuracy was, however, quite satisfactory for practical purposes when dealing with commercial white metals and anti-friction alloys.

Mr. T. B. McGhie referred to the iodine process recently devised by Dr. John Clark. There was no doubt that method was susceptible of great accuracy, and at the same time was very speedy. The ordinary impurities which occurred in type-metal alloys and anti-friction metals appeared to exercise very little prejudicial effect on the author's process, and he thought it very remarkable that copper should have so slight an influence.

Mr. W. F. Reid said he did not understand why the samples were sifted. He would have thought that the finer and coarse portions had different compositions. He had met that difficulty himself, and found a good way was to use a number of fret saws fixed side by side. The filings so obtained were practically identical in size and of similar composition.

Mr. A. C. Chapman referred to a method recently described for the separation of arsenic from antimony and some other metals by driving it off as methyl arsenious ester; good results were said to be obtained. He would suggest that the author should try if it would suffice to remove 1 to 3 per cent. of arsenic from antimony and tin, as, if so, it might shorten his process to some extent.

Mr. Rowell, in reply, said the samples should be in a fine state of division so as to rapidly effect solution; if the particles were large, considerable time was occupied in dissolving them, which had to be done at a low temperature. He had found the same fault as Mr. Reid with some alloys. On the average, the sawings through a 30-inch sieve never varied from those left on the sieve, but those through a 60-inch mesh might vary if there was a "piping" in the sample. That was why the 30-inch sieve was used, which was as large as was compatible with speed. The effect of the iron was greater when reduction took place in more dilute solutions. If 2 to 3 per cent. of arsenic were present, it was necessary to boil down with a little more sulphurous acid, which might take another 15 or 20 minutes. He tried every other method before settling on this process, including modifications of the iodine process, and could never get satisfactory results. The extreme difficulty of estimating antimony gravimetrically was generally admitted. There were many chances of losing antimony and for including other elements in the final precipitate. There was possible loss of antimony oxide soluble in the nitric acid solutions, and antimony sulphide soluble in sulphuretted hydrogen solutions; there was possible incomplete separation of tin and arsenic and incomplete separation of lead and copper soluble in alkaline sulphantimonate solutions, and in cases where the sulphide was converted into the trioxide, sulphur was invariably included. He frequently met with differences of 1 to 1½ per cent. on the same sample tested by several different chemists. The method he had described was not free from difficulty, but he believed it would be found to be a great deal better than any other in use. In the hands of an ordinary laboratory assistant the analyses ought to be within 0·1 per cent. of the correct result.

THE STANDARDISATION OF DISINFECTANTS.

BY M. WYNTER BLYTH, B.A. (CANTAB.), B.SC. (LOND.), F.I.C.

It is difficult to arrive at any just or even approximate estimate of the amount of chemical disinfectants used in this or any other country. Some slight idea of what vast

quantities must be consumed in the course of each year may be gathered from the fact that, as calculated from statistics kindly supplied to me by medical officers of health, a low estimate would place the amount used for municipal work in English towns in the engineers' departments alone at 10 galls. of liquid disinfectants and 300 lb. of solid disinfectants per 1,000 people; by adding to this the quantities used by Government Departments, hospitals, public and private institutions and by private individuals, one can readily realise that the production, distribution, and application of disinfectants must concern a large industry.

Whether the free use of disinfectants could largely and with advantage be dispensed with, is a question which does not come into the scope of this paper. There is, however, no doubt that the judicious use of good chemical disinfectants is a great and valuable means of fighting disease, while on the other hand the use of worthless disinfectants is a public danger. On this account it is essential that we should have a reliable method for estimating the value of all substances used as germicides.

In the course of time the substances used as disinfectants have tended to become more and more complicated. Chemists have vied with one another in attempting to mix the most varied substances in the hope of producing the perfect disinfectant, until a point has been reached where the analytical chemist finds himself practically defeated and unable to determine, in many cases, the constituent parts of the mixture—and it avails him little in those cases where he is successful, for the germicidal properties of a mixed disinfectant depend quite as much on the method of mixing as on the substances mixed. Chemical analysis is, therefore, in the majority of cases out of the question, and is in no way necessary, since as disinfectants are intended for the destruction of the germs of specific diseases, it has long been recognised that the only satisfactory method of judging the value of a substance which is to be used for this purpose is by measuring the actual quantity that is required to kill some given organism under certain fixed conditions. It must be clearly understood that in this paper I am only dealing with disinfectants as germicides, and that the question of the standardisation of disinfectants as germicides has nothing whatever to do with poisonous, oxidising, deodorising or any other property.

Bacteriologists have in the past determined the actions of a variety of disinfectants on a great variety of micro-organisms, but owing to the use by different observers of different methods, different organisms, and different standards of comparison, the most extraordinary discrepancies as to the relative values of disinfectants may be found in the literature on the subject. To take a concrete example of the different estimates which may be formed of a disinfectant by competent observers, let me quote the case of the disinfectant I will call "A." One observer says "a dilution of 1:150 acting for five minutes on *B. coli* kills the organisms, while 1:20 carbolic is required to kill the same *B. coli* with certainty." These results indicate that "A" is about 7·5 times more efficient than is phenol, or, to put the matter in the modern form, "A" has a carbolic acid coefficient of 7·5. Another observer finds that a dilution of 1:1000 of the same disinfectant, "A," kills *B. typhosus* in 10 minutes, while 1:200 phenol is required to kill the same organism in the same time. These results are equivalent to a co-efficient of about 40. Yet another observer, experimenting with typhoid excreta, gives results which would appear to place the coefficient of this disinfectant at from 60 to 30, according to the time of contact. More recently the coefficient of "A," as determined by the drop method using *B. prodigiosus*, has been placed at only 0·2. I myself have found working by the drop method with *B. coli*, a coefficient of 0·25. So there is a choice of from 0·2 to 60 for the value of a disinfectant, and these discrepancies cannot be wholly explained by the fact that *B. typhosus*, *coli*, and *prodigiosus* were used, since the resistance of these organisms to disinfectants, although not identical, is somewhat similar. They can, however, possibly be explained by the fact that the organisms were grown in different ways, and the methods of working were different in each case. Similar cases of widely different results may be found recorded for almost every well-known disinfectant. These discrepancies had long been apparent, and several suggestions were made from time to time as to more uniform methods of working; but it was left to Dr. S. Rideal and Mr. Ainslie Walker to make the first definite practical proposal as to a standard method of determining the efficiency of disinfectants.

Their method of working is as follows (J. Roy. San. Inst., **24** [111] Oct. 1903). "To 5 c.c. of a particular dilution of the disinfectant in sterilised water add five drops of a 24-hour blood-heat culture of the organism in broth; shake and take sub-cultures every 2½ minutes up to 15 minutes. Incubate these sub-cultures for at least 48 hours at 38° C." "The strength or efficiency of the disinfectant is expressed in multiples of carbolic acid performing the same work—*i.e.*, when we have obtained a dilution of the disfectant which does the same work as the standard carbolic acid dilution, we divide the former by the latter and so obtain a ratio which we call the carbolic acid coefficient." They further recommended a temperature during medication of from 15° to 18° C., and a reaction of + 15 for the standard broth

This method, as may be seen, is the familiar drop method used, I believe, first by Mr. A. Wynter Blyth for the examination of disinfectants (Roy. Soc. Proc., 1886, No. 240), with certain stringent and necessary precautions. Whatever may be thought of Rideal and Walker's method as a guide to the strength or efficiency of a disinfectant, they have undoubtedly given us a standard method of working which has been of the greatest value in the study of germicidal values.

As a result of Rideal and Walker's suggestion, the Council of the Royal Sanitary Institute appointed a committee to consider the desirability of establishing a standard bacteriological method for determining the efficiency of disinfectants. This committee, which consisted of a number of eminent men—but unfortunately no representative of the commercial side of the question—after having some experiments carried out, and considering the question, no doubt with great care, presented in April, 1906, the following report to the Council of that body.

1. "The Committee are of opinion that no one method of testing disinfectants can indicate their relative values under every possible condition. These must be specially determined for the given case required, and where penetration is important a 'Thread method' is indicated."

2. "For general purposes, on account of its simplicity of working, the Committee recommend the 'Drop method,' as described in the J. of the Roy. San. Inst., Vol. XXIV. (1903), page 424."

"The test to be carried out with pure broth cultures of the *B. typhosus*, using sterilised distilled water as the diluent of the disinfectant."

"All nutrient broth to have a constant reaction of +15."

"Where special conditions exist, which may intertere with the activity of the disinfectant, the consumer should be advised to call for the same conditions to be embodied in the test."

This report was adopted by the Council of the Royal Sanitary Institute, but almost immediately withdrawn, and the Committee have since then been silent. I should have passed over this abortive report, but that it has had an important effect on the question of the standardisation of disinfectants. Whether the report should ever have appeared in the public press is not a question I am prepared to answer, but as a fact it was published in the "Lancet" and other journals, and has given more or less an official sanction to the Rideal-Walker method of testing and expressing the efficiency of disinfectants. This report, and the publicity which has been given to the question by papers in scientific journals, and the free advertisement of carbolic acid coefficients, combined with the real need which is felt for some guarantee of the germicidal value of disinfectants, has resulted in the Rideal-Walker method being more or less generally accepted. The position to-day being that Government departments, municipal councils, and other large bodies are contracting for disinfectants on the Rideal-Walker coefficient, while manufacturers are vieing with one

another in their endeavours to raise their coefficients to the highest possible limits.

It must not be forgotten that a standard test should be one which will discriminate fairly not only between worthless articles and the moderately good and very good ones, but also between the many very good disinfectants at present on the market. Practically any bacteriological test carried out under similar conditions will distinguish between, for instance, the worthless mixtures so often sold as carbolic powder, and a really genuine carbolic powder; but it takes a method of great accuracy to distinguish between such high-class disinfectants, as, for instance, Izal, Cyllin, Kerol, Lysol, and similar substances. Messrs. Rideal and Walker, in proposing their standard test, evidently thought that they had at least the essentials of a method sufficiently reliable to distinguish between high-class disinfectants.

I propose in this paper first to consider a few factors which influence the germicidal value of a disinfectant as determined by the drop method, and then to criticise the Rideal-Walker method, and to make a few suggestions as to the direction in which I consider tests as to the germicidal value of disinfectants might be improved

Influence of organic matter.—It is a matter beyond dispute that in anything requiring disinfection, organic matter is always present, and in the vast majority of cases the quantity of organic matter is large, and, compared with the volume of the disinfectant, enormous. In considering the real efficiency of a disinfectant, the possible influence of organic matter cannot be neglected. The difficulty is to know what organic matters to select. In the experiments recorded here I have taken as typical organic matter to which disinfectants are likely to come in contact in practice: fæces, urine, and blood. I have also taken milk in order to compare the effects of this substance with that of the others. The possible number of organic substances with which a disinfectant may come in contact is very large, but I submit that fæces, urine, blood, and milk will at least give an idea as to whether organic matter is of sufficient importance to be taken into account when considering the efficiency of disinfectants. But little work has been done in the past on the influence of the presence of organic matter upon coal tar disinfectants, although the oxidising disinfectants have lately received considerable attention. Kenwood and Hewlett (J. Roy. San. Inst., Vol. 27, No. 1) took disinfectants of a uniform strength of 5 per cent., which were added directly to and thoroughly mixed with 25 c.c. of typhoid fæces and of urine, and, after half an hour's exposure, inoculations were made into a suitable medium (McConkey's bile salts medium in Durham's tubes, and Conradi plates). These were incubated up to three days at 40° to 42° C., and the carbolic acid coefficients obtained by treating standard phenol in the same manner. Carbolic acid coefficients of the disinfectants in tap water and in distilled water, without the organic matter, were also obtained. (See Table I.)

There are one or two important points which must be taken into consideration in comparing these results. 1st, the amount of organic matter is variable, more being present in the disinfectant solutions than in the control; this, as I shall show, would tend to make the real coefficients too low. Secondly, the use of tap water, as shown by Mr. T. H. Lloyd (this J., 1906, 405 *et seq.*) tends to make the co-efficients low, but the conditions being the same in the organic and water solution, this factor may be disregarded. The fact that in one case naturally occurring *B. coli* was used, and in the case of the tap water, *B. coli* incubated in broth for 24 hours, is a factor which cannot be neglected, for not only is the dosage different in the two cases, but my experience is that the varieties of *B. coli* as they exist in fæces vary somewhat widely as to their resistance to disinfectants. It is probable that this difference in resistance has an influence on the coefficient obtained; this is a point to which I wish to refer later The broad fact remains from these experiments, since these factors are not sufficiently serious to effect this conclusion, that fæces have the effect of enormously reducing the carbolic acid coefficient of the disinfectants examined. The objects of Kenwood and Hewlett's experiments, it should be mentioned, were in no way connected with the influence of organic matter as such, but were intended to demonstrate the values that are obtained for disinfectants when used under practical conditions.

Turning to the experiments carried out by Major Fowler (J. Roy. San. Inst., **27**, No. 1), working under the direction of Lieut.-Col. Firth and Prof. Macfadyean, we find five recorded as the coefficient of "Disinfectant No. 1" at 65° C. (one experiment only), and 8·55 as the coefficient of "Disinfectant No. 2" (one experiment only). These coefficients were obtained by adding various dilutions of the disinfectant to tubes which contained when diluted half their volume of a filtered mixture of 1 grm. of fresh human fæces and 100 c.c. of fresh human urine. The solid fæcal matter present in such a mixture would be extremely small, and the experiments are too few in number to deduce any definite conclusions; but as far as they go they confirm the fact that the presence of urine has not a great influence on the coefficient of the disinfectants examined.

Somerville and Walker (The Sanitary Record, Vol. 38, No. 887, p. 485) record some experiments in which, in addition to urine, 1 per cent solutions of serum, mucin, peptone, casein and gelatin, were taken as types of different forms of organic matter, and it is suggested that the method can be utilised to classify disinfectants and to compare their germicidal value when encountering different forms of organic matter. With regard to the solutions of peptone and casein, they give us no clue to the influence that these substances *in their natural state* would have upon the germicidal value of disinfectants, as the authors have dissolved the substances in sodium carbonate. The experiments on serum and blood, in more or less their natural state, demonstrate admirably the uselessness of drawing any conclusions from the use of very small quantities of organic matter with disinfectants of Class D, since it could be inferred that 50 per cent. of serum or blood would render them absolutely useless as germicides—an inference which would be most unfair to the coal tar disinfectants.

In the experiments recorded here I have adopted a slightly different method from that recommended by Messrs. Rideal and Walker, the modification being 10 c.c. of the diluted disinfectant in distilled water, and six drops of standard broth culture incubated for 24 hours at blood heat. My only reason for using this modification being that I have results obtained by the method recommended

over several years. It gives results in distilled water almost identical with the Rideal-Walker values.

Germicidal values in water.—These were taken in distilled water at temperatures varying from 14° C. to 18° C., and were obtained with typical *B. coli communis* (Houston's "Flaginac"). The numbers recorded in the tables are the mean values of a large number of experiments, and indicate the volume to which the disinfectant has to be diluted with distilled water (or with the particular organic fluid) in order to kill the organism in 12½ minutes' contact, but not in 10 minutes.

Fæces.—A little water was added to normal fæces and the mixture ground up in a mortar to as homogeneous an emulsion as possible. Five grms. of this mixture (fæces-emulsion), or definite dilutions, were weighed into several corked test tubes. The total solids in five grms. of the emulsion were determined by drying at 100° C. The nitrogen was determined by Kjeldahl's method, and fat by extracting with ether. To the test tubes containing 5 grms. each of fæces emulsion or the diluted emulsion was added 5 c.c. of various dilutions of the disinfectant; the volume so obtained was considered to be equal to 10 c.c., and the dilutions have been calculated on this assumption. The mixture of the disinfectant and fæces, after thoroughly shaking, was allowed to stand at least one hour. Inoculations were then taken into nutrient broth, the tubes incubated in the usual way, and later subcultured to detect organisms of the *coli* group; if any positive results were obtained, all further experiments with these tubes were rejected. Six drops of a 24-hour culture of typical *B. coli communis* were then added and the tubes shaken, and inoculation made into broth at intervals of 2½ minutes, three platinum loopfulls of the fæces-disinfectant mixture being taken for each inoculation. The experiments were made at temperatures between 14° C. and 18° C. By diluting the original fæces emulsion with distilled water, the 5 grms. of fæces were made to contain less and less organic matter as required. The total solids of each dilution of the emulsion were always checked by drying at 100° C.

It was not found possible to work, or to get a satisfactory mixture with a disinfectant, with an original fæces emulsion containing more than 14 to 15 per cent. of dry solids (7—7·5 in the fæces disinfectant). Experiments by this method were made on mixtures containing about 2·0 per cent., 4·8 per cent., 6·1 per cent., and 7·2 per cent. of total solid matter. Where the solid matter was slightly different from these figures, a slight correction has been made for the purpose of comparing the figures recorded in the table.

In illustration of the method the following results of one series of experiments may be given. The results given in the tables are, however, the mean results of many such experiments, and this plan has been followed throughout the experiments with urine, blood, and milk.

the broth culture. The specific gravity and nitrogen of the urine was determined in every case.

Blood.—A few experiments were made with fresh human blood, 5 c.c. of the blood being mixed with 5 c.c. of the diluted disinfectant.

Milk.—Experiments were made with (1) fresh milk with all its fat; (2) condensed milk with all its fat (Anglo-Swiss brand); (3) separated milk; (4) condensed sweetened separated milk.

It was found possible in the case of the condensed milks to work with 40 per cent. milk solids (20 per cent. in the dilution) in the sweetened milk, and 30 per cent. of milk solids (15 per cent. in the dilution) in the sweetened milks. Dealing only with the coal tar disinfectants, it was found that results similar to those obtained with diluted unsweetened condensed milk were obtained with fresh milk, provided the solids were the same, and they contained the same percentage of the fat, and results similar to those obtained with diluted sweetened milk were obtained with separated milk containing the same fat and solids; in other words, the influence of cane sugar upon these disinfectants is very small. Experiments previously recorded ("Analyst," **31**, No. 362) show the influence of milk sugar to be also very small, and, further, from my experiments with fæces, I think it is not too much to say that the whole class of carbohydrates has little if any influence on the germicidal efficiency of coal tar disinfectants. The following table gives the average composition of the organic substances used in these experiments:—

TABLE III.—*Fæces-emulsion:—Total solids, 12·4 per cent.; ether extract, 2·6 per cent.; nitrogen, 0·9 per cent.; carbohydrates, about 3·0 per cent.; ash, 1·2 per cent. Blood, human, not analysed. 50 per cent. used in experiments. Urine, sp. gr. 1·020; nitrogen, 1·5 per cent.*

For the purpose of reference the disinfectants examined have been roughly divided into the following classes:—

Class A., Phenol. Class B., Cresylic acid (Trioresol). Class C., Disinfectants containing carbolic or cresylic acids, and giving a clear solution with distilled water. Examples: Lysol, Cooper's fluid, cresylic acid and soft soap, &c. Class D., Division (α) disinfectants containing little or no carbolic or cresylic acids and giving an emulsion with distilled water. Examples: Kerol, Cyllin, Izal, Bactox, &c. Division (β) disinfectants containing carbolic or cresylic acids, and giving an emulsion with distilled water. Examples: Emulsified cresylic acid and many commercial disinfectants. Class E., Disinfectants giving a clear solution both in distilled water and tap water. Examples: Formalin, Chinosol, pyrogallic acid, &c. Class F. Oxidising or semi-oxidising disinfectants.

If we examine these tables, it at once becomes apparent that with the disinfectants of Class A to D, the introduction of fæces or milk or blood has the effect of reducing their germicidal efficiency as judged by the drop method. It will further be noticed that while the drop is at first sharp, it tends to become less and less as we introduce more and more matter, until it tends to cease altogether. We may, in fact, by taking as abscissæ the amount of organic matter present in each experiment, and as ordinates the effective dilution in each experiment, determine the position of a number of points. These, when joined up by lines, form rough curves, which if the intermediate points had been determined, and if no error of experiment existed, would probably be perfect curves, which all tend to become straight lines; in other words, a point is reached, its position depending on the nature of the organic matter and the particular disinfectant, where the introduction of more organic matter into the test would have no further influence on the efficiency of the disinfectant. This is, I think, a most important point to keep in mind when considering disinfectants of this class, for it shows that although a disinfectant may lose a certain amount of efficiency in the presence of organic matter, yet it may be a most excellent and certain germicide even in the presence of an enormous quantity of this organic matter.

The milk curve for a particular disinfectant was in each case found to be lower than the separated milk curve. This difference is undoubtedly due to the fat, which is one of the chief factors in lowering the germicidal efficiency, nitrogenous bodies of the albumin class being the other. ("Analyst," 31, No. 362.) The influence of albumin is well illustrated by the effect of 50 per cent. blood on disinfectant Dα1. In every case the curve for each disinfectant in fæces lies somewhere between the curves for the disinfectant in separated milk and milk, and follows the same course.

The fat (ether extract) in the fæces experimented on has an average value of 2·6 per cent., and the fat in the milk an average value of 4·0 for more or less the same amount of solid matter; so that if we only had to consider the fat, we might expect the curves to lie almost exactly as they do. The nitrogen in the fæces is higher than that in the milk, and its influence cannot be neglected; however, all the nitrogen of the fæces does not exist as proteids, and if these substances or closely allied ones are the only ones in addition to fat which influence the germicidal efficiency of the disinfectants, we cannot speculate on the probable influence of the nitrogen, unless we actually estimate the amount of proteid nitrogen present. Fæces is, however, such a complicated and variable mixture that it is a profitless task to consider all the possible influences which may come into play. I think, however, that carbohydrates may be neglected (with disinfectants of classes A to D); and the influence of bile salts is practically *nil*. The broad fact remains that the curves in fæces follow those in milk and separated milk, and it is obvious that by making a mixture of milk and separated milk, the influence of fæces of any given composition can be, if not be exactly imitated, at least very closely indicated.

Oxidising disinfectants.—With oxidising or semi-

oxidising disinfectants there are, I think, two things to be ascertained with regard to their action in organic matter. (1) What is their value when added to substances already containing the germs? (2) What is their value when the germs are added to the organic matter containing the disinfectant?

With regard to (2), the value obtained will depend in the presence of a large amount of almost any organic matter almost entirely on the time which is allowed to elapse before adding to the disinfectant—in other words, if the germs are not added fairly quickly they will not be killed at all. And this is one of the main advantages of the coal tar disinfectants over the oxidising disinfectants. With the coal tar disinfectants, whatever may be the influence of organic matter on the initial efficiency, it does not destroy the disinfectant. The disinfectant will, if given sufficient time, exert its influence even in the presence of large amounts of organic matter.

Experiments were made with potassium permanganate and F.I. in milk, six drops of the *coli* broth culture being added to sterilised milk before adding the disinfectant, the time being taken from the time of emptying the pipette. It may be said at once with regard to F I., that it apparently had no oxidising effects, the values and curves obtained corresponding very closely to the coal tar disinfectants, except that it is influenced very much by the presence of fat.

With potassium permanganate no curve was obtained, the fall in efficiency being a straight line. Unfortunately want of time has prevented me making experiments in fæces and in separated milk; but it is obvious that, providing it is proved that carbohydrates influence this disinfectant, as it is certain they will, the fall of efficiency in fæces would be greater than that in unsweetened milk.

The point I wish to emphasise here is that the fall in efficiency in organic matter of a real oxidising disinfectant is proportionate to the organic matter, and may be represented not by a curve but by a straight line, and that these disinfectants will be influenced by any oxidisable organic matter whatever.

The micro-organism used and the strain of micro-organism.—The particular micro-organism which is to be used in a standard test is of considerable importance, especially when we remember that it is suggested that the quantity of any given disinfectant which may be used in higher resistance than *B. typhosus*, and that then, even if the drop method on naked organisms did represent a real difference between any two different disinfectants, the difference would not be the same when the disinfectants were required to kill a more resistant organism.

The influence of variation in strain of the micro-organism used has been referred to by Lieut.-Col. Firth and Prof. Macfadyean (J. Roy. San. Inst., **27**, No. 1). "Too much importance," they say, "must not be attached to it, as the experiments show that the behaviour of several strains of *B. typhosus* in the presence of various disinfectants in corresponding solutions is remarkably similar. We are impressed with the fact that different strains of *B. typhosus* present certain differences as to tendency to clump, and for this reason admit some predilection for the employment of filtered cultures of this micro-organism, but the error from this source we think is small, provided that due care be taken to see that the particular strain employed is normal in all its cultural features. If we now turn to the record of the experiments carried out by Major Fowler, and upon which, presumably, the above remarks were based, we find that for one disinfectant the carbolic acid coefficient determined on broth cultures of *B. typhosus* varies from less than 6 to more than 11 as the result of eight recorded experiments—it is true that these observers say that "before stating that any given disinfectant has a definite coefficient as against a particular micro-organism by this or any other method, the same result should be obtained in not less than three out of five observations." I suggest, however, that the influence of different strains of organisms might account in part for these different results, and that before any organism is adopted as a standard organism, especially if the organism is liable to clump, and has such apparently widely different powers of resistance as judged by the experiments of Major Fowler, sufficient experiments should be carried out to settle the question decisively if possible. As the work recorded here was performed with typical *B. coli*, the question of strain of organism naturally arose—although in this case it is not so important, as my figures are based on average results. Dr A. C. Houston kindly supplied me with a series of typical and *a*-typical *coli* organisms; time has not yet permitted me to make a complete examination of the whole of these organisms. Of those examined the following results were obtained:—

TABLE IX.

Organism Coli No	Gas in gelatin shake culture.	Cane sugar peptone-culture acid and gas.	Fl = Fluorescence in neutral red broth.	Ag = acid and gas in lactose peptone cultures	In = indol in broth cultures.	Ac = acid and clot in litmus milk cultures	Dilution of phenol which kills in 12½ m. and not in 10 m. at 15° C.	Dr. Houston's classification.
1	+	+	+	+	+	+	1:80	Flaginac
2	+	+	+	+	+	+	1:80	Flaginac
3	+	+	+	+	+	+	1:80	Flaginac
4H	+	—	+	+	+	+	1:70	Flaginac

6	+	—	+	+	+	+	1:70	aginac
7	+	—	+	weak	—	—	1:100	Fl(ag)
8	+	—	+	—	—	—	1:110	Fl.

the practical work should be governed by the experimental coefficient. It has been proved by several workers that the carbolic acid coefficient of a disinfectant which, tested by the Rideal-Walker method against *B.* gives a value of 11, gives with typical *B. coli communis* a value of from 6 to 8. From a number of observations made on organisms of varying resistance to phenol, and from an examination of the figures given by other workers, I do not think it is too much to say that in the majority of cases, if not in every case, if carried out under exactly the same conditions, the higher the resistance of the organism to phenol the lower will be the coefficient obtained. *B. typhosus* is no doubt the best representative of the fæcal pathogenic organism, but the fact must not be lost sight of that disinfectants will often be required to kill organisms of a

The four strains of typical *coli* examined gave as the average of six experiments on each a value of 80. One typical in every one of the above characteristics except that it did not ferment cane sugar peptone, gave a value of 70. It would appear, as far as these limited experiments go, that when working with *B. coli* it is sufficient to determine its "flaginac" character and its power to ferment cane sugar.

These cultural features must, however, be determined, as *a*-typical *coli* (some at least) have very different resistances and give quite different carbolic acid coefficients. For instance, *Coli* No. 8 with disinfectant DaII. gave a coefficient (one experiment only) which was nearly as high as that which *B. typhosus* gives.

The thread method.—A number of experiments were

made with the thread method, using 24-hour old cultures of *B. coli communis* grown on agar, with the general result that coefficients conspicuously lower than those given by the drop method were obtained. This is quite in accordance with the work of other observers. A modification of the thread method was tried in order to ascertain, if possible, if the disinfectants containing soaps had any power of removing and penetrating the dried organic medium in which organisms might be embedded. The modified method was as follows: Standard sterile silk threads were placed in standard broth, which was then inoculated with the organism and incubated for 24 hours at blood heat. The threads were then removed and hung singly over a sterile wire suspended inside a sterile beaker and covered with a sterile Petri dish. They were then placed in the incubator and dried at blood heat for 24 hours—the subsequent proceedings were as in the ordinary thread method with naked organisms. The method of working gave with the majority of the emulsion-forming saponaceous disinfectants a conspicuously higher coefficient than does the ordinary thread method, and gave far more uniform results. It is, I think, also a little more analagous to the conditions which might be met with in practical disinfection, when the organisms are always imbedded in a more or less resistant organic medium.

The following results were obtained by the two methods, the figures representing dilutions effective in 12½ minutes as before.

TABLE X.—*Thread method.*

D—II.	70	60	1.	1·5
E II.	1 not effective in the time.	—	—	—

In the light of these experiments, let us consider whether the Rideal-Walker method or any other modification of the drop method carried out on naked organisms is a reliable guide to the germicidal efficiency of a disinfectant when used for practical purposes. The answer to this has been—No, but it is the best test we have at present, and it gives a very good idea of the relative value of disinfectants. Further it has been stated that it can be modified to meet the requirements of special cases. I would ask those who say this to give any instance where disinfection was required which was not a "special case," or any instance of bacteria living without organic matter to live on. What modification would a borough engineer call for, when ordering disinfectants in bulk for putting on the roads, pouring down gullies, flushing urinals, or treating refuse heaps? This plea for modification for special cases is, I am quite convinced, absolutely impracticable, it would lead to endless trouble and discrepancies, and be desirable neither from the consumer's nor from the manufacturer's point of view. Let us first consider the question as to the utility of the Rideal-Walker coefficients from the commercial point of view. Disinfectants are being bought and sold at present on this coefficient. Is this always fair to all disinfectants? The tendency of the germicidal values of the high-class coal-tar disinfectants in the presence of some forms of organic matter, is to approach one another, and even in some cases to actually change places in order of merit as shown by the tables. The points of greatest difference coincide with the value obtained in distilled water.

To take a concrete instance, a disinfectant A costing 2s. per gall., has a Rideal-Walker value of 7, and another, B, at 1s. per gall, has a coefficient of 2. In the one case seven units are obtained for 2s., in the other four units for 2s. A is better than B. Now introduce 4·8 per cent. of solid fæcal matter into the test, and let us suppose we get coefficients of 2 and 1·5 respectively, *i.e.*, in A one obtains two units for 2s., and in B, three units for 2s., or B is better than A. Is it fair to B to sell or buy on the Rideal-Walker coefficient? Another instance of the impossibility of relying upon the drop method in water, is a common form of specification for the supply of disinfectants for use in the county borough. For instance, at Brighton, the schedule for the supply of disinfectants runs—"Carbolic acid—To contain at least 95 per cent. of tar acids, to be of the quality commercially known as No. 5, free from tar oils, containing at least 10 per cent. of an available crystallised phenol, and to be wholly soluble in twice its volume of a solution of caustic soda of sp. gr. of 1·070."

Contractors supplying disinfectants to meet these conditions, could, and I have no doubt do, supply articles of widely different germicidal value, and the introduction of a guarantee of germicidal efficiency is not only desirable, but in view of the importance of municipal disinfection, absolutely essential. Let us for the sake of argument introduce the words "shall have a carbolic acid coefficient as determined by the Rideal-Walker method of 0·95." In other words, what is required is an acid or mixture of acids equal in efficiency to 95 per cent. carbolic acid. Now the carbolic acid coefficient of cresylic acid is about 2, so that one contractor might supply an article containing 95 per cent. of real carbolic acid, another 10 per cent. of carbolic acid, and some 50 per cent. of cresylic acid, both would have about the same apparent efficiency. Introduce a fæces emulsion, however, into the test, and the cresylic acid mixture at once falls below the 95 per cent. phenol. It is obvious that the two substances cannot be compared as to their real value by their action on naked organisms. Incidentally it may be mentioned that I have under investigation at present a method for determining the proportions of carbolic acid to cresylic in a mixture of these two substances by observing the difference in germicidal value in organic matter (milk). If we disregard the commercial side of the question and look upon the carbolic acid coefficient as a guide to the quantity of disinfectant we should use for any practical disinfection, it can be clearly seen that, if we disregard the possible influence of organic matter, we run a grave risk of not using sufficient disinfectant, and this is true even when we allow a very large margin of safety. Nobody will deny that it is desirable to introduce organic matter in some form into the drop method test—the question is what organic matter, and what quantity. Fæces is to my mind the type of all organic matter that requires disinfection. If a disinfectant will disinfect fæces, I think we may safely infer that it will disinfect blood, pus, urine, or any other common organic fluid.

If various dilutions of a disinfectant, mixed with various definite qualities of a perfect emulsion of fæces, had consistently a carbolic acid coefficient of at least 10, whatever quantity of fæcal solids was present, provided the same quantity of fæcal solids was present in the control, then I should have no hesitation in saying that the disinfectant had an efficiency coefficient of *at least* 10. But fæces vary very greatly in composition, especially as regards the fat. We might take the average composition of fæces, and decide that a certain quantity of such fæces should be our standard organic matter. But it would be impossible to insure a supply of such average fæces, and further, apart from the disagreeableness of working with such a medium, consistent results cannot be got even with careful grinding and mixing, unless we average up a considerable number of experiments. If fæces cannot be used, can we use a substance in the place of fæces that will give the same result? I have already shown that with certain disiufectants the curve obtained from fæces of a given composition lies between the curves obtained from separated milk and whole milk. Milk can be obtained practically anywhere; it contains no lumps, it gives consistent results, and by the use of separated, rich or poor, condensed, skimmed, or condensed whole milk, its composition can be varied at will. Its analysis is probably simpler and more accurate than any other natural organic fluid. I believe it is possible to decide on a composition of milk which will exactly represent, with regard to its influence on germicidal action, an equal weight of solid acreage fæcal matter. What the composition of the

milk should be, or what is average fæces, or what quantity of solid matter should be taken, I do not at present feel in a position to suggest. My present feeling is that we should, if we can imitate fæces, find out the lowest limit to which the coefficient of each disinfectant can be driven down by the addition of our artificial fæces, and that we should then give the disinfectant credit for this value and for every value above this right up to the value in distilled water. This, I think, would be fair to those coal-tar disinfectants with a high Rideal-Walker value, and which are so very effective in the presence of small quantities of organic matter, and would give us some idea of a relative efficiency of disinfectants as judged by the drop method.

Even if we introduce some organic matter into the drop method, the question arises as to whether it is safe or expedient to judge disinfectants upon the results of one particular method of working. In other words, can the efficiency of a disinfectant be expressed by one figure. Desirable as this may appear, at least from a commercial point of view, I personally do not think it possible. For instance, I do not think we can entirely ignore the results obtained by the thread method, or a modification of this method. This method, whatever its failings may be, at least indicates that there are certain conditions under which certain disinfectants more nearly approach the germicidal value of carbolic acid. And these conditions in the case of more or less naked dried organisms on animal and vegetable tissues are likely to be met with very frequently in practical disinfection.

Can the efficiency of a disinfectant be expressed by more than one figure? Here I see no insurmountable difficulty. Analytical chemists are in the habit of judging the value of articles by not one figure, but by a whole series of figures—in fact few, if any, articles are judged by the result of one test: why then should bacteriologists be bound down to one test if that test be shown to be inadequate? I submit that it is impossible to assign to disinfectants on figure which will represent their relative or absolute efficiencies, but that we may by, a combination of the drop method in water and in organic matter with thread methods, assign to disinfectants a series of figures which will more or less indicate their relative efficiencies as tested against the particular organism used.

In conclusion I must tender my best thanks to those medical officers of health who have supplied me with information as to the quantity and nature of the disinfectants used in their districts, and the purposes to which they are applied; to Dr. A. C. Houston for supplying me with a series of cultures; to Mr. L. Goodban for making some of the analyses in connection with this work; and to various manufacturers for sending me samples of disinfectants.

Discussion.

The Chairman said that these different disinfectants most probably consisted of varying quantities of soft soap, hard soap, more or less water, and a little cresylic or carbolic acid. He should like to know whether the organic matter was determined by drying at 100°; under such conditions carbolic acid would volatilise to some extent, and the soap and other solids would remain behind. He did not think it right to replace fæces, which was the ultimate substance they wished to disinfect, by milk—a substance of very different composition.

Dr. A. Wynter Blyth thought it was very creditable to the Royal Sanitary Institute that, when a report was put forward somewhat prematurely, they had the courage to withdraw it. This was done because the Disinfectant Committee believed certain points required further consideration. One of the chief points of the paper seemed to be that a considerable amount of organic matter altered the relative values of various disinfectants. Those engaged in the manufacture of tar acids and other disinfectants knew that it was of very great importance to get some standard test. He was sure that Messrs. Rideal and Walker would be the last to consider their proposal as final. No doubt, like all tests when first proposed, it was susceptible of improvement.

Dr. Martin pointed out that the credit of finding a rational standard method of comparing disinfectants was due to Messrs. Rideal and Walker. Most workers agreed that the same organism must be employed for the comparison. The same temperature was essential, for Miss Chick's researches had shown that different disinfectants had varying temperature coefficients. Again, the number of organisms must be constant in a series of experiments, and a standard time must be agreed to, because the influence of dilution upon the time taken to kill bacteria varied with different germicides. Mr. Blyth had put it at 12½ minutes. It was necessary, therefore, to have the same organism, the same number, the same temperature, and the same time. He was in complete agreement with Mr. Blyth on the question of organic matter. They did not want to disinfect drinking water, but masses containing much organic matter. From experiments which had taken place under his inspection he could confirm the results represented on the curves for such substances as milk. One of the test conditions they would have to consider would be stools from infectious diseases such as typhus. Every chemist would realise that the effect of an oxidising disinfectant or of one forming precipitates in presence of organic matter would be greatly diminished. Disinfectants were readily absorbed by porous matter such as animal charcoal. All the emulsified disinfectants were made of the higher cresols, together with soap or glue, or something of that nature, to keep them in suspension. He did not wish to depreciate them; they were very useful disinfectants, but it was necessary to find out what their real value was. Twenty years ago both Behring and Esmarck experimented with Pearson's creolin, in presence of fæces and of blood serum, and obtained the same results as Mr. Blyth did. As regards the suggested standard, he had, personally, an objection to using milk instead of fæces, because for some purposes, *e.g.*, a sporing organism, he would have to standardise against mercuric chloride and not carbolic acid. With fæces it was possible to approximate towards accuracy by utilising emulsions made with constant amounts of dry sterile fæces. Dry fæces were unobjectionable and gave consistent results, and possessed the advantage of being one of the types of organic matter to be dealt with in practice.

Prof. Kenwood said that Prof. Hewlett and himself, almost immediately after Dr. Rideal and Walker's suggestion was made, criticised it adversely on the score that it did not include organic matter, and he thought now that the authors themselves were convinced of the necessity of including organic matter in a test of the germicidal powers of a disinfectant. It might be of academic interest to learn that certain naked organisms were killed by disinfectants of certain strengths, but when those strengths were advertised and used for trade purposes, they gave a terribly misleading conception to the general public and to purchasers of how these disinfectants should be employed in practice. The author asked whether it was fair that disinfectants should be bought and sold under the Rideal-Walker test, and conclusively showed by his experiments that it was not fair, and that, until it included organic matter, the method was not of real value. If disinfectants were to be purchased on the Rideal-Walker basis, there was one which far surpassed all others, and was much cheaper. He meant permanganate of potassium, which was the disinfectant *par excellence* by the Rideal-Walker method upon a naked germ, whereas in the presence of a little organic matter it figured very badly. Mr. Blyth first of all pointed out the marked effect which fat had on all these disinfectants, and he had confirmed his results upon milk. He agreed with Dr. Martin that fæces was undoubtedly the best medium to work with. The author had shown that with even 7 per cent., which in his opinion was not an excessive amount of solid matter, all the disinfectants in the first two groups were practically equal. If he had carried the experiments on with a little more organic matter, doubtless they would have been almost, if not quite, identical. In an endeavour to ascertain what material other than fæces could be used for standardising disinfectants, he had experimented with flour and found that that had too little disturbing effect, no doubt due to

its freedom from fat. On the other hand, Hewlett and himself had been recently conducting experiments on pus, and with this the disinfectants in the first two groups had coefficients of about 2. The great levelling effect of pus was explained by the fact that it contained a large percentage of fatty matter. It was perfectly obvious to him that it was not right to demand that disinfectants should always be used at the strength found necessary to disinfect fæces. Considerable waste would result, and therefore he agreed with Mr. Blyth's suggestion that for each disinfectant a series of factors was necessary to determine what was its real value under varying conditions and circumstances.

Mr. C. T. KINGZETT said with respect to fat it must be borne in mind that most disinfectants with which the author experimented were those of an emulsified character, which, when diluted with water, immediately split up into their aqueous portion, and the oily portion constituting the active principles. These would vary with each preparation. The interference of the fat was brought about doubtless by assimilation of these oily particles with those of the fat present in the mixture, and this was one of the most disturbing factors in ascertaining the germicidal value of such preparations. Fæces, apart from the disinfection of stools in infectious cases, was not a matter of much difficulty, and could be done quite well by the use of common lime. All that had to be done with the fæces of town and country was to collect it, remove it, and dispose of it. The question of disinfection did not arise on so large a scale. The bacterial method of testing disinfectants was open to the cardinal objection that it did not test the real disinfectant value, but only the relative germicidal values under the particular set of conditions observed, and those did not simulate the conditions under which disinfectants were used in practice. There was no absolute scientific test for ascertaining the relative values of disinfectants, and could not be until they had greater knowledge of their nature and constitution. Bacteria were not themselves infectants, only the agents of their production, and nothing was known with certainty of the precise conditions under which they were produced, or of their constitution. The relative values of disinfectants could not be measured by germicidal power under an artificial set of conditions, but only by the determination of all contributory chemical and physical qualifications and disqualifications. The germicidal value was of importance, but the antiseptic value was equally important, and more important still was what might be called the "oxidative value." All these properties, however, were of mere temporary value, because in the end the organic matter containing the infectant must be disposed of by oxidation, either rapidly, as by combustion, or, more generally, in the natural manner by the action of the very micro-organisms to which germicides were fatal. To that extent, therefore, the use of strong germicides was objectionable, because they prevented the natural operation by which ultimate purity and freedom from infection would be secured. The relative values of disinfectants primarily depended upon their adaptility to the required purpose, and no bacterial test afforded an acceptable basis for comparison. One strong objection to the bacterial test was the impossibility of standardising the culture, upon which subsequently everything depended. The most expert bacteriologist could not guarantee the purity and unmixed nature of the organisms. Another difficulty was the varying chemical and physical actions of the disinfectant, not merely on the organisms themselves, but also in respect of the culture medium. Combination, coagulation, precipitation, obscuration were all experienced in practice, and the results were only of value as regarded the one preparation in question. For the last twelve months Mr. R. C. Woodcock and he had subjected the Rideal-Walker test to considerable study, and they found that while fairly uniform results might be obtained, using the same preparation and the same culture, by the same experimenter, varying results were obtained by other experimenters, using the same materials. For example, a certain disinfectant which exhibited a relative efficiency of 12·6 and 13 respectively as determined by A., only gave 8·6 as determined by B., using the *B. typhosus* test. The efficiency was known to vary according as the broth was neutral or acid. In this case the high results were obtained using plus 15 broth, whilst only an efficiency of 8·5 was obtained by the same experimenter using neutral broth. When tested against *B. coli* by the same experimenter, the relative efficiency came out at 6·7. With certain other disinfectants identical results were obtained whether the broth was neutral or acid—a very important consideration. It was further to be noted that one disinfectant would show a superiority as compared with one organism, but an inferiority when tested against another organism. Finally he would call attention to a remarkable experience. A certain liquid of strong germicidal value was determined to have a relative efficiency of 9·5. It was then split up by chemical extraction into two parts, constituting 27 and 73 per cent. respectively; the smaller portion, when tested in precisely the same way, showed an efficiency of only 1·8, whilst the 73 per cent. gave a figure of 3·5 only. Another liquid with an original relative efficiency of 10 was similarly split up, when 15 per cent. showed a relative efficiency of 3, whilst the other 85 per cent. showed a relative efficiency of 8·5. He felt quite sure they would never arrive at any chemical or other standard for determining the relative value of all disinfectants.

Dr. S. RIDEAL said the paper resolved itself practically into (1) a recommendation of carbolic acid as a standard, and (2) of expressing the efficiency of a disinfectant as a coefficient of such standard, in the way originally introduced by Mr. Walker and himself. Mr. Blyth had brought forward a certain amount of destructive criticism as to the incompleteness of this test alone, but he had suggested no alternative, but contended that, in addition to this test, another should be simultaneously carried out, in which organic matter was purposely added. Instead of fæces, a mixture of separated and whole milk was used, and the author contended that this mixture would give a result which was similar to that of fæces. He had not, however, produced this mixture or shown that the curve was identical with that of fæces, but had relied on a diagram of his tests indicating that fæces influenced the coefficient in an intermediate way between whole and separated milk. The expression "average fæces" was somewhat startling, and he could not understand what was meant by such a mixture. He differed from Dr. Martin in considering that fæces was a material which could be used as a standard in any test. He thought Mr. Kingzett was correct in saying that it was not the disinfection of typhoid stools that all these tons of disinfectants were sold for, and, moreover, a typhoid stool was not normal or average fæces. They got from the papor the idea that the Rideal-Walker test was necessary; and, secondly, that this substitution of a mixture of milk to imitate average fæces was a corollary to the first test. But why should this be? It could only be in the limited number of cases in which the disinfectants were to be used in contact with fæces; the result of introducing organic matter, whether milk or fæces, into a test was to bring closer together the carbolic acid coefficients for the different disinfectants. No one had put forward any medium which would separate the different classes of disinfectant to a greater extent from another than when the test was carried out as originally suggested by himself and Mr. Walker, *viz.*, in the presence of distilled water. The modified test, therefore, had the effect of bringing the disinfectants closer together in numerical value instead of separating them; but surely if the Rideal-Walker method did not separate the various disinfectants sufficiently, they ought to supplement that test by one which would separate them still further from one another. It must be obvious that if the "naked bacteria" are sufficiently enveloped in fats and other organic matter, they are more difficult to kill by all disinfectants. By pushing Mr. Blyth's argument far enough, one gets to a condition when the bacteria are so protected that the carbolic coefficients for all the disinfectants are identical. He agreed with Dr. Martin that there should be uniformity, whatever test was adopted, but it seemed a pity that a test which had been adopted by the War Office, the Navy, several of the Colonies, and Municipal authorities in this country, even if it was not perfect,

should be displaced by some other test based on slender evidence and of which they knew comparatively nothing.

Dr. SOMERVILLE said he was glad to find so many agreed that some such standard test was necessary, and also that there should be an addition of organic matter, so as to meet, as far as possible, the conditions which obtained in practice. It was required to compare various disinfectants on the market with regard to their germicidal efficiency; to his mind that was the only point of importance. There were other qualities in disinfectants, but he held that the destruction of pathogenic germs in all cases assumed the premier position. If they were going to standardise disinfectants, chemists would agree that one of the first requisites was that they should deal with standard reagents, and standard substances. Mr. Walker and he had found that it was possible to obtain a substantially standard organism by adopting a standard broth and growing *B. typhosus* under uniform conditions—an organism which constantly produced fairly uniform results. With regard to the addition of organic matter, he had listened with interest to Mr. Blyth's experiments on milk, and had considered the question of fat. No doubt fat in milk did diminish the coefficients of a number of coal tar products, but he did not know that milk would ever come before them for disinfection. Moreover, the fat in milk differed so much chemically, physically, and biologically, from fæcal fat, that he was not prepared to accept milk as a substitute for fæces. He did not think it possible to get any form of fæcal material of even an approximately uniform composition. Until something definite was known about the effects of such bodies as mucin, gelatin, blood, and any other substances which could be obtained in the simplest form possible by experiments of the type Mr. Blyth had described upon the coefficients of the coal tar products, they were not in a position to adopt a standard material. Mr. Walker himself, and Dr. Kenwood had protested against the employment of fæces. In a particular typhoid stool there were often sloughs and portions of intestinal mucous membrane, and in another there might be a large hæmorrhage resulting in coagulated blood, but nothing in milk would represent such conditions. The same must be said of certain dysentery stools containing 90 per cent. of mucin. To apply principles of disinfection, based on experiments with milk, to such conditions as these, he could not accept.

Mr. A. R. LING said the author had left the matter quite open as to the selection of a method, giving data on which work could be continued and a method elaborated. Many of the preparations on the market were more or less of equal merit as disinfectants, consisting as they did of tar acids and bases, and the fact that they were brought closer together when organic matter was introduced into the bacteriological test, appeared to him to indicate that the author was proceeding on the right lines, and he certainly deserved the thanks of manufacturers.

Mr. AINSLIE WALKER said he was afraid that the procedure advocated by the author was scarcely calculated to advance the movement in favour of standardisation; this procedure, quite apart from the impossible material used as a source of organic matter, was one which, in his opinion, could yield no uniformity of result from day to day, even in the hands of the same investigator. Then as regards the use of milk, if the introduction of organic matter was designed to make the conditions of the test resemble more closely those known to exist in practice, why suggest milk? Any attempt to reintroduce the now universally discredited "thread" method was to be deprecated. Von Gerlach referring to results obtained on transferring the medicated threads to sub-culture tubes had admitted that "he had to ascribe the absence of growth to insufficient washing of the threads, as subsequent inoculation with vigorous cultures proved": and anyone familiar with the structure of the silk cell would appreciate the difficulty of attempting to eliminate the inhibiting action of the disinfectant absorbed by capillarity, without washing away the coating of bacterial emulsion.

Mr. G. C. JONES asked the author to accentuate one sentence in the paper. He had made the astonishing assertion that this question of the standardisation of products which were sold in this country to the value of many thousands of pounds annually had been referred to a committee on which there was no representative of the commercial side.

Mr. R. ORCHARD wrote:—"The employment of such objectionable substances as normal fæces would militate against the general adoption of any standard method involving their use—fæces requiring disinfection are usually abnormal; but Mr. Blyth's suggestion that they can be replaced by a mixture of whole and separated milk is very valuable for experimental purposes It does not appear easy, however to obtain a standard sterile milk, and the fat, which the author considers a most important factor, is its most variable constituent. In so far as bacteria are protected by the presence of fat, it is obvious that phenol and tar disinfectants are more valuable, as they are able to penetrate a fat envelope. The Rideal-Walker method was devised, I believe, as a primary sorting test, to include all classes of disinfectants, and as the possible basis of some legal control over their sale. The introduction of large quantities of organic matter into the test at once defeats this object by eliminating a number of valuable germicides, including some capable of destroying spores which resist most of the 'coal-tar' disinfectants. It is difficult to agree with Dr. Kenwood that permanganate is the disinfectant *par excellence* by the Rideal-Walker test, as the amount of organic matter present in this method (1 drop of broth per c.c. of diluted disinfectant) is sufficient to render inert very dilute permanganate solutions. From Mr. Blyth's results with *B. coli* and potassium permanganate (Table V.) the coefficient would appear to be about 25; many substances give far higher coefficients, as, for example, chlorine—220. It should not require any elaborate bacterial test to demonstrate that permanganate will not sterilise large quantities of organic matter. If disinfectants were solely prepared to be thrown down the drains, there might be an advantage in testing them in presence of large quantities of sewage matter."

Major C. G. FOWLER wrote that he was in agreement with the general tenor of Mr. Blyth's views regarding the importance of introducing organic matter in the standardisation of disinfectants, and such a procedure had been carried out in the Army Hygiene Laboratory during the past two years in the routine examination of disinfectants. The phenol coefficient was first obtained with a stock laboratory culture, such as the *B. coli communis*, and the result was then checked by standardising against natural bacteria, such as the *B. coli communis* in fæces. He thought, however, that the author was adding too much organic matter, and, by so doing, was losing the real relative value of the various disinfectants. By making use of such strong emulsions of fæces and whole milk, the method put forward practically brought all disinfectants into one line, and surely this was not the object to be aimed for. Mr. Blyth criticised the method used by the writer when working with an emulsion of fæces (5 per cent.) in urine, and coarsely filtering, by saying that the filtrate was little better than simple urine. But the emulsion of fæces, as used by Mr. Blyth, was little better than lumps of fæces. However carefully the emulsion was ground, it was quite impossible to get rid of lumps, perhaps not perceptible to the naked eye, but most obviously present on a coarse microscopic examination. Imagine each or any of these lumps to contain several hundred bacteria within and without their substance, and the certainty of action of any disinfectant upon them was altogether obscured; and, again, what an element of chance must enter into the fishing out of the mixture with the platinum loop. The method of coarsely filtering was crude enough, but surely the use of such unfiltered and richer material was open to more serious error. Again, when employing whole sterilised milk, was it possible to use it without encountering lumps, unless homogenised? The figures brought forward with regard to the action of separated and whole milk in reducing the

coefficient figure were in agreement with his own experiments, but those obtained when dealing with a fæcal emulsion were widely different. Moreover, a 5 per cent. filtered emulsion of fæces was amply sufficient to bring down the false figures, obtained with a pure culture in distilled water, of such disinfectants as mercuric chloride, permanganate, iodine and chlorine compounds. The presence of organic matter was not by itself the only reason why the coefficient of a disinfectant might show variation. The greatest claim for the use of such material as fresh fæces was the fact that it contained organisms in their natural condition and environment. The action of a disinfectant might be quite different on an artificial laboratory culture to that on bacteria in their state of nature, this being the condition under which practical disinfection was required. The constitution and covering of the natural bacteria might so vary from that of the laboratory culture, as to offer a very different task for the action of a disinfectant, putting aside the presence of organic matter. To the question, which the author pertinently asked at the conclusion of his paper, on the practical utility of the "drop" method as a means of standardising disinfectants, he would most emphatically answer in the affirmative. After several years' trial, it was his opinion that, used in a common-sense manner and by an expert, the "drop" method of standardising disinfectants was thoroughly trustworthy, but reliance must not be placed on one kind of examination only. Firstly, the pure culture coefficient must be ascertained, followed by its trial of constancy against natural bacteria in the presence of organic matter, but the amount of this latter must certainly be limited. He was interested to observe that the figure obtained by the "thread" method was in exact accordance with that found in his own experiments working on entirely different lines.

Mr. M. WYNTER BLYTH, in reply, said he quite agreed with Dr. Martin that fæces was far better than milk, if they could get it to give good results. In standardising disinfectants with organic matter the fat must be taken into account. Plenty of substances contained fat, but if the observer avoided fat, standardising with organic matter would not be worth more than the Rideal-Walker method in water. The fact that these disinfectants were separated by the Rideal-Walker method was the great objection to it, because it was a false separation; further, its use as a commercial standard was cutting out of the market, he believed wrongly, old-fashioned disinfectants containing large quantities of carbolic acid or cresylic acid, which gave in organic matter, or matter containing abnormal or normal fæces, the same or nearly the same efficiency value as in water. It was not always required to disinfect fæces, but many varied matters. He quite agreed that it would be as well to start this problem at the other end, and, instead of taking complicated bodies like milk or fæces, to take simple bodies and work them out; but in the meanwhile the Rideal-Walker values were being used commercially, and one of his main objects was to call the attention of buyers of disinfectants on the Rideal-Walker figures to the fact that the presence of organic matter caused the values to drop enormously. He wished to reiterate the fact that this was not in any way an attack on the work of Messrs. Rideal and Walker, but only on the uses to which it had been put. He quite agreed with other speakers that theirs was a most admirable method, and hoped they would make further experiments, in which they would introduce large quantities of organic matter and fat.

Mr. WYNTER BLYTH wrote, in reply to Mr. Orchard:—"The variations in the composition of normal and abnormal fæces, as well as in the other organic mixtures requiring disinfection makes it essential that the bottom limit to which we can force the germicidal value of a disinfectant by the introduction of fæces or artificial faces should be known. It is easy to get a standard milk; all that is necessary is to get a normal milk rich in fat and break it down by the addition of separated milk. I quite agree that the coal tar disinfectants are valuable, but their value is not indicated by the Rideal-Walker figures."

"In reply to Major Fowler, the introduction of a large amount of organic matter does not by any means bring all disinfectants into one level line, and if it did it would not matter, for if two things are equal why call them unequal? On reading my paper Major Fowler will see that his remarks as to lumps and embedded bacteria are not applicable.

"The portion of my paper which dealt with organic matter is an attempt to study the influence of organic matter upon germicidal value, apart from any variations in the organism used. On this account a pure culture of a definite organism was taken. I fully recognise that natural bacteria have not the same resistances as laboratory cultures; unfortunately in a standard test the first necessity is a standard organism, which, it requires no argument to prove, cannot be a natural fæcal organism."

THE DETANNISATION OF SOLUTIONS IN THE ANALYSIS OF TANNING MATERIALS.*

BY DR. J. GORDON PARKER AND H. GARNER BENNETT, B.SC.

(Contribution from the London Leather Industries Laboratories, Herold's Institute, London.)

If there is any point upon which the members of the International Association of Leather Trades' Chemists are perfectly agreed, it is that the present official method of detannising solutions for analysis (*i.e.*, the use of unchromed hide-powder in the filter bell) is extremely unsatisfactory. In order to meet with these difficulties, various proposals have recently been made to modify the present system of analysis, but notably by Dr. J. Paessler (Collegium, 1906, 234—236) and by Mr. F. Kopecky (Collegium, 1906, 199—203). The former proposes the use of a lightly chromed hide-powder of his own manufacture in the filter bell, whilst the latter advocates a heavily chromed and neutralised powder of his own preparation, used with a definite quantity of acetic acid, and with a maceration method. It seemed desirable that the claims of these two powders should be investigated by others than the makers of them, and hence the authors proceeded to do a series of comparative analyses, the same extracts being analysed by the official method and by the methods of Paessler and Kopecky, using powders prepared by them. The results of these analyses are shown in the tables below.

It has long been recognised that hide-powder is capable of absorbing many non-tannin substances, and hence it is clear that as long as tannin is estimated gravimetrically by the difference between the amounts of "soluble solids" and "soluble non-tannin matters," the most correct result will be that which yields the highest percentage of "non-tannins," so long as the residue is proved free from tannin and soluble hide substance. With the various chestnut and oakwood extracts first used, the method of Kopecky appeared to be very promising, being convenient to work, and giving, as the figures show, distinctly higher results in non-tans. When, however, tried upon a hemlock extract, even with the increased amount of hide-powder recommended by Kopecky (40 grms. wet), the non-tannin filtrates clearly contained tannins, and this tannin was not removed even by extending the time of maceration for another hour. This is also evident in the results obtained.

The same difficulty occurred later in the analysis of quebracho extracts by this method, the non-tannin filtrates when tested with a 1 per cent. gelatine, 10 per cent. salt solution, showing at once the presence of a considerable amount of tannin.

Further, in the analysis of various sulphited extracts by Kopecky's method, it was clear that something was wrong. As Kopecky's powder is neutralised, it is necessary to add acid to the solutions for analysis, and its maker recommends the use of 5 grms. of acetic acid per litre. This acid causes complications which are very obvious in the detannised solutions. As soon as the solutions are pipetted off and the evaporation commenced, the

* Taken as read.

liquids begin to show a darkening of colour, first deep orange, then brown, and finally black. After adding 50 c.c. of distilled water and evaporating again to dryness (as Kopecky suggests for driving off the last traces of acetic acid), this colour was intensified. This blackening also occurred with the undetannised solutions, though their first colour made the change less obvious. What is the exact cause of this phenomenon is a little difficult to state. Kopecky, in writing to one of the authors upon inquiry, suggested that the blackening was due to "traces of iron which oxidises and forms blacks with the traces of gallic acid always present in non-tan filtrates," the oxidation becoming possible when the sulphur dioxide is driven off by the action of acetic acid, or that some "sulphuric acid or bisulphates might be present in the extract which would cause the residues to char." Both these suggestions seem rather improbable. Other suggestions to account for this are that the acetic acid acts upon the sulphite compound in the extract, driving off sulphur dioxide, and forming sodium acetate, which, acting upon the tannin and phenolic non-tannin bodies, caused oxidation and blackening; or, that the acetic acid dissolves out chromium from the powder (see below), partly, at any rate, as chromium acetate, which acts upon the tannin and phenolic non-tannin matters, producing readily oxidisable compounds. It is quite possible, of course, that both these, and other causes not suggested, might combine to produce the effect noted. Whatever the cause, however, it is clearly undesirable to use solutions acidulated with acetic acid for the analysis of sulphited extracts. It should be mentioned, perhaps, that even the sulphited extracts were not completely detannised by Kopecky's powder

It will be noticed at once that in all these cases, and in all the previous work, the results given by Paessler's powder are lower in the percentage of non-tannins, the usual difference being about 1½ per cent., though sometimes as great as 4 per cent. They are, therefore, even further divergent from the real truth than the analyses by the official method with the use of unchromed powder. This is extremely unfortunate, for Paessler's powder is a distinct improvement upon the unchromed, in both the packing of the filter-bell and in the rapidity with which the tannin solution soaks up the hide-powder. Such minor improvements, however, are quite overshadowed by the unfortunate readiness with which this chromed powder absorbs the non-tannin matters, which causes the percentage of tannin to be recorded much higher than it really is. As we know our present official method to be defective in that the powder absorbs non-tannins as well as tannins, it would clearly be very undesirable and unwise to modify it by the replacement of unchromed powder (bad as it is) by the powder of Dr. Paessler.

As is well known, the filter method rejects the first 30—35 c.c. of the filtrate in order to eliminate as far as possible the error due to soluble matter in the hide-

powder. This error is not completely eliminated in this way, however, and there is no doubt that the soluble matter from the hide-powder, being weighed along with the non-tannin matter, tends to raise the percentage of the non-tannins, and incidentally make the result more correct. Now, with a chromed powder it is known that the soluble matters are usually less, and it appeared desirable to find out how far the variations observed between chromed and unchromed powders could be accounted for by a difference in solubility. That this could only partially explain the difference in the percentage of non-tannins commented upon above, was clear from the variations in the extent of this difference; it being influenced, no doubt, by the nature of the non-tannin matters in the various extracts analysed.

The authors, therefore, proceeded to do "blank" tests with each of the powders, first with distilled water only, and afterwards with ½ per cent. acetic acid, which is the concentration necessary in the analysis by Kopecky's method. It was thought desirable to include here experiments with Miller's cellulose-free hide-powder, chromed and used as in the American official method. In each case 50 c.c. were pipetted off and evaporated just as in the course of the usual analysis by each of the methods. The results are stated in the tables below:—

A.—*Solubility of powders using distilled water.*

	Residue in mgrms. A.	B.
1. I.A.L.T.C. unchromed powder—		
Experiment 1	4·4	4·5
,, 2.	5·0	5·0
,, 3.	6·5	6·6
2. Kopecky's powder—		
Experiment 1.	1·1	1·1
,, 2.	1·6	1·7
3. Paessler's powder—		
Experiment 1.	3·3	2·3
,, 2.	3·6	3·7
4. Miller's powder (A.O.A.C.)	3·7	3·7

Solubility of powders using ½ per cent. acetic acid.

	Residue in mgrms. A.	B.
1. I.A.L.T.C. unchromed powder	Powder swells too much to allow the filtration.	
2. Paessler's lightly chromed powder		
3. Kopecky's powder	6·0	6·0
4. American shake method	1·6	1·9

The results of Table A confirm the view that Paessler's powder, though less soluble than the unchromed, is not sufficiently so to account for the difference in the percentage of non-tannins found in the comparative analyses, and hence that this difference must be accounted for by the absorption of more non-tannins in the case of the chromed powder. Kopecky's powder is shown to contain much the least quantity of matter soluble in distilled water.

The results of Table B confirm what has been previously observed as to the difficulty of working in the filter-bell with acid solutions. In the case of Kopecky's powder the results were unexpectedly high, the increase being evidently due to the solvent action of the acetic acid. The residues were bluish in colour, and when re-dissolved in a small quantity of distilled water answered the ordinary qualitative tests for chromium and sulphate. It is clear, however, that in the analysis of an extract the worst error due to solubility will occur in the analysis by Kopecky's method.

The authors now turned their attention to the analysis of tanyard liquors, comparative detannisations being made by the various powders and methods. The results are stated below. In the first three tables the powder used for the analysis by Kopecky's method was freshly prepared by one of the authors, following directions of Kopecky, and was used in the shake machine. In Table 4, powder of Kopecky's own make was used, with his maceration method, and in each case the liquor was incompletely detannised.

Tanyard Liquors.

Method.	Non-tans per cent. 1.	2.	3.	4.
1. A.O.A.C.	5·7	5·8	7·1	5·7
Paessler	4·0	5·6	6·4	4·0
Kopecky	3·2	4·9	6·0	3·2
2. A.O.A.C.	3·9	4·8	6·9	7·8
Kopecky	3·4	4·2	6·1	6·4
3. I.A.L.T.C.	2·5	3·0	3·1	—
Kopecky	2·3	3·0	3·5	—
4. Kopecky	5·6	7·7	5·5	—
I.A.L.T.C.	5·4	6·6	5·4	—
Paessler	5·1	6·3	5·2	—

The figures show up again emphatically the immense superiority of the American shake method over the filter-bell methods in the matter of used liquor analysis, and at the same time confirm the contention of Kopecky that his neutralised powder will not give good results unless the residues are re-dissolved, and corrections made for the free acid, in the way suggested by Professor Procter ("Leather Ind. Lab. Book," 126). This process, if made into an official decree, would make the analysis of liquors a very tedious business, and involve almost more labour than is justified by the value of the results. In a well-regulated tannery, however, the acidity is kept approximately constant at different stages, and the difficulty might be overcome by making an average correction which should be checked every few weeks in the manner suggested.

The advantages of the American shake method again came out strongly in the analysis of used liquors which were known to contain practically no tannin. The analyses are as follows:—

Spent Tanyard Liquors.

Sample I. Total solids 4·5 per cent.

Method.	Non-tans. per cent.	Tannin. per cent.
A.O.A.C.	4·5	0·0
I.A.L.T.C.	3·7	0·8
Kopecky	3·6	0·9
Paessler	3·5	1·0

Sample II. Total solids 3·7 per cent.

A.O.A.C.	3·6	0·1
I.A.L.T.C.	2·9	0·8
Kopecky	2·6	1·1
Paessler	2·4	1·2

Sample III. Total solids 3·4 per cent.

A.O.A.C.	3·4	0·0
I.A.L.T.C.	2·8	0·6
Kopecky	2·6	0·8
Paessler	2·5	0·9

The above shows most emphatically the absolute superiority of the A.O.A.C. method for the analysis of sour tanyard liquors, and the I.A.L.T.C. are to be congratulated on having adopted this method for that purpose; it also shows how inaccurate and misleading are the results obtained by Paessler's method, as all the above liquors were completely denuded of all tannin properties before analysis.

The use of unchromed powder being rejected as bad, and having found that the two methods which were proposed to supply its place were worse; and as the American shake method was already the official method even of the I.A.L.T.C. for used liquors, advisable for extracts, etc., containing quantities of gallic acid, and permissive always; it will be readily understood that the authors became at once very strongly inclined to urge the acceptance of the A.O.A.C. method of detannising in all cases, and to make it the official method of the I.A.L.T.C. This, of course, is not by any means a new recommendation to the I.A.L.T.C., being, in fact, proposed by Professor H. R. Procter at the Leeds Conference of 1902. The pity is that it was not accepted then. Now it is the only course left.

The superior accuracy of this method has been repeatedly demonstrated both by Americans and by members of the I.A.L.T.C., and the work of the present authors fully confirms this view. Even the analysis of the following few tanning materials makes this quite clear.

1. Solid Quebracho Extract (A).

Total solubles 71·8 per cent. Insolubles 7·5 per cent.

Method	Non-tannins. per cent.	Tannin. per cent.
A.O.A.C.	10·8	61·0
Kopecky*	10·3	61·5
I.A.L.T.C.	6·5	65·3
Paessler	6·1	65·7

2. Solid Quebracho Extract (B).

Method	Non-tans. per cent.	Tannin. per cent.
A.O.A.C.	16·6	22·2
I.A.L.T.C.	16·2	22·6
Paessler	15·0	23·8

5. Hemlock extract.

Total solubles 46·8 per cent. Insolubles 2·7 per cent.

Method.	Non-tans. per cent.	Tannin. per cent.
Kopecky*	24·6	22·2
A.O.A.C.	21·3	25·5
I.A.L.T.C.	17·0	29·8
Paessler	16·0	30·8

* Incompletely detannised.

The rest of the work in this investigation consisted in the detannising of artificial mixtures of tannin and non-tannins, in various proportions, by all the four proposed methods. This method of working had already been used to some extent by Procter and Blockey (Collegium, 1903, 114 and 124) for comparative work on the two "official" methods. In the present work, however, the same amount (4·5 grms. per litre) of a sample of commercial "pure" gallotannic acid was used every time, and the quantities of the soluble non-tannin matter added were gradually increased from ½ grm., 1 grm., 1½ grms. to 2 grms. per litre. The method of calculating results was the same as is used by Procter and Blockey. The first column gives the weight of matter used for each experiment and the weight of residue from 100 c.c. (twice 50 c.c.) evaporated, from which the dry, or at least the non-volatile matter, can obviously be calculated. The "Total Soluble," the "Tannin," and the "Non-tannins" are given in percentage of the dry total soluble of the tannin employed, and obviously in each case the effect of the added non-tannins will be obtained separately by deducting the corresponding figures given by the determinations of the tannin alone by that particular method of analysis. The fifth column gives the difference between the amount of tannin estimated in the "pure" sample and the amount shown after the addition of the non-tannin substance. The last column gives the proportion of the added non-tannin substance estimated as tannin by the respective methods, calculated on the actual dry non-tannin matter in excess of the 100 per cent. reckoned for the "total soluble" of the "pure" tannin. Each of the "non-tannin" filtrates in all these experiments are tested with a 1 per cent. gelatine 10 per cent. salt solution, and in every case where Kopecky's method was used the presence of tannin was revealed, showing incomplete absorption by the powder, but this was observed in no other case.

Table I. gives the analysis of the "pure" tannin by each of the four methods, and Table II. gives the results for the mixtures of tannin with gallic acid.

The analyses by the official method with unchromed powder show up the long-known errors due to the absorption of gallic acid by the unacted-upon hide-powder in the upper part of the filter-bell. Curiously enough, the proportion of the gallic acid present absorbed in this way appears to be approximately constant. The analyses with Paessler's powder all show a higher amount of tannin than in the case of the official method of the I.A.L.T.C., and also reveal the fact that the proportion of the added gallic acid absorbed is decidedly more marked.

In the Kopecky analyses the added gallic acid appears to make his powder absorb tannin even less readily, so that after the gallic acid is added less "tannin" is recorded than before, and hence negative quantities appear in the fifth and sixth columns. As the proportion of gallic acid is increased, however, these negative figures decrease, and finally become increasingly positive, pointing to the conclusion that the powder absorbs gallic acid in considerable quantities, and that this error finally overwhelms the other.

In each case of analysis by the A.O.A.C. method, the results show up much the best, in that they are always nearer the real truth, and also that the proportion of the added gallic acid estimated as tannin is much smaller. This confirms the work of Reed (American Leather Chemists' Journal, 1906, 288).

Table III., giving the results obtained with mixtures of tannin and dextrin, show up again the errors due to the absorption of non-tannin matters by the filter-bell methods, which errors are greater in the case of Paessler's powder. It is observed, however, that as the proportion of dextrin is increased, the percentage of it estimated as tannin is decreased. The reason for this is not very obvious, but it may possibly be connected with the method of rejecting the first 30 c.c. from the filter-bell, or may possibly be partly accounted for by the influence of varying quantities of dextrin on the absorption of the other non-tannin matters present as impurities in the sample. In the Kopecky analyses, we have incomplete absorption, and hence also irregular variations on the results, illustrated by the uncertain extent on the negative values in columns 5 and 6. The American method shows that very little dextrin is absorbed, whatever the proportion of it present, and the results are a strong justification of the A.O.A.C. method of detannising.

Table IV. gives the results with the various mixtures with glucose. The filter-bell methods again show their usual position in the amount of tannin estimated both with regard to one another and to the shake method. It will be noticed that as the glucose increases in amount, negative values are recorded in the last two columns, and as this is not due to the non-absorption of tannin, it is an interesting confirmation of the observations of Procter and Blockey as to the solvent action of carbohydrates on hide-powder. With Paessler's powder this solvent action is distinctly more marked. With Kopecky's method we find here again incomplete absorption, and along with the solvent action of the glucose, we find tremendous negative errors of an irregularity which might be expected.

The A.O.A.C. method again shows up strongly in a very favourable light, the error being always extremely small and not increased with the increasing proportion of glucose to tannin.

Table V. illustrates the effect of increasing quantities of calcium acetate. Here we notice at once that all the values in columns 5 and 6 are decidedly negative. It was observed, too, that in all residues (both "solubles" and

"non-tans" from all the methods) were intensely dark coloured. The explanation of these facts is not far to seek. The presence of calcium ions and tannic and gallic acid ions (in the non-tannin filtrates of gallic acid ions only) results in the formation of calcium tannate and gallate, which readily oxidise when their aqueous solutions are evaporated at steam heat, producing those dark-coloured products of unknown composition which are familiar to those who are accustomed to the analysis of suspender liquors. It is possible that these products may have lost some of their carbon in volatile decomposition products, which may partly account for the decreased amounts of tannin recorded; but it is equally possible that this may also be partly accounted for by the fact that the formation of calcium tannate and gallate, being a double composition, involves the formation of acetic acid which also volatilises, and hence that all the matter added is not weighed, and consequently the amount of tannin appears to have decreased.

In this table the more significant column is that which shows the decrease in the amount of tannin estimated, as in that case the figures obtained depend more directly upon the non-tannin results, which, being affected only by the presence of gallic acid, should have an approximately constant error, for the quantity of gallic acid cannot vary much. Strictly speaking, only the results for one definite mixture are comparable, because in the estimation of the "total soluble" we have also the error due to the oxidation of calcium tannate, which varies with the quantity of calcium acetate added, and which will not be approximately constant until calcium acetate is in excess As each molecule of the tannin of gallotannic acid (containing six hydroxyl groups) will require 3 molecules of calcium acetate (shown by Procter and Bennett, this J., 1900, 251—254), 1 grm. of tannin would require 1½ grms. calcium acetate for excess of the latter, and this proportion is never reached in the above experiments. It is quite possible, however, that this variation in error has a small influence on the comparative value of the figures and may be left out of consideration.

The analyses with Paessler's powder again reveal a greater amount of tannin than that estimated by the I.A.L.T.C., and, as the tannin figure is low because of the oxidation phenomenon, by a compensation or errors Paessler's powder shows a less percentage error. In the analysis of liquors, therefore, Paessler's powder would tend to give a result nearer the actual truth, because of its tendency to absorb "non-tannin" matters, but it is scarcely to be recommended on that ground.

Table VI. gives the results for the mixtures with calcium lactate. In this case the observations were almost precisely similar to the mixtures with acetate of calcium; the residues were black and oxidised, and the "difference in tannin estimated" is again a negative quantity. With calcium acetate the extent of this is not so great, but this can be readily understood when we remember the tardiness with which lactic acid volatilises. There again, after allowing for the factor of oxidation, we see that the A.O.A.C. method is very much better than that of the I.A.L.T.C., and that Paessler's method is very much worse, Kopecky's being really out of the question on account of the uncertain amount of tannin left unabsorbed.

Table VII. gives another series with the use of Epsom salts. Once more the "difference in tannin estimated" is usually a negative quantity. This was rather surprising, for the metal of the salt is combined in this case with a strong acid radical, which would prevent the formation of any magnesium tannate or gallate. It is known, however, that tannin is capable of combining with some metallic salts, so that the acidic radical as well as the basic is taken up by the tannin molecule, and it is possible that the decrease in the amount of tannin recorded may be accounted for by the conversion of the gallotannic acid into some such "non-tannin" compound. This point, however, needs further investigation.

In this series also we notice that the American method gives results not only lower in tannin than the other methods, but much nearer the actual figure obtained by the analysis of the gallotannic acid alone, as shown in Table I.

Table VIII. shows the results obtained by the use of common salt as the added non-tannin substance. The analyses by the American method all show practically the same tannin content as before the addition of salt, which is extremely satisfactory. The filter bell methods reveal again a decreased amount of tannin after the addition of salt, and this decrease is approximately the same for each proportion of salt. What this is due to, is not exactly clear. It cannot be analogous to the case of calcium acetate, for the acidic radical of sodium chloride is too strong to allow of the formation of sodium tannate or gallate, and moreover no blackening was observed in the residues, as would be seen if there had been oxidation to any great extent. That common salt and tannin combine as a whole seems unlikely also. It is well known that salt solutions have a distinct solvent effect upon part of the hide-substance, and this, of course, would increase the non-tannins and lower the amount of tannin recorded; but the lowering observed is of such an order as to make it doubtful whether this can be the sole explanation of the negative values observed, especially when we bear in mind that the concentration of the salt is not large. Whatever the cause, however, it is clear that the results are a splendid justification of the American shake method. The amount of tannin shown is always greater for Paessler's chromed powder than by the official unchromed, which is readily explained by its greater absorption of salt, shown also by the lower negative values in the last two columns. The Kopecky analyses again showed incomplete absorption of tannin.

Table IX. gives analysis of sodium bisulphite mixtures. The amounts of tannin recorded are again less than before the addition of bisulphite, this being obviously due to expulsion of sulphur dioxide and consequent lowering of the "total soluble" percentage. As in the case of calcium acetate, this error will alter with the proportion of bisulphite used, so that only the results for one definite mixture are strictly comparable. In any mixture, however, it is clear that the American method gives the least error. In the Kopecky analyses the error is much intensified by the presence of the acetic acid essential to his method, and hence huge negative quantities appear in the last column. This again emphasises the undesirability of acidifying the solutions in the way suggested by him. It was also noticed that in all these analyses the non-tannin filtrates contained appreciable amounts of chromium.

The above experimental work has placed the authors in close familiarity with the working of each of the three proposed methods mentioned above, and they are, therefore, in a position to pass some judgment upon each.

1. *Kopecky's powder and method.*—In this case one can scarcely believe that the powder was in the same condition as when freshly made, or as it was used by Kopecky himself. The loss in absorbency was clearly due to the fact that the powder after being kept some time would not wet back, even with 24 hours' soaking. This can no doubt be partly accounted for by its being so heavily chromed, though possibly the neutralisation of the powder may act in this direction also. It is extremely disappointing to find this cheap source of a workable hide-powder cut off in this way, but it is hardly surprising when we remember the previous disappointments in various American attempts to prepare a dry chromed hide-powder that will keep.

The use of acidified solutions, which is necessary in the case of a neutral powder, has also been shown to be objectionable, more especially in the case of treated extracts, and if this course were to be finally chosen it would be obviously necessary to reduce the quantity of acid to a minimum. The quantity advocated by Kopecky (5 grms. per litre) seems altogether too large. Moreover, the addition of acetic acid to the solution of the extracts before making up to mark is open to strong objections from other standpoints, such as the action of the acid on the tannin, which makes quite an appreciable difference in the amounts of "total solids" and "total solubles" estimated, and also its effect upon the quantity of "Insolubles" and upon tintometer readings. On the other hand, the addition of acid just before detannising involves another correction.

2. *Paessler's powder and method.*—As the method consists in the use of the filter-bell, it is open to all those strong objections which have been repeatedly urged

against that method, and which have been once more emphasised in the results of the analyses in this investigation. Dr. Paessler has also had the misfortune of making a powder which, though in some respects an improvement upon the unchromed, possesses a decidedly more marked affinity for "non-tannin" matters, which feature is just the one that it is most strongly desirable to avoid. Again, the keeping properties of this powder have not been tested thoroughly, and in view of the difficulties already observed in preparing dry chromed hide-powders which will remain constant in quality, it is exceedingly important that this should be done before its adoption as an official powder.

3. *The American method.*—There can be no doubt in this case that the method is workable and reliable, for it has been very thoroughly tested by both American and European chemists.* In comparison with the other methods the authors find that it stands in an exceedingly favourable position. It is the easiest to work, the soundest in principle, the most accurate in its results, and duplicate experiments will always agree. Moreover, in spite of the supposed trouble in preparing the powder, the authors find that it is decidedly the quickest to work.

There can hardly be much difference of opinion as to the conclusions to be drawn from the above facts. It is perfectly clear that the I.A.L.T.C. cannot with any wisdom accept either the methods of Dr. Paessler or of Mr. Kopecky, and it is equally clear that the American method of detanning is much superior to our present method. The authors, therefore, very strongly urge that the International Commission which is now at work upon this question should recommend the adoption of a uniform and universal method, which should be on the lines at present used by the American Leather Chemists' Association.

In conclusion, the authors desire to thank Mr. D. Stewart, M.A., and Mr. A. T. Hough for assistance rendered in doing some of the analyses in this investigation.

Manchester Section.

Meeting held at Manchester on Friday, November 2, 1906.

DR. G. H. BAILEY IN THE CHAIR.

REMARKS ON THE WORK OF THE SECTION.

The Chairman referred in some detail to the activity that was being displayed in developing new products, and hoped that communications might be made to the Section by those directly engaged in manufacture more freely than hitherto. He then supplemented these earlier remarks by touching upon some questions of general interest to all branches of chemical industry. From time to time the united efforts of the Sections had been devoted to the discussion of such matters as river pollution, technical education, sampling, patent laws, traffic rates, and means of transit for goods. But in cases where the information was required in support of public measures of reform, it was manifest that this want of completeness and the delay which occurred in getting together the necessary detail acted very prejudicially. Thus in regard to more ready and cheaper methods for the transit of goods, which had occupied the attention of a Committee of the Council for some years, there was surely no reason why it should not be part of the ordinary business of this or any other Section to constitute itself a medium for collecting information. In this way the necessary details would be ready to hand when called for, and with the further great advantage that, after preparation by a Committee of the Section, they might be thoroughly sifted and discussed before a meeting of the members. Any question affecting the relations of their industry with local or imperial authorities was capable of being so treated.

Dr. Bailey then considered the question of sampling in its various applications in order to indicate that even with such a topic there were many points which might with advantage receive further attention from the Section.

He had chosen sampling as an example of the complexity and the many-sided character of an operation of wide application. Any of the other questions touched upon would equally serve to show how essential it was to recognise the manifold conditions which surround science in its application to industry. The experience of any one branch of chemical industry, or even of several, however important or however well represented, could not suffice, and we were brought to realise how necessary it was that full use should be made of the opportunity of securing a sufficient array of facts and ample discussion, and of bringing together for this purpose representatives of all the branches of industry concerned.

It was also manifest that the chief responsibility in bringing about a satisfactory issue rested upon those actually engaged in manufacturing operations.

Moreover, it was only by the adoption of such means

that a satisfactory *modus vivendi* could be arrived at as between manufacturers and the local or imperial authorities, with whom they desired to work in amicable relation.

This was indeed one of the most important problems now in front of chemical industry, and its effective solution was urgently called for.

A GRAPHICAL METHOD OF RECORDING THE WORK OF VITRIOL CHAMBERS.

BY W. H. COLEMAN.

When looking at the daily report of the work of a set of vitriol chambers it is not easy to tell at a glance how it compares with the previous reports, and I have found the method about to be described very helpful in judging the history of the plant, with the view of giving such instructions as may serve either to remedy a defect in the working, or to increase, if necessary, the work done. The method adopted consists in plotting on squared paper the results of certain daily tests and data concerning the plant; the results chosen have been arrived at after considerable thought, and form a record of those facts which it is most important for the vitriol plant manager to keep in view. The method has been in use for about 18 months, and, for the sake of illustration, a diagram is given of the curves plotted during the months of September and October, 1905. The curves are classified into two series, and in the actual records they are drawn in different coloured inks to render them more distinct, but in the diagram different kinds of lines have been used. The horizontal line represents the days, and the vertical lines are numbered in the upper series so that each small division represents 2, and in the lower series 1 unit or decimal part, as the case may be.

On the upper half of the sheet are recorded daily: -

Curve I.—In black, (.-.-.-.-.-) the cubic feet of chamber space per lb. of sulphur charged per 24 hours; the figures represent units.

Curve II.—In red (· · · · · · · · · · ·) the percentage of nitre used on the sulphur charged; the figures represent tenths.

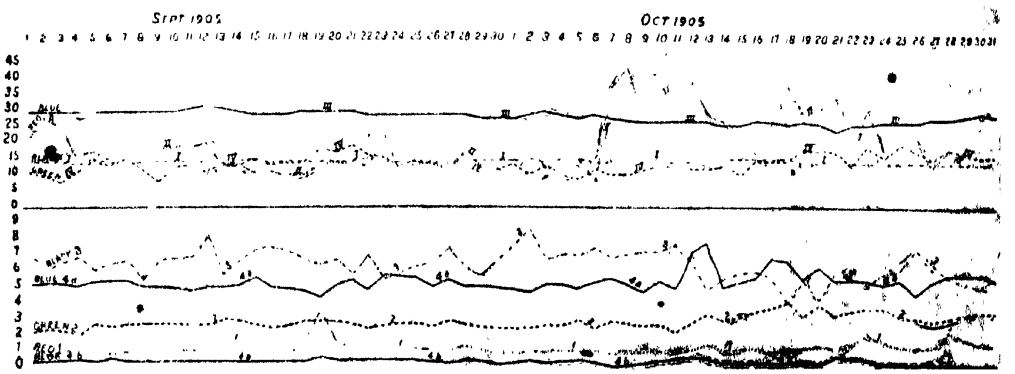
Curve III.—In blue (— — — — —) the total dip of acid in the chambers, that is the sum of the dips of the separate chambers; the figures represent units.

Curve IV.—In green (- - - - - - - - -) the daily average difference in temperature in degrees Centigrade between the gases entering the first Gay Lussac tower and the air; the figures represent units. On the lower half of the sheet are recorded daily: -

Curve 1.—In red (· · · · ·) the number of grams per cubic foot of total acids calculated as SO_3 in the exit gases.

Curve 2.—In green (- - - - -) the percentage of carbon dioxide in the exit gases.

Curve 3.—In black (.-.-.-.-) the percentage of oxygen in the exit gases.



Curve 4 *a* and *b*.—In blue (————) the number of c.c. of nitric oxide gas obtained in the nitrometer from 1 c.c. of acid from the bottom of the Gay Lussac towers, the upper blue line, 4*a*, showing the results from the first and the lower 4*b*, from the second Gay Lussac.

In all cases, the small divisions represent tenths, and the figures represent either single estimations, or the average of several taken at intervals during the day It would, no doubt, be better to draw an average daily sample of the gases and acid, and to plot the results of the tests of these average samples; but owing to the unreliability of the ordinary methods of drawing samples of gases from a main, and to lack of time to work out better methods, these figures have been used. I hope in the near future to be able to devote more time to this subject.

I do not pretend to any great novelty in the method, but as I have never seen or heard of a graphic method applied in this way, I thought that it might be of interest, and I have personally found it helpful in many ways. It keeps very vividly before one's mind not only the present but the past condition of the plant, it points out any continued carelessness on the part of the men, or any other continued source of bad or irregular work, and enables a remedy to be sought for and applied; it also creates a healthy rivalry between the chamber managers who superintend different sets, and has finally the merit of keeping the chemist himself up to the mark, as it compels attention in a way never attained by written or tabulated records, however perfect. It should be remarked that during the month of October a portion of the sulphuretted hydrogen from the sulphate of ammonia plant was burned in addition to the oxide, and as the amount varied very frequently owing to causes which have nothing to do with the acid department, this accounts for the rather rapid variations in the nitre percentage.

Some few details concerning the plant and its working may be of interest. The set consists of a row of spent oxide burners, a Glover tower, three chambers, and two Gay Lussac towers, the latter being worked in series with a Kestner fan between them. The acids are raised by automatic Kestner elevators, so arranged that the distribution of the acid is not left to the tower man, but is regulated by the chamber manager from the indications of the meters attached to the elevators, and that the whole of the weak nitrous acid coming from the second Gay Lussac tower has to be passed down the first.

The average condition of the drips, &c., was as follows:—No. 1 chamber drip 130° Tw. temperature 85° C. No. 2, 125° Tw., 55° - 70° C.; and No. 3, 95° Tw., 35° C. Temperature of the gases passing from the Glover to No. 1 chamber averaged 95° C. The acid left the Glover tower at 140° C. and 140° Tw. The acid supplied to No. 2 Gay Lussac tower was at 23° C. and 143° Tw., and to No. 1 Gay Lussac tower 30° C., and 141° Tw. These figures vary somewhat from those obtained with ordinary pyrites plants, but the manufacture of acid from spent

oxide is neither so simple nor so steady, and requires close and careful watching. As the connections between the chambers have all been constructed on the plan suggested by Mr. Porter in the paper which he read before this Section some time ago, I may perhaps be permitted to make a few remarks on the results obtained in actual practice.

There is no doubt that the capacity of the chambers is increased, and that the greater part of the work of conversion of the sulphurous acid into sulphuric acid takes place in the first three-quarters of the chamber's length. On the other hand, the conditions seem less stable, and the plant must be very carefully and closely watched for the first signs of something wrong, and the proper remedy applied at once, or it will soon get out of hand—in fact, it becomes more sensitive and responds much more quickly to alterations in the conditions of working.

Discussion.

The Chairman thought if it had been customary to express such results on curves such as those shown, we might long ago have been in a position to diagnose what was going wrong in chambers, and many phenomena which were still obscure. It struck him that the acid in the bottom of the chamber played a very much more important part in the process than had hitherto been thought of, a view which received considerable support from a comparison of the curves on the diagram.

Mr. H. Porter thought the diagrams would be a great assistance to managers, foremen, and workmen. The blue line showing the level of acid in the chambers, and the red line indicating the consumption of nitre, were exceedingly interesting. At the point where the acid line showed variation, the nitre line also fluctuated, and there would appear to be a relation between the bottom acid and the gases in the chamber. That was not a new subject, and recent observations he had made pointed to this, especially in hot weather. Mr. Coleman had mentioned the bottom inlet into chambers, which he (Mr. Porter) demonstrated before this Society three years ago, and he stated that undoubtedly they increased the make of the acid. Experiments lately had shown this, and one firm introduced the bottom inlet at an angle instead of at right angles to the chambers, with the result of impinging the gases on to the surface of the acid in the chambers, causing a rippling of the surface. This caused the liberation of the nitrous compounds from the chamber acid, and had a very marked influence on the general working, especially in hot weather.

Mr. Herbert Morris thought it would be a rather dangerous thing to draw conclusions from the lines shown upon the diagram. Mr. Coleman had not mentioned that it was very probable that the oxide used varied in its sulphur content during the period in which the tests had been carried out; this might account for very considerable variations in the lines.

Mr. Coleman, in reply to Mr. Porter, said there was no doubt that the variation in the nitre line was due, not only to the irregular supply of sulphuretted hydrogen, but also to the falling stock of acid in the chambers as indicated by the dip line. If there was one fact more than another that was important in the manufacture of acid, it was the maintenance of the stock of acid and consequently the stock of nitre in the acid of the chambers. If the capital of the plant as represented by nitre was allowed to fall, it had a very prejudicial effect upon the working. With regard to the rippling of the acid, this would cause an increased surface of the acid in the chamber to be exposed to the action of the gas with a resulting increased rate of interchange between the molecules. In reply to Mr. Morris, he said that the oxide was tested daily, and no great variation in the amount of sulphur burnt took place, which would be seen from the black line in the upper diagram, which showed the relation between the sulphur charged and the chamber space. As to the ammonia, as a matter of fact, none did pass into the chambers, and the variation in the percentage of nitre was explained, not by the fact that sulphuretted hydrogen was being burnt, but by the fact that the supply of this gas was very irregular, and caused the conditions in the chambers to be constantly changing. If everything could be kept perfectly steady and constant, the manufacture of acid would be much simpler.

THE SELECTION OF BENZINE FOR DEGREASING.

By S. R. Trotman, M.A., F.I.C.

The so-called benzine used in degreasing is a mixture of petroleum hydrocarbons of varying boiling points. Both the efficiency and economy of degreasing processes depend to a large extent upon the careful selection of the solvent. It may be taken as a general rule that the suitability of a benzine varies inversely with the percentages it contains, distilling below 80° C. and above 110° C., and directly with the shortness of the range of boiling points. The fractions distilling below 80° C. are very wasteful, owing to the difficulty of completely condensing them, and to their high vapour tension. The high boiling fractions, on the other hand, require more fuel, and are very difficult to expel from the residual grease without causing deterioration of colour, and sometimes loss of glycerin owing to decomposition of the fats. If they are left in they spoil the grease for soap making. There is, however, no doubt that the low fractions are by far the more expensive. A perfect spirit would be one having a constant boiling point of about 95° C. The value of commercial samples, in the absence of the low and high boiling fractions, depends upon the percentage distilling over within a short range of temperature on either side of this point, say from 90° to 100° C. The following are examples of good and inferior spirits (distilled by the method described below):—

Fraction distilling.	Good.	Poor.	
Below 80° C.	3·0	25·0	6·0
Between 80°—90°	12·0	33·0	14·0
" 90°—100°	82·0	16·0	33·0
" 100°—110°	3·0	14·0	26·5
Above 110°	—	12·0	20·5

The good sample will cause little waste, and contains much more spirit distilling between 80° and 90° than the other samples.

These facts make it obvious that the chief test upon which a benzine must be evaluated is a fractional distillation, with the proviso that the method employed must be capable of differentiating between the valuable and valueless fractions. This being so, it is a remarkable fact that the method of testing adopted by the trade is incapable of distinguishing between a good and a bad spirit, and is therefore, from a buyer's point of view, absolutely useless. For this test, 100 c.c. of spirit is placed in an ordinary distilling flask of about 100 c.c. capacity connected with a condenser, and is heated with a naked flame. The rate of distillation is such that the drops fall into the receiver as quickly as possible short of a stream. If the object of the test were to conceal the presence of fractions of low boiling point, it is difficult to see how a better test could have been devised. A prolonged experience of the test has convinced me that it entirely fails to distinguish between a good and bad sample from a degreaser's point

of view. The following method has for some time past been used by me with very satisfactory results. One hundred c.c. of the benzine are placed in a round bottomed flask of about 150 c.c. capacity, and having a short neck, 1 in. in length. The latter is connected to a Young's rod and disc fractionating column with 16 chambers, the distance from the neck of the flask to the lateral exit tube being 13 in. The bulb of the thermometer is placed 1 in. below the lateral exit tube. The fractionator having been connected to a condenser with adapter, the flask is placed upon a piece of asbestos with a circular hole, and heated with a shaded direct flame from a small Bunsen burner, the gas supply being controlled by a screw clamp placed on the supply tube. The rate of distillation is maintained at approximately one drop a second. The distillation is started with a flame which will produce the required rate, and its height is only altered when the temperature or rate of distillation shows any inclination to fall. The method is capable of giving perfectly consistent results. This may be seen from the following table, which gives the figures obtained, independently by three different persons, from the same benzine; the fourth column gives the results of the trade test upon the same sample:—

Fraction	1	2	3	4
Below 70° C	2·5	2·5	2·5	—
Between 70°—80°	21·5	20·5	22·0	5·0
,, 80°—90°	31·0	32·0	31·5	45·0
,, 90°—100°	23·0	23·5	22·0	35·0
,, 100°—110°	14·0	13·0	13·5	11·0
Above 110°	8·0	8·5	8·5	4·0

An inspection of these figures will at once show the extreme difference between the two methods. If the sample be judged upon the trade test it is an uncommonly good one, while in reality it should be condemned. The present method is suggested as one that is simple to work, does not require very delicate apparatus, and gives results comparable with practical experience. It is, of course, necessary that both buyer and seller should use the same test, and that the conditions of experiment should be carefully defined. It should not be difficult to do this if the question were treated in the same manner as the analysis of tanning materials by the International Association of Leather Trades Chemists. The persistent retention of a method which is admittedly unscientific and has been proved to be inaccurate cannot be too strongly condemned.

Discussion.

Mr. J. T. Wood was of opinion that an ideal spirit for degreasing should have a constant boiling point of about 90° C. Such a spirit might be found in benzol if the price admitted of its use. Spirit distilling above 110° C. was very undesirable, as it was difficult to remove it from the grease, so that it was not only lost, but also diminished the value of the grease. He quite agreed that the analysis of benzine ought to be put upon a proper basis, and some uniform and scientific method of distillation accepted. He suggested that the I.A.L.T.C. might do something in the matter.

Mr. F. D. Toyne wrote that analysis of spirit should always be directed to the estimation of the first runnings, say up to 80° C., and the last above 110° C. The most valuable fractions were those which had the highest boiling point consistent with their ready expulsion from the residual grease. He trusted Mr. Trotman's paper would have the effect of bringing about a change in the test upon which sellers of benzine approached the market.

Mr. F. V. Barnes said that coal-tar benzines were sold upon a simple distillation test, but when he really wanted to obtain any information about them, he invariably substituted some form of dephlegmator.

Mr. G. A. Shankland said that experience had shown him that the low boiling fractions were always expensive, and thought it of supreme importance that these solvents should be sold upon the results of a test which really gave some information upon that point. He would like to know whether the author thought the last runnings as expensive as the first.

Mr. T. A. Gerard spoke of the decreased value of recovered grease to soapmakers caused by the use of an unsuitable spirit.

Mr. J. Dunford drew attention to the fact that spirits were often offered which showed, according to the trade test, exactly the same range of boiling points, but which had very different specific gravities. Would these show different results if properly fractionated?

Mr. S. R. Trotman in reply thought, that while on the whole the low fractions were the most expensive, it was often forgotten, firstly, that the fractions boiling above 110° C. were liable to lag behind and not do much work, and, secondly, that they finally required the expenditure of a considerable quantity of steam to completely expel them, the cost of which should be reckoned in addition to their deleterious effect upon the grease. He had no doubt that the spirits mentioned by Mr. Dunford would prove to be dissimilar if properly distilled. The chief characteristic of the "accepted" test was, that it totally failed to distinguish between spirits of dissimilar composition unless the dissimilarity was very great. He had rarely met with a benzine which would not pass the test.

Yorkshire Section.

Meeting held at Leeds, on December 3, 1906.

MR. F. W. BRANSON IN THE CHAIR.

THE PRESENT DEVELOPMENT OF THE ANALYSIS OF TANNING MATERIALS.

BY PROF. H. R. PROCTER AND MR. H. G. BENNETT, B.Sc.

(Contribution from the Leather Industries Laboratories of the University of Leeds.)

That there is a pressing need of some advancement in our methods of analysis of tanning materials will scarcely be questioned by anyone. The dissatisfaction which is felt with regard to the present official method of the I.A.L.T.C.,* involving the percolation of the tannin solution through unchromed powder in the filter bell, is almost universal, both with regard to the accuracy and concordance of its results, and the length of time necessary to obtain them. In the earlier processes for tannin analysis, stronger solutions were used (1 per cent. of total solids) than at present, and it was thought necessary to macerate a tannin solution for many hours with repeated portions of hide-powder, in order to ensure complete detannisation. At the same time, the hide-powders available were often imperfect, and contained always a certain amount of soluble and putrescible matters. The filter bell was therefore invented to get over these difficulties. The comparatively rapid detannisation effected by percolation through the bell effectually prevented any dangers due to putrefaction, and the method of rejecting the first portions of the filtrate overcame to a considerable extent the difficulties due to the presence of soluble matter. It is now, however, well known that with tannin infusions of the strength used at present (about 0·4 per cent. tannin) the detannisation can be completely effected by about 15 minutes' agitation with no more

*(International Association of Leather Trades Chemists.

hide-powder than is used in the filter bell, and such treatment is the basis of the indirect gravimetric method used by the American Leather Chemists' Association, and known as the "shake" method. The adoption of such a method as this by the American Leather Chemists, and its subsequent improvement in their hands, has brought into a strong light the defects of the filter bell method, the chief of which may be mentioned here.

In the first place, the method of rejecting the first 30 c.c. of filtrate to get rid of soluble matter is far from being a complete elimination of this difficulty, and much of our trouble may be traced to this imperfect removal of these "solubles" in the powder. Moreover, it has been shown that the composition of the filtrate is not only variable with regard to the "solubles" of the hide, but also with respect to the amount of soluble non-tanning matters, there being in fact a continuous change in the composition of successive portions of the filtrate, according to the degree to which the powder in the bell has been tanned by the solution in use, and according to the regularity of the flow of the infusion through all parts of the powder, this latter being always an uncertain factor. Again, the method assumes that any variability in composition of the filtrate due to dilution by the moisture contained in the air-dry powder used, is eliminated by the rejection of the first portions, whereas this conclusion is really open to considerable doubt.

Another objection to this method is found in the difficulties experienced in the satisfactory "packing" of the filter bell with the powder. This operation, as is well known, requires considerable care and some skill, differences in the manner of packing producing a distinct effect upon the results; and in the hands of different operators and with various powders this difficulty becomes very much more pronounced.

In the first place, we may note the impossibility of obtaining satisfactory powders, and more especially in getting them sufficiently absorptive, and at the same time sufficiently free from soluble matter. The complete detannisation of certain extracts by neutral powders is practically an impossibility, and these difficulties have been accentuated, rather than removed, by the unauthorised acidification of powders with lactic and other acids, which has caused swelling of the hide-powder in the bell, and an increase in the soluble matters of the powder. These same troubles are also manifest to an even greater extent in any attempt to analyse acid liquors by the filter bell arrangement. The powder swells so much as in many cases to render the filtration practically impossible, and even if successful, the amount of powder dissolved is enough to seriously vitiate the result.

One of the greatest objections to the filter bell is that large quantities of soluble non-tanning matters are removed by the powder when used in this manner. The solution is almost completely detannised by the first portions of the hide-powder it meets, and hence the detannised solution has to flow through a certain amount of fresh and very absorptive hide-powder, which will readily take out of solution many soluble non-tanning matters which are of an acid nature, or from some other cause are capable of absorption. Many derivatives of the tannins, such, for example, as gallic acid, are thus reckoned as tannins. This objection applied also to the earlier maceration method of treating the solution with several successive portions of fresh powder; and when the filter method was first introduced, the danger of removing such non-tannins by these methods of successive treatment with hide-powder, was not so fully appreciated as it now is. Most of these strong objections are inseparably associated with the method, and they are therefore only very partially overcome by the use of Dr. J. Paessler's "lightly chromed" powder, and, as far as the absorption of non-tanning matters is concerned, Dr. Paessler's powder is distinctly worse than the unchromed powders, though it is decidedly better in concordance of results.

The superiority of the American method in this respect over all methods involving the use of the filter bell, has been repeatedly urged, and is proved quite conclusively by an extensive investigation recently made by Parker and Bennett (see this J., pages 1193–1200), in which it is demonstrated that in the American method the absorption of the non-tannins by the powder is very much reduced, and in many cases completely prevented. The American method has also other claims to scientific accuracy. It employs a definite quantity of powder, chromed with a fixed amount of chrome alum, which not only makes the powder sufficiently acid for the efficient absorption of tannin, but also renders it more insoluble; and all remaining soluble matters are removed by a thorough washing of the powder immediately before use, so that the residues observed on "blank" experiments may be reduced to quantities of the order of 1 mgrm. of dissolved matter on 50 c.c. of the non-tan filtrate. It has also been shown clearly that by chroming in this way, the quality of the hide-powder used has a much less influence on the result, and that suitable powders can be prepared with much greater ease. Moreover, as the method consists in bringing the powder into contact with every part of the liquid to be detannised, by rapid agitation for a given time, it is (especially with the improvements suggested below) more rapid, more uniform, and less troublesome than the filter method, while it demands no special manipulative skill.

At the recent Conference of the International Association of Leather Trade Chemists at Frankfort, at which the American Association was represented by its President, the defects of the official filter method were made so obvious that a Commission was appointed to consider the whole question, and if possible bring the European and American practice into harmony. There can be little doubt that the result will be the abandonment of the filter method for some modification of the shaking process, but as the form adopted by the American Association does not seem in all respects adapted to European requirements without modification, the authors desire to bring forward at this stage various criticisms and suggestions.

From the point of convenience, the principal objections to the American method are the long time (nearly 24 hours) required for chroming the powder, which should be freshly done for each set of analyses; and the somewhat tedious method of determining the water correction by drying a portion of the squeezed powder. A theoretical objection may also be raised that the percentage of chrome actually absorbed by the powder under the American conditions is extremely small, and scarcely seems enough to secure the sufficient insolubility of the powder under unfavourable conditions, while the large amount of unabsorbed chrome salt leaves scope for great variations in the amount of acid taken up, which as regards absorptive powers seems a more important factor than the chrome itself.

As regards rapidity of chroming, it may be noted that the American official method stipulates that the amount of water used in soaking and chroming the powder should be 25 times the weight of the powder used. This seems to be a quite unnecessarily large quantity, and a course of experiments with varying quantities of water leads us to suggest 10 times the weight of powder as an alternative. This quantity is found to be quite enough to render the mixture sufficiently liquid for the agitation required, and will make the powder wet enough to ensure a sufficient regularity in chroming. It is, moreover, much more convenient in practice, and if the time occupied in chroming is to be reduced, which is strongly desirable, it will be necessary to use a more concentrated chroming liquor. As it stands the method is a mere waste of distilled water.

In the next place, the A.L.C. use only 3 per cent. of chrome alum on the weight of the powder. One of the main reasons for chroming is to render the powder insoluble, and all practical experience and all recent work on the hide-powder question show that the greater the chroming the less is the error. It has also been shown by Kopecky and by various American chemists that heavily chromed powders have their absorbency for tannin very little affected by the degree of chroming, so that it would appear that the quantity used in the American official method was decidedly small. If all the chromium used in this method is absorbed by the powder, it will only contain 0·45 per cent. of chromic oxide; and this is by no means a true assumption, the percentage absorption of chromium varying with the quality of the powder used.

The authors have used a powder in which only 22 per cent. of the chromium was absorbed. Again, if we are to be safe-guarded against variations in the quality of the unchromed powder, a greater degree of chroming seems desirable, enough, in fact to render all powders that are at all useable, practically uniform when chromed. The authors desire to suggest that 0·75 to 1 per cent. of chromic oxide or its equivalent in chromium is not too much for this purpose.

An equally important point is the time required for the preparation of the powder. The official method is to "digest the powder with 25 times its weight of water till thoroughly soaked. Add 3 per cent. chrome alum in solution. Agitate by either shaking or stirring occasionally for several hours, and let stand overnight. Wash, &c." This practically means that it is necessary to commence the preparation of the powder 24 hours or more before it is required for use. It is imperative that this inconvenient time should be shortened. The authors find that this cannot be done satisfactorily by merely increasing the amount of chrome alum. Experiment shows that 15 per cent. of chrome alum will put into a powder in one hour no more chromium than 3 per cent. under the same conditions, and will probably give the powder far more acid than is necessary. The authors therefore suggest the use of a basic chroming solution, such as is already used at the Vienna Versuchsanstalt. In this way a rapid chroming may be effected, and there seems no objection to this except that the amount of washing required may be slightly increased. Any objection of this kind is quite overcome when we consider the saving in time by the rapid chroming of the powder. It is known, too, that fresh and well washed and ground chrome leather will detannise quite well.

The following table gives the results of experiments made in chroming powders under varying conditions. To make the figures comparable, the results are stated as percentages of chromic oxide (Cr_2O_3) in the dry powder, after it is chromed, washed, and ready for use, though this may not be strictly correct in all cases. In parallel experiments with chrome alum and chromic chloride, such a quantity of the latter was taken as would give the same quantity of chromium as in the former.

Chromium absorbed under varying conditions.

Chroming material.	Tie.	Amount of water.	Absorption of total chromium used.	Chromium oxide in powder.
Per cent.	hours.		per cent.	per cent.
3·0 Chrome alum ...	24	25 times weight of powder	22·0	0·10
1·65 Cryst. chromic chloride	,,		16·5	0·07
1·65 Cryst. chromic chloride (made basic)*	,,		31·0	0·14
3·0 Chrome alum ...	1		4·4	0·02
1·65 Cryst. chromic chloride	,,		10·3	0·05
1·65 Cryst. chromic chloride (made basic)*	,,		13·2	0·06
3·0 Chrome alum ...	1	10 times weight of powder	23·1	0·10
3·0 Chromic alum (made basic)†	,,		52·7	0·23
15·0 Chrome alum ...	1		4·0	0·09
15·0 Chrome alum (made basic)	,,		40·4	0·91
8·25 Cryst. chromic chloride	1		14·3	0·32
8·25 Cryst. chromic chloride (made basic)*	,,		40·9	0·93
3·0 Chrome alum ...	24		71·7	0·32
3·0 Chrome alum (if totally absorbed)	,,		100·0	0·45

* These solutions were made basic to such an extent as would correspond to the theoretical salt $Cr(OH)SO_4$ or $CrCl_2(OH)$.

† These solutions were made basic to the same extent as is used in the manufacture of the Vienna hide-powder, which is 50 per cent. greater than in the other cases.

In all these cases the chromium was estimated by drying and ashing the powder, and afterwards igniting strongly with a mixture of magnesium oxide and sodium carbonate, by which means the chromium is all converted to sodium chromate. By the addition of hydrochloric acid and potassium iodide, the chromate liberates an equivalent amount of iodine which is estimated in the usual way with starch and $N/10$ thiosulphate solution.

It will be noticed from the table given, that with only one hour's chroming under A.L.C.A. conditions, very little is absorbed, the resulting powder being practically unchromed; but that when the amount of water used is reduced to 10 times the weight of the powder, about the same degree of chroming is obtained as with the larger quantity of water and the longer time. Moreover, when the chroming solution is made basic, more than half the chromium used is absorbed, and if the longer time be used, the absorption is again increased considerably. By far the most satisfactory results are obtained, however, through the use of larger quantities of chromium. When quantities of chromium were taken equivalent to the amount used in making the Vienna hide-powder, and the solutions made basic, the resulting powders contained practically 1 per cent. chromic oxide even with only one hour's chroming, but the required washing was somewhat increased.

The amount of chromium is not the only point of importance in the manufacture of a suitable hide-powder, and in rendering the powder sufficiently absorptive for tannin and at the same time less absorptive of gallic and other acids it is in all probability the amount of acid which is the determining factor. The use of volatile organic acids, such as formic, acetic, and lactic acids, is open to various strong objections. They are all difficultly volatile, and have been shown to have a decided effect upon the residues, and in addition they are difficult to estimate with accuracy. This last point is especially important when we remember the desirability of fixing some limits to the acidity of the powder or of the estimating the extent to which the acids occur, in the non-tannin filtrates and residues, and also of the control of the washing process, if some method such as is suggested below should be adopted. Hence, the chromic salt of some mineral acid would appear to be the best, and we are practically limited to either a basic chrome alum solution or a basic chromium chloride solution, since these are the only soluble salts which are readily obtained of constant composition. The authors have made various experiments with each of these, and find that both are fairly satisfactory, but that on the whole, the chloride solution is preferable, especially on account of the easy and accurate estimation of chlorine for purposes of control. The chloride solution is also free from the complication due to the useless presence of potassium sulphate in the solution of chrome alum, and hence less washing will probably be required. Again, the chloride and its basic salts are more readily soluble in water and less liable to precipitation when diluted by the water used in the chroming of the powder; and it appears from the results in the above table, that a less basic chloride will chrome a powder to a greater extent than a more basic sulphate under similar conditions. A point not fully explained is that even if chromed powders are washed until the wash liquors show no reaction for sulphate or chloride, these ions always reappear in the non-tannin filtrates, possibly due to substitution by tannic acids, or in some cases to double decomposition of the basic chrome salt with alkaline tannates. Investigation has shown that some portions at least of these compounds are volatile, and are in all probability free hydrochloric and sulphuric acids, so that in considering the effect upon the nature and weight of the residues, we think that the balance is in favour of hydrochloric acid as being the more volatile and less drastic reagent. The chromic chloride used in this work has been Kahlbaum's "crystallised chromium sesquichloride," the estimation of chromium in which is in agreement with the formula $CrCl_3 6H_2O$. As to what is the most convenient and desirable quantity to adopt for an official process, we do not at present wish to be dogmatic. What is wanted, is to get into the powder sufficient chromium to render it insoluble and uniform, and sufficient acid to ensure its efficiency in absorptive

hide-powder than is used in the filter bell, and such treatment is the basis of the indirect gravimetric method used by the American Leather Chemists' Association, and known as the "shake" method. The adoption of such a method as this by the American Leather Chemists, and its subsequent improvement in their hands, has brought into a strong light the defects of the filter bell method, the chief of which may be mentioned here.

In the first place, the method of rejecting the first 30 c.c. of filtrate to get rid of soluble matter is far from being a complete elimination of this difficulty, and much of our trouble may be traced to this imperfect removal of these "solubles" in the powder. Moreover, it has been shown that the composition of the filtrate is not only variable with regard to the "solubles" of the hide, but also with respect to the amount of soluble non-tanning matters, there being in fact a continuous change in the composition of successive portions of the filtrate, according to the degree to which the powder in the bell has been tanned by the solution in use, and according to the regularity of the flow of the infusion through all parts of the powder, this latter being always an uncertain factor. Again, the method assumes that any variability in composition of the filtrate due to dilution by the moisture contained in the air-dry powder used, is eliminated by the rejection of the first portions, whereas this conclusion is really open to considerable doubt.

Another objection to this method is found in the difficulties experienced in the satisfactory "packing" of the filter bell with the powder. This operation, as is well known, requires considerable care and some skill, differences in the manner of packing producing a distinct effect upon the results; and in the hands of different operators and with various powders this difficulty becomes very much more pronounced.

In the first place, we may note the impossibility of obtaining satisfactory powders, and more especially in getting them sufficiently absorptive, and at the same time sufficiently free from soluble matter. The complete detannisation of certain extracts by neutral powders is practically an impossibility, and these difficulties have been accentuated, rather than removed, by the unauthorised acidification of powders with lactic and other acids, which has caused swelling of the hide-powder in the bell, and an increase in the soluble matters of the powder. These same troubles are also manifest to an even greater extent in any attempt to analyse acid liquors by the filter bell arrangement. The powder swells so much as in many cases to render the filtration practically impossible, and even if successful, the amount of powder dissolved is enough to seriously vitiate the result.

One of the greatest objections to the filter bell is that large quantities of soluble non-tanning matters are removed by the powder when used in this manner. The solution is almost completely detannised by the first portions of the hide-powder it meets, and hence the detannised solution has to flow through a certain amount of fresh and very absorptive hide-powder, which will readily take out of solution many soluble non-tanning matters which are of an acid nature, or from some other cause are capable of absorption. Many derivatives of the tannins, such, for example, as gallic acid, are thus reckoned as tannins. This objection applied also to the earlier maceration method of treating the solution with several successive portions of fresh powder; and when the filter method was first introduced, the danger of removing such non-tannins by these methods of successive treatment with hide-powder, was not so fully appreciated as it now is. Most of these strong objections are inseparably associated with the method, and they are therefore only very partially overcome by the use of Dr. J. Paessler's "lightly chromed" powder, and, as far as the absorption of non-tanning matters is concerned, Dr. Paessler's powder is distinctly worse than the unchromed powders, though it is decidedly better in concordance of results.

The superiority of the American method in this respect over all methods involving the use of the filter bell, has been repeatedly urged, and is proved quite conclusively by an extensive investigation recently made by Parker and Bennett (see this J., pages 1193–1200), in which it is demonstrated that in the American method the absorption of the non-tannins by the powder is very much reduced, and in many cases completely prevented. The American method has also other claims to scientific accuracy. It employs a definite quantity of powder, chromed with a fixed amount of chrome alum, which not only makes the powder sufficiently acid for the efficient absorption of tannin, but also renders it more insoluble; and all remaining soluble matters are removed by a thorough washing of the powder immediately before use, so that the residues observed on "blank" experiments may be reduced to quantities of the order of 1 mgrm. of dissolved matter on 50 c.c. of the non-tan filtrate. It has also been shown clearly that by chroming in this way, the quality of the hide-powder used has a much less influence on the result, and that suitable powders can be prepared with much greater ease. Moreover, as the method consists in bringing the powder into contact with every part of the liquid to be detannised, by rapid agitation for a given time, it is (especially with the improvements suggested below) more rapid, more uniform, and less troublesome than the filter method, while it demands no special manipulative skill.

At the recent Conference of the International Association of Leather Trade Chemists at Frankfort, at which the American Association was represented by its President, the defects of the official filter method were made so obvious that a Commission was appointed to consider the whole question, and if possible bring the European and American practice into harmony. There can be little doubt that the result will be the abandonment of the filter method for some modification of the shaking process, but as the form adopted by the American Association does not seem in all respects adapted to European requirements without modification, the authors desire to bring forward at this stage various criticisms and suggestions.

From the point of convenience, the principal objections to the American method are the long time (nearly 24 hours) required for chroming the powder, which should be freshly done for each set of analyses; and the somewhat tedious method of determining the water correction by drying a portion of the squeezed powder. A theoretical objection may also be raised that the percentage of chrome actually absorbed by the powder under the American conditions is extremely small, and scarcely seems enough to secure the sufficient insolubility of the powder under unfavourable conditions, while the large amount of unabsorbed chrome salt leaves scope for great variations in the amount of acid taken up, which as regards absorptive powers seems a more important factor than the chrome itself.

As regards rapidity of chroming, it may be noted that the American official method stipulates that the amount of water used in soaking and chroming the powder should be 25 times the weight of the powder used. This seems to be a quite unnecessarily large quantity, and a course of experiments with varying quantities of water leads us to suggest 10 times the weight of powder as an alternative. This quantity is found to be quite enough to render the mixture sufficiently liquid for the agitation required, and will make the powder wet enough to ensure a sufficient regularity in chroming. It is, moreover, much more convenient in practice, and if the time occupied in chroming is to be reduced, which is strongly desirable, it will be necessary to use a more concentrated chroming liquor. As it stands the method is a mere waste of distilled water.

In the next place, the A.L.C. use only 3 per cent. of chrome alum on the weight of the powder. One of the main reasons for chroming is to render the powder insoluble, and all practical experience and all recent work on the hide-powder question show that the greater the chroming the less is the error. It has also been shown by Kopecky and by various American chemists that heavily chromed powders have their absorbency for tannin very little affected by the degree of chroming, so that it would appear that the quantity used in the American official method was decidedly small. If all the chromium used in this method is absorbed by the powder, it will only contain 0·45 per cent. of chromic oxide; and this is by no means a true assumption, the percentage absorption of chromium varying with the quality of the powder used.

distinctly damp, for the ordinary desiccating agent. A few drops of chloroform were added as an antiseptic. Under these conditions, the moisture in the powder remains practically constant for several days, but after 48 hours detannisations of the same solution showed rather higher non-tannins. It is possible that even after keeping for some days, re-washing might make the powder quite satisfactory, but this would involve a fresh determination of moisture in a portion of it by drying and weighing as in the case of the A.L.C.A.

One of the features peculiar to the A.L.C. method is the agitation of the solution in detannising, by "shaking for 10 minutes in some form of mechanical shaker," the usual form being the ordinary "milk shake" machine. Mr. H. C. Reed, in an essay for the Klipstein Prize, states that a rotating arrangement of about 60 revolutions per minute used for 15 minutes will give practically the same results as 10 minutes in the milk shake, while the rotating machine is much simpler and more convenient. The authors can confirm this statement in general terms, but think that further experiments are desirable to determine whether a longer time is required in the case of certain tanning materials which detannise with difficulty. It is certain that a "churn" arrangement would be more generally acceptable than the shake machine, which is noisy and uses considerable power, while its advantages over a slow maceration method are equally evident.

The regulations of the A.L.C.A. state that "the non-tannin filtrates must not give a precipitate with a solution of 1 per cent. gelatin and 10 per cent. salt. The disadvantage of this testing solution is that it gelatinises at the temperature of the laboratory, and as a substitute a solution of gelatin peptones (practically a modified "collin") was made up as follows:—5 grms. of good gelatin was soaked in water and dissolved on the water-bath to 50 c.c.; 10 c.c. of $N/1$ sodium hydroxide were added and the mixture heated in the water-bath for 20 minutes; 10 c.c. of $N/1$ hydrochloric acid were then added, the liquid made up to 100 c.c., filtered, and two drops of chloroform added as a preservative. The mixture is at least as sensitive as the gelatin solution, and either will just show visible opalescence with a solution of gallotannic acid of 1 part in 100,000. Since, therefore, all detannised filtrates are tested in this way, any error caused by imperfect detannisation cannot exceed 0·0005 grm. per 50 c.c., and obviously any higher result in tannin obtained by other methods must depend either on lessened solubility of the powder, or absorption of substances which are not tannins. As the total solubility of the powder can be reduced by careful washing to less than 0·001 per 50 c.c., there is obviously not much room for the first of these explanations.

The authors propose continuing their work regarding the details of the process, and especially with regard to the filtration of opalescent tannin solutions, but in view of the deliberations of the Commission now sitting, have been anxious to publish the results of their investigation, so far as it has proceeded, without delay.

Discussion.

Mr. H. G. Bennett said a great many interesting points had arisen in connection with the constitution of chromium salts. A slightly different effect was obtained in the chroming of hide-powder by chrome alum dissolved in the cold, and by a similar solution previously boiled. They hoped to deal with the actual constitution of basic chromium salts at a future date. The fact that Prof. Procter advocated the abolition of a method of his own invention which had been in vogue for many years showed clearly how much he desired improvement in the methods of analysis The German Section of Leather Chemists had raised objections to any change, and their conservative attitude had been an obstacle to advancement.

Mr. J. A. Craven realised the importance of obtaining more accurate results, but thought it was a serious thing to change a method which had been in use so long and to which tanners had grown accustomed. Probably alterations would be felt more by people in the trade than the chemist could realise. More extracts than crude materials were sold on the percentage. Tanners had begun to realise the value of analyses, and now stipulated for a certain percentage of tannin. It would be difficult to convince them that they were getting the same value for their money if the new method gave lower results than the old one on the same materials.

Mr. T. Fairley asked if it was possible to devise a factor showing the relationship between the former method and this later one. Reports could then be given with percentages by each method.

Mr. W. McD. Mackey pointed out that if a factor were used it would go to prove that the old method was as good as this one, whereas what was aimed at was a nearer approach to accuracy. It was his custom to state the method used in each report. Merchants and tanners had built up their data on certain methods, and change would be awkward. Would it not be advantageous to have a standard temperature for the shaking in the American method?

Mr. W. B. Hill hoped that Prof. Procter would have said more about the absorption of acid. The maceration method required over an hour to get good results.

Prof. Procter, in reply, mentioned a paper given by Kopecky (Collegium, 1906, p. 97) in which he described a method of using the maceration process with highly chromed powder. The first results were good; but as the hide-powder was kept, worse and worse results were obtained, the difficulty arising from changes which took place in the powder, probably due to loss of moisture which lessened its absorbency. It was not improbable that the German lightly chromed powder would ultimately suffer in the same way. Mr. Kopecky in the States, and Mr. J. T. Wood of Nottingham, had used commercial chrome leather machine shavings damp, after washing, and had obtained good results. Heavy chroming did not interfere with absorption. The chemists working specially for the leather trade in England had agreed to give the results by both methods for a few months without extra charge, and in view of the approaching change it was desirable to determine contracts by more than one method. The Commission could not unfortunately report before April. No advantage was gained by a factor connecting the two methods if one of them gave wrong results.

THE JUBILEE OF THE COAL TAR COLOUR INDUSTRY.

AMERICAN CELEBRATIONS.

New York.

On Saturday, October 6, a banquet was given to Sir Wm. H. Perkin at Delmonico's. Dr. Chas. F. Chandler occupied the chair, and some 400 guests were present. Mention was made of the general fund that was being solicited for a Perkin Chemical Library, to be installed at the Chemists' Club. After the usual loyal toasts, and a welcome from the City of New York by the Hon. Patrick F. McGowan, Dr. Hugo Schweitzer, Secretary of the Organising Committee, gave an address, in which he described eloquently the history of the discovery o

mauve, the evolution of the coal tar colour industry, the synthesis of medicinal remedies, and the new fields now opened, in all of which coal tar forms the base.

Dr. Wm. H. Nichols then handed to Sir Wm. H. Perkin the first impression of the Perkin medal, in gold, which is to be given annually to the American chemist who has most distinguished himself by his services to applied chemistry. Mr. Adolf Kuttroff, treasurer of the Organising Committee, next presented a tea service as a token of gratitude from American friends.

Dr. W. F. Hillebrand, president of the American Chemical Society, presented the honorary membership of the American Chemical Society. The other speakers were President N. Murray Butler, Prof. Hermann Schumacher (Bonn), President Ira Remsen, Prof. Nernst (Berlin), Dr. H. W. Wiley, and Mr. H. A. Metz.

Sir Wm. H. Perkin, in reply, expressed himself as both honoured and gratified by the warm welcome extended towards him, and for the presentation made. He trusted that the medal would encourage and stimulate chemists to increased activity in research, and he felt sure that the tea service would be valued not only by himself, but by Lady Perkin and his family. He also greatly appreciated the association of his name with the American Chemical Society. After thanking the various speakers for their kind references, Sir Wm. Perkin gave the history of his life's work from the discovery of mauve to the establishment of the coal-tar colour industry. He then referred to the subsequent developments which enabled him to retire from business and once more occupy himself with pure scientific research. In conclusion, he alluded to the influence which the industry had had upon the development of science, and the vast amount of employment it had given to the working classes.

Boston.

On Wednesday, October 10, Sir Wm. H. Perkin was entertained at the Algonquin Club at Boston. About 170 representatives of chemical industry were present. The chair was taken by Mr. F. E. Atteaux, and Prof. H. P. Talbot of the Mass. Inst. of Technology acted as toastmaster. After the usual loyal toasts, Governor Curtis Guild, Jr., welcomed Sir William on behalf of the Commonwealth of Massachusetts, the first textile State in the Union; and the Hon. Thos. A. Mullen followed on behalf of the City of Boston. After speeches by Senator Cabot Lodge; Capt. W. Wyndham, British Consul at Boston; President Henry S. Pritchett, Mass. Inst. of Technology; and Mr. Wm. Whitman, President of the Arlington Mills, Dr. W. H. Walker presented Sir Wm. Perkin with a silver punch bowl, for which Sir William expressed his thanks.

On Thursday morning Sir William and his party visited Harvard University, where they were received by President and Mrs. Eliot, and in the afternoon the Mass. Institute of Technology.

Obituary.

Edmund H. Miller, M.A., Ph.D.

Edmund H. Miller was born at Fairfield, Connecticut, U.S.A., on September 12, 1869. He was admitted to Harvard University in 1886, and in 1887 he entered the School of Mines of Columbia University for special preparation in the branches of analytical and applied chemistry. He graduated as Ph.B. in 1891. From 1891 to 1894 he held the post of Assistant in Assaying, and from 1894 to 1897 that of Tutor in Analytical Chemistry and Assaying. In 1897 he was appointed Instructor in Columbia University, Adjunct Professor in 1901, and Professor of Analytical Chemistry and Assaying in 1904. In conjunction with his students, Dr. Miller published some forty papers on subjects in inorganic and analytical chemistry, including papers on Ferro-, Chromic-, and Cobalticyanides, and on the Platinum metals and their alloys. He published the following books: "Notes on Assaying," in conjunction with Dr. Ricketts; "Calculations in Analytical Chemistry," and, "Quantitative Analysis for Mining Engineers." In addition to his duties in the Department of Chemistry, Dr. Miller was engaged with the administrative affairs of the Columbia University, serving on the Committee of Admissions for three years, during two of which he was Chairman. As a technologist, he had had some practical experience in the laboratories of Messrs. Ricketts and Banks in 1891, and as Chemist for the Arlington Manufacturing Company. Dr. Miller was a member of the Society of Chemical Industry, and of the Committee of its New York Section; a member of the American Chemical Society, Vice-Chairman of its New York Section in 1902–3, Chairman in 1904, and later he was made a Vice-President of the Society. His death took place on November the 8th.

William H. Chandler, Ph.D.

William H. Chandler was born at New Bedford, Mass., on December 13, 1841, and graduated at Union College, Schenectady, in 1862. In 1872 he received the degree of Ph.D. from Hamilton College. Having taught for four years in the Columbia School of Mines, in 1871, he received an appointment in Lehigh University, as Professor of Chemistry. He finally became President of the University, acting also as Emeritus Professor of Chemistry. Dr. Chandler, in 1898, published an encyclopædia of universal knowledge. He was a member of this Society, and also of the American Chemical Society, a Fellow of the Chemical Society of London, member of the Société Chimique de Paris, and of the American Association for the Advancement of Science. He died on November the 30th.

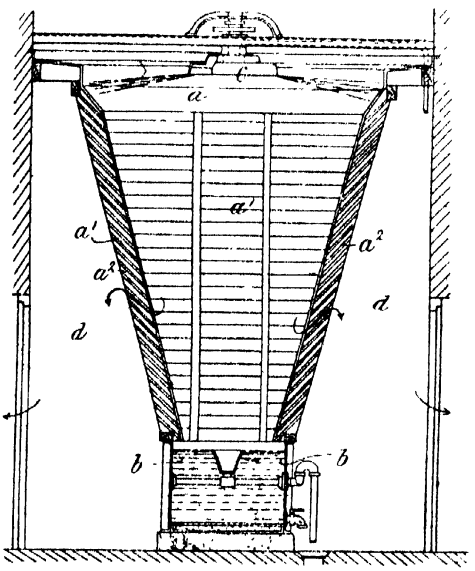
ENGLISH PATENTS.



Drying of granular, pulverulent, and other substances ——. A. J. Lehmann, Liverpool. Eng. Pat. 23,106, Nov. 10, 1905.

THE materials to be dried are supported on trays, or by other suitable means in a chamber into which a current of air is forced, under pressure, through several inlets, so that it passes through the chamber and over the materials with a whirling motion in a similar manner to that described in Eng. Pats. 11,705 of 1904 and 3645 of 1905. The moisture-laden air is withdrawn at a slightly higher rate than the fresh air enters to ensure a slight vacuum in the chamber. When dry the contents of the trays are tipped on to the inclined bottom of the chamber from which they are removed.—W. H. C.

Cooling and drying fluids; Processes for ——. F. Kneller, Kalk, and W. Schumacher, Berlin, Germany. Eng. Pat. 24,927, Dec. 1, 1905.

THE fluid is cooled by causing it to exchange heat with a single cooling medium only, which circulates through successive cooling coils. The cooling medium is caused to evaporate at different pressures and consequently at different temperatures in successive coils.—W. H. C.

Purifying, humidifying, or cooling of air or other gaseous fluids. T. F. Shillington and J. A. Hanna, Belfast. Eng. Pat. 1003, Jan. 13, 1906.

THE claim refers to the spraying device described in Eng. Pat. 10,552 of 1905 (this J., 1906, 419). The air or other gas enters the top of the inverted conical chamber, *a*, and after becoming mixed with the spray from the nozzles, *c*, passes in the direction indicated by the arrows, through the spaces, a^2, between the louvres, a^1, which form the sides of the chambers, into the distributing flue, *d*. The excess of liquid is stopped by the louvres, a^1, trickles down, and collects in the reservoir, *b*, carrying with it any impurities taken up from the air.—W. H. C.

FRENCH PATENT.

Mixture of gases or vapours with liquids; Process for the production of a ——. G. Meyersberg. Fr. Pat. 368,235, July 20, 1906.

SHORT pistons or columns of liquid and gas are caused to succeed one another very rapidly so that they become intimately mixed. The liquid is delivered from a distributing wheel or turbine, the rim of which is divided by partitions into a number of compartments. The width of the partitions increases from the inlet to the delivery side of the wheel, which is rotated in front of a similarly divided wheel, so that the width of the partitions governs the length of each fluid piston. As each liquid piston passes from one wheel to the other, it draws in a short piston of gas from the space between, and the mixture is delivered on the further side.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 1140.)

Hydrocarbons; Explosive combustion of ——. *II.* W. A. Bone, J. Drugman, and G. W. Andrew. Chem. Soc. Trans., 1906, **89**, 1614–1625. (See this J., 1906, 526.)

MIXTURES of ethane and oxygen, and ethylene and oxygen, corresponding to $C_2H_6+O_2$ and $3C_2H_4+2O_2$, respectively, were ignited in vessels having different surface areas per unit volume, with the view of discriminating between the various combustion products, it being argued that the greater the cooling effect of the walls of the containing vessel, the larger will be the proportion of primary products of combustion. The results obtained were entirely in accord with the view previously put forward (*loc. cit.*) that combustion both above and below the ignition point involves the initial formation of hydroxylated molecules.

Experiments were also made on the explosion of an equimolecular mixture of ethane and oxygen, and a mixture of butane and oxygen corresponding to $C_4H_{10}+2O_2$, in a stout leaden coil immersed in a water-bath, which, after the explosion, could be rapidly emptied, and then immediately filled with cold water. Examination of the products showed that in all cases a considerable proportion of methane (6·2—8·1 per cent.) was present, and that from 15 to 22 per cent. of the original oxygen appeared in the condensed products of combustion. As a whole, and taking into consideration the higher temperature, it appears almost certain that in exploding, as in ordinary inflammation, hydroxylated molecules are initially produced; and there is no evidence of a preferential combustion of carbon.—A. S.

Coal production and consumption in the principal countries of the world. Bd. of Trade J., Nov. 29, 1906. [T.R.]

THE following particulars, relating to the production and consumption of coal in the principal countries of the world, are extracted from a Return [321/1906] recently issued by the Board of Trade:—

Production.—The production of coal in the five principal coal producing countries of the world in 1903, 1904, and 1905 was as follows, in long tons:—

Countries.	1903.	1904.	1905.
	Tons.	Tons.	Tons.
United Kingdom	230,334,000	232,428,000	236,129,000
Germany.....	114,763,000	118,874,000	119,849,000*
France.....	33,668,000	32,964,000	34,778,000*
Belgium	23,415,000	22,395,000	21,506,000
United States of America	319,068,000	314,563,000	350,821,000*

* Provisional figures.

The production of coal in 1905, in the United Kingdom, Germany, France, and the United States was greater than in any previous year, but in Belgium the output again shows a decline. The total known coal production of the world (exclusive of brown coal or lignite) in 1905 was about 840 million tons. The following statement shows the production of coal in the principal British Colonies and possessions in the years 1903, 1904, and 1905, in long tons:—

Countries.	1903.	1904.	1905.
	Tons.	Tons.	Tons.
British India	7,438,000	8,217,000	8,425,000
Australian Commonwealth	7,112,000	6,854,000	7,496,000
New Zealand	1,420,000	1,538,000	1,586,000
Canada	6,825,000	6,705,000	7,836,000
Transvaal	2,012,000	2,151,000	2,327,000
Cape of Good Hope .	185,000	154,000	147,000
Natal	714,000	858,000	1,129,000

Nearly the whole of the output of the Australian Commonwealth is produced in New South Wales. The principal lignite-producing countries are Germany, Austria, and Hungary, which in 1904 produced 47,853,000 tons, 21,635,000 tons, and 5,430,000 tons respectively, whilst the provisional figures available for the production of Germany in 1905, indicate an increased production of 51,655,000 tons. In Austria the output of lignite for 1905 was 22,327,000 tons. The quantity of lignite produced in the United States is included in the figures for the production of coal already given. The latest available figures giving the production of lignite separately, relate to 1904, when it amounted to 5,725,000 tons.

Consumption.—The consumption of coal in some of the chief consuming countries is shown in the following statement:—

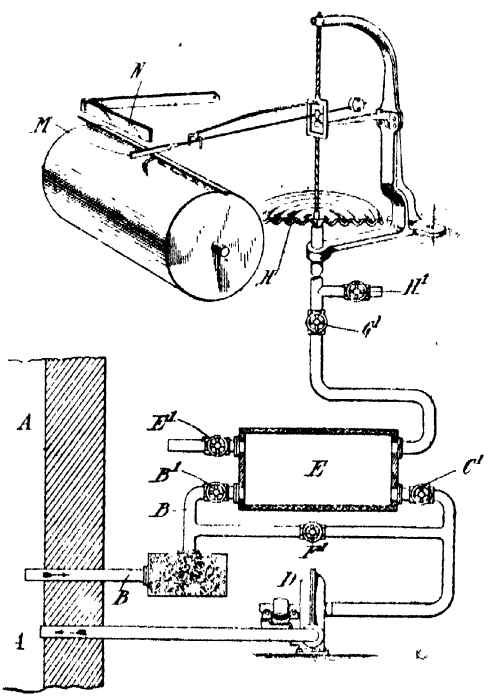
Countries.	1903.	1904.	1905.
	Tons.	Tons.	Tons.
United States	314,114,000	307,610,000	343,280,000*
United Kingdom	166,532,000	166,609,000	169,017,000
Germany	100,164,000	104,094,000	106,715,000*
France	40,571,000	45,433,000	46,046,000*
Russia	20,882,000*	22,724,000*	20,890,000*
Belgium	20,682,000	19,726,000	19,661,000
Austria-Hungary	17,987,000	18,421,000	19,390,000*

* Provisional figures.

ENGLISH PATENTS.

Fuel; Artificial ——, and manufacture thereof. Internat. Patent Fuel Syndicate, Ltd., and J. J. Shedlock, London. Eng. Pat. 22,677, Nov. 6, 1905.

SMALL or refuse coal, mixed according to its character with a suitable quantity of liquid hydrocarbons, such as gas tar, astatki, refuse petroleum, &c., is fed into a hopper and conveyed to an automatic mixer. The mixture is passed through an automatic measuring and feeding device into a cylindrical gas-tight chamber. The chamber contains a number of hollow circular shelves or trays, and the mixture is moved along each shelf, by radial arms on a central vertical spindle, until it drops through an aperture to the shelf below. Steam, hot air, or furnace gases are drawn through the hollow shelves by a fan, and the fuel mixture is heated so as to produce a tacky pitch-like coating. The heated mixture is discharged at the bottom of the chamber through an automatic device which does not allow the escape of gas, and is formed into briquettes in a press. The gases and vapours evolved in the heating chamber are withdrawn by an exhauster, and passed through a condenser.—A. T. L.



Coal-washing installations; Fine-coal or schlamm extractor for ——. G. Smith and the Hardy Patent Pick Co., Ltd., Sheffield. Eng. Pat. 25,135, Dec. 4, 1905.

THE water from the coal washers, having the fine coal in suspension, is led through a long settling tank, of suitable length and depth, from the discharge end of which the top- or clean water overflows into a receiver, whence it is pumped back into the washers. An endless chain, provided with scrapers, travels slowly along the bed of the tank and up an inclined shoot, carrying with it the sediment of coal, allowing the water to drain back on the shoot, and delivering the coal-mud where desired. Preferably, the sides of the settling tank converge towards the bottom, and the scrapers are shaped so that they will always fit themselves to the sides and bottom and thus compensate for wear.—H. B.

Washing coal, coke, minerals, and the like; Machine for ——. G. H. Rayner and The Hardy Patent Pick Co., Ltd., Sheffield. Eng. Pat. 1660, Jan. 22, 1906.

IN the type of apparatus in which the material to be treated is conducted up an inclined trough against a current of water, which carries the small coal, &c., to the lower end, whilst the dirt settles between the scrapers of the conveyor, and is collected at the upper end, means are provided for raising, or raising and rotating, some of the scrapers at certain parts of the trough, so that the material is carried back and re-washed; efficient re-washing is ensured by admitting air or water under pressure through perforations in the trough of the conveyor. In the arrangement described, the material is released for re-washing by every second scraper at one point, and by the other scrapers at another point, both points being near the upper end of the trough.—A. T. L.

[*Flue*] *Gases; Method and apparatus for estimating and recording the quality of ——.* Cambridge Scientific Instrument Co., Ltd., and C. V. Burton, Cambridge. Eng. Pat. 22,919, Nov. 8, 1905.

The valves, E^1, F^1, and G^1, being closed and the valves B^1, C^1, open, flue gas is continuously circulated by the pumping apparatus, D, from the chimney, A, by way of the supply pipe, B, through the diffusion chamber, E, and back by the return pipes, C, to the chimney. Thus a sample of flue gas is secured in the chamber, E. At the same time the valve, H^1, remains open so that the

pressure inside the chamber, H, is the same as the surrounding atmospheric pressure. After the lapse of a short interval of time (say, one minute), the valves, B^1, C^1, are closed, while the valve, E^1, after being momentarily opened to equalise the pressure inside and outside the chamber, E, is closed again, while at the same time the valve, H^1, is closed and the valves, F^1, and G^1, are opened. Flue gas can now circulate from the supply pipe, B, to the return pipe, C, through the by-pass, F, while the chambers, E, and H, are shut off from communication with anything but one another, and are initially at atmospheric pressure. The flue gas in the chamber, E (composed of porous material or containing a porous septum) being of greater density than the air outside diffuses outwards through the porous septum more slowly than the air diffuses in. This causes the pressure in the chambers, E, H, to rise above the atmospheric pressure and to continue rising until a maximum is reached after which it again begins to diminish. The maximum pressure is greater the greater the density of the flue gas and where the fuel being burnt is coal or coke the density of the flue gas is generally determined by the proportion of carbon dioxide present. Thus by registering the variations of pressure within the chambers, E, H, a record is obtained showing from time to time the density of the flue gas, and, approximately, its carbon dioxide content. After momentarily opening E^1 to the air, the valves, G^1 and F^1, are opened, thus connecting the box, E, with a manometer box, H, to which is attached an indicator, M. A hammer, N, actuated by clockwork, strikes the indicator, M, at regular intervals, thus recording the pressure in the box, E, after the gas has diffused for a given time. More gas is then automatically admitted by a turn of the spindle operating the three valves mentioned above, the pressure inside and outside the box again equalised by opening E^1, and diffusion allowed to take place as before. B. J. S.

Fire-clay and other retorts for making gas and for other purposes. G. H. Timmis, Stourbridge, and W. D. Jones, Bristol. Eng. Pat. 23,464, Nov. 15, 1905.

Two or more horizontal fire-clay retorts are made in one piece, the one above the other, and are united for the whole of their length, or are provided with holes or passages through the connecting wall, for the passage of the hot gases between them. The retorts are fitted with a single cast-iron mouthpiece, gas-outlet, and ascension-pipe in common. A movable tray, adapted to be fitted upon lugs on the sides of the mouthpiece, is provided to facilitate the charging and drawing of the upper retorts —H. B.

Filaments of electric glow lamps; Process of electrically connecting the —— with their supply wires. H. Kuzel, Baden, Austria. Eng. Pat. 12,153, May 24, 1906. Under Int. Conv., Aug. 4, 1905.

SEE Fr. Pat. 366,267 of 1906; this J., 1906, 1035.—T. F. B.

FRENCH PATENTS.

Coke-oven; Recovery —— working with or without regeneration of heat without reversal of the gaseous currents within the oven. E. Clère. Fr. Pat. 368,217, July 19, 1906.

THE gaseous fuel mixed with air is burnt in a combustion chamber situated beneath the ovens, and the gases are only admitted to the heating flues after the combustion has been completed. When it is desired to utilise the heat of the waste gases, the reversal of the currents is effected in a subsidiary chamber, the direction in the oven flues remaining always the same.—W. H. C.

Hydrocarbon liquid; Manufacture of a ——. E Luserna di Rora. Fr. Pat. 368,403, Feb. 19, 1906.

ACETYLENE and water-gas are passed simultaneously through a vessel heated to about 200° C., and the gaseous mixture is then led through a refrigerating apparatus, within which it is said to deposit a highly refractive liquid (named "Azurrol"), of sp. gr. 0·6—0·8, which, it is stated, "may advantageously replace sulphuretted hydrogen, petroleum spirit, and other similar liquids."—H. B.

Alcohol for lighting, heating, and power purposes; Treatment of ——. G. E. Lebœuf. Fr. Pat. 367,985, July 11, 1906.

THIS treatment of alcohol, carried out with a view of producing a carburetted and illuminating mixture useful for lighting, heating, or motive purposes, consists in partially transforming the alcohol into more highly illuminating bodies, such as ethers, acetone, or benzoïn, and in adding, as required, an animal, vegetable, or mineral hydrocarbon. The process is applicable to alcohols of all kinds and all concentrations, and to the ethers and other compounds derived from them.—T. H. P.

Coal gas and the like; Process of cooling and condensing —— so as to avoid decomposition of the heavy hydrocarbons and similar substances. P. A. Mallet. Fr. Pat. 361,778, Sept. 19, 1905.

A JET of atomised liquid, such as water, is injected into the ascension pipes or the like, so as to reduce suddenly the temperature of the gas to, say, 100° C., whereby the condensed tar is kept in a fluid state, and produces no stoppages.—H. B.

Suction gas producer. A. Béchevot. Fr. Pat. 361,792, Dec. 8, 1905.

THE hopper of the producer is provided at its lower part with a conical extension, which projects into the combustion chamber and is provided with an external flange at a level below that of the gas outlet pipe of the producer. The area of the annular space between the flange and the wall of the producer is equal to that of the gas outlet pipe; by this means the formation of channels in the fuel, through which the gas may take a short cut to the outlet, is prevented. The fuel in the producer rests on a conical, hollow, steel bed, which serves as a vaporiser, through which the air supply is drawn on its way to the bottom of the fuel; this device is kept filled to a constant level with water overflowing from the main vaporiser, which latter is situated at the side of the producer and is heated by the hot gases. The air-inlet to the producer is controlled by a flap-valve, which can be set, by means of an adjustable stop, to any desired limit of movement.—H. B.

Gas; Process and apparatus for making ——. P. I. Cohen. Fr. Pat. 368,508, July 30, 1906.

SEE U.S. Pat. 827,081 of 1906; this J., 1906, 842.—T. F. B.

Gas works; Process for increasing the yield of gas, with simultaneous automatic revivification of the purifying materials (oxide of iron) in ——. E. E. P. M. Blanc and P. A. Caton. Fr. Pat. 368,520, July 30, 1906.

A CERTAIN proportion of air is mixed with the coal gas, the air having previously been brought into contact with tar heated to a temperature short of 200° C., whereby the air becomes impregnated with lighting hydrocarbons contained in the tar. The mixture of gas and air is enriched further with benzol, and is then passed through purifiers containing oxide of iron. Owing to the presence of oxygen in the gas, the revivification of the oxide proceeds continuously and simultaneously with the removal of the sulphur from the gas.—H. B.

Pyrophoric alloys for igniting and lighting purposes. C. Auer von Welsbach. First Addition, dated July 18, 1906, to Fr. Pat. 337,320, Oct. 31, 1903 (this J., 1904, 484).

IN preparing the pyrophoric alloys of iron and an earth metal, such as thorium, as described in the principal patent, a small proportion of cerium is added. This may be effected by using the commercial salts of thorium, &c., which contain cerium as an impurity.—H. B.

Glow-bodies, especially filaments of tungsten; Manufacture of metallic —— for electric lamps. Deutsche Gasglühlicht A.-G. (Auerges.). Fr. Pat. 367,386, June 8, 1906.

A CONTINUOUS, instead of an alternating, current is employed in the process of concretion of tungsten filaments, wherein the crude filament is heated to incandescence in a neutral atmosphere.—H. B.

Glow-bodies for incandescence electric lamps; Manufacture of metallic ——. Deutsche Gasglühlicht A.-G. (Auerges.). Fr. Pat. 368,225, July 19, 1906.

FILAMENTS composed of powdered metallic molybdenum, tungsten, vanadium, or tantalum, and a carbonaceous agglutinant, are heated in an atmosphere of ammonia gas, or of a mixture of hydrogen and nitrogen, whereby the carbon is eliminated from the filaments in the form of cyanogen and hydrocyanic acid, and the risks attendant upon the use of an oxidising gas are avoided.—H. B.

Filaments of vanadium carbide. Cie. Franç. pour l'Exploitation des Procédés Thomson-Houston. Fr. Pat. 368,506, July 30, 1906.

SEE Eng. Pat. 19,264 of 1905; this J., 1906, 803.—T. F. B.

GERMAN PATENTS.

Lignite briquettes; Process and apparatus for scrubbing the fumes ("Wrasen") evolved in the manufacture of ——. H. Emonds. Ger. Pats. 166,355, March 26, 1904, and 166,356, Jan. 1, 1905.

THE fumes are passed by means of forced draught, or by a fan or the like, up a washing tower divided by horizontal partitions into a number of compartments, each provided with a rose through which water is forced under pressure. The carbonaceous particles in the fumes and the particles of water move in opposite directions, in nearly straight, vertical lines, and on meeting, the former are brought to a standstill and saturated with water, whereupon they fall with the descending water. According to Ger. Pat. 166,356, the washing tower is divided into compartments by inclined, helical, or horizontal partitions of wire gauze or of perforated sheet metal, and the carbonaceous particles are separated as a mud by impact with water, steam, or other fluid substance. The tower, also, may be provided with a head-piece with the walls tapering downwards, and resting in the upper part of the tower. The upper parts of the walls of the head-piece taper upwards, and inside are baffle-plates, whereby a whirling motion is imparted to the fumes, and the separation of the carbonaceous particles is improved.—A. S.

Briquettes from lignite and lime; Process for the manufacture of weather-resistant ——. F. Richter. Ger. Pat. 165,804, Aug. 12, 1904, and Ger. Pat. 166,836, Dec. 9, 1904, Addition to Pat. 165,804.

To the powdered lignite is added as much quicklime as will correspond to the sulphuric acid present in the lignite, and the mixture is formed into briquettes in the usual manner. It is stated that calcium sulphate is formed, if a sufficiently high pressure be employed, and acts as binding agent. According to Ger. Pat. 166,836, the mixture of lignite and lime is warmed before being compressed into briquettes.—A. S.

Water-gas or mixed gas; Process for the continuous production of ——. G. Horn. Ger. Pat. 167,112, May 2, 1903.

THE apparatus comprises a vertical retort, the height of which is varied according to the kind of combustible used, and a decomposing chamber below the retort, and forming a direct continuation of the same. One or more sides of the decomposing chamber are formed of gratings through which highly superheated steam is introduced. The combustible in the form of fine powder or spray is allowed to fall freely through the vertical retort, which is heated to incandescence. The incandescent, carbonaceous material reacts with the steam in the decomposing chamber, with the production of water-gas, whilst non-volatile impurities are deposited below the decomposition-zone.—A.

Air-gas [Carburetted air] of uniform composition; Process and apparatus for the manufacture of ——. G. Spork. Ger. Pat. 169,179, Jan. 17, 1904.

THE cylinder in which the carburetted air is produced has a valve near the exit end for the introduction of the carburetting liquid, and a second valve nearer the other end of the cylinder for the introduction of air. When the piston working in the cylinder is set in motion, the air is partially exhausted from the cylinder, and a definite quantity of the carburetting liquid is drawn in. This rapidly evaporates, and mixes with the air drawn in after the piston passes the air-inlet valve, whilst, on the return stroke of the piston, the mixture is compressed and forced out from the cylinder into a gas-holder.—A. S.

Heating gases; Device for the production of ——. P. Mongenast. Ger. Pat. 169,751, March 4, 1904.

THE gases produced in a combustion-shaft, before they come in contact with any cold surfaces, are led through a mixing chamber, in the walls of which are air-inlet openings. In the mixing chamber is a series of horizontal partitions forming parallel passages for the gases. Air-supply pipes pass vertically through perforations in the horizontal partitions.—A. S.

Gases evolved during the charging of vertical gas-retorts; Device for leading away the ——. Dessauer Vertikal-Ofen Ges. m.b.H. Ger. Pat. 167,277, Oct. 1, 1904.

PROTECTING walls or plates are fixed on the sides of the charging hoppers, and abut against the charging floor above the retorts, in order to prevent the evolved gases having exit sideways. Also, above the charging floor is a flue, acting as a chimney, between the coal wagons, whereby the tendency of the gases to rise is favoured.—A. S.

ERRATUM.

(*Continued from page* 1142.)

UNITED STATES PATENT.

Furnace; Retort [for wood distillation]. P. Brown, Bellingham, Wash. Assignor to Troy Chem. Manufacturing Co., Ltd., Troy, Idaho. U.S. Pat. 835,237, Nov. 6, 1906.

THE apparatus, which is adapted for the distillation of wood, comprises a chamber containing a series of interchangeable retorts filled with flanged covers, each retort having an opening in the end to receive a pipe, which passes through the wall of the furnace and is capable of longitudinal movement, so as to permit of its being fitted into the hole in the particular retort to which it belongs. Each pipe has a separate delivery for the by-products escaping from the retort.—D. B.

GERMAN PATENT.

Ammonia; Process and apparatus for the recovery of —— from coke-oven gases. W. Heinemann. Ger. Pat. 166,380, Nov. 25, 1903.

THE patent relates to a process for the recovery of ammonia from coke-oven gases by leading such gases into concentrated acid, provision being made for the continuous removal of the separated tar, which collects on the surface of the acid. By means of a jet of steam, to which sufficient acid may be added to neutralise the ammonia in the gases, the latter are caused to enter the acid-bath at such an angle that they set the supernatant layer of tar in motion. The vessel containing the acid is divided transversely by an overflow device, over which the tar passes into a separate compartment, from which it is withdrawn.—A. S.

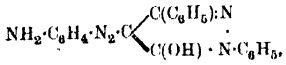
Column still for ammoniacal liquor. C. Francke. Ger. Pat. 169,444, June 4, 1904.

In a column still for ammoniacal liquor, the immersion bells in the still are connected, either singly or in groups, to a kind of frame, which can be raised or lowered from outside the apparatus. By this means the depth to which the bells are immersed in the liquid can be easily regulated, and stoppages avoided.—A. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

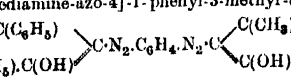
(*Continued from page* 1143.)

Nitration; A new process of ——. O. N. Witt and A. Utermann. Ber., 1906, **39**, 3901—3905.



The method consists in the use of acetic anhydride or glacial acetic acid instead of sulphuric acid as a means of absorbing the water produced in nitration operations. Example: 45 grms. of acetanilide are dissolved in 22 grms. of glacial acetic acid, and to the solution is added a mixture of 23 grms. of nitric acid, sp. gr. 1·5, and 1 grm. of urea (to destroy any nitrous acid) with 23 grms. of glacial acetic acid. After 24 hours 360 grms. of ice are dropped in, and the crude products which separate are treated with a mixture of 1 vol. of 50 per cent. caustic potash, 4 vols. of alcohol, and 1 vol. of water. On filtering, pure *p*-nitroacetanilide remains behind, and the filtrate, after gentle warming to complete the saponification, yields the *o*-nitroaniline. The yield (calculated on the acetyl compounds) was 10·8 grms. of *p*- and 32·8 grms. of *o*-nitroacetanilide. The process is recommended as a very convenient one for the preparation of *o*-nitroaniline on the large scale, being simpler and cheaper than that of Nietzki and Benckiser (this J., 1885, 276).—J. C. C.

b(b)*b'-Disazo-compounds of p-phenylenediamine with heterocyclic components.* C. Bulow and F. Busse. Ber., 1906, **39**, 3861—3868.

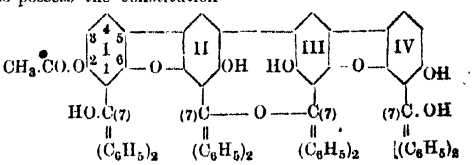


By combining diazotised aceto-*p*-phenylenediamine with benzoylacetic ester in presence of sodium acetate, aceto-*p*-phenylenediamine-azo-benzoylacetic ester

$$CH_3.CO.NH.C_6H_4.N_2.CH(CO_2C_2H_5).CO.C_6H_5$$

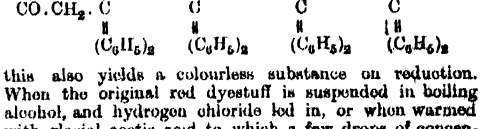
is obtained in yellow needles, m. pt., 95·5° C. Fatty aromatic azo-compounds of this kind are comparable with the corresponding β-naphthol dyestuffs. On boiling with phenylhydrazine in glacial acetic acid solution, this compound gives rise to [aceto-*p*-phenylenediamine-azo-4]-1:3-diphenyl-5-pyrazolone, which crystallises from dilute acetic acid in red needles, and on saponification yields [*p*-phenylenediamine-azo-4]-1:3-diphenyl-5-pyrazolone,

crystallising from alcohol in red-brown needles melting at 208°—209° C. This amino-azo-compound can be further diazotised, and then on combination with aceto-acetic ester in sodium acetate solution, yields 1:3-diphenyl-5-pyrazolone-[4-azo-*p*-phenylenediamine-azo-4]-aceto-acetic ester, which crystallises from alcohol in red needles melting at 195°—196° C., and on condensation with phenylhydrazine gives 1:3-diphenyl-5-pyrazolone-[4-azo-*p*-phenylenediamine-azo-4]-1-phenyl-3-methyl-5-pyrazolone,



crystallising from benzene in brown-red leaflets with a greenish metallic reflex, melting at above 270° C. This disazo-compound dissolves with a deep red colour in concentrated sulphuric acid. It is also obtained by combining diazotised 1-phenyl-3-methyl-5-pyrazolone-[4-azo-phenylenediamine] with benzoylacetic ester and condensing the product with phenylhydrazine.—J. C. C.

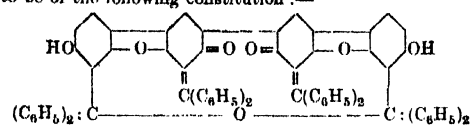
Isorosindone and thiorosindone; Action of hydroxylamine on ——, *and formation of naphthosafranol from isorosindone.* O. Fischer and K. Arntz. Ber., 1906, **39**, 3807—3812.



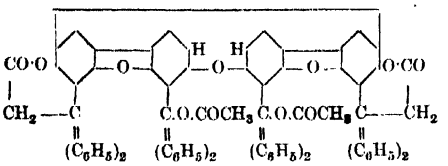
The substance obtained by the action of hydroxylamine on isorosindone, hitherto regarded as isorosindoneoxime, is shown to be *s*-amino-isorosindone. By boiling the diazo-compound of the latter base with alcohol, isorosindone was produced, whilst the amino-compound on being heated with glacial acetic acid and hydrochloric acid under pressure to 180°—190° C. gave rise to oxyisorosindone, which on treatment with caustic potash and methyl- or ethyl iodide yielded the corresponding ether of the isomeric naphthosafranol. As a consequence of these experiments the so-called *ms-o*-tolylisorosindone is now to be regarded as *ms-o*-tolylamnorosindone. By the action of hydroxylamine on thiorosindone a substance of the composition $C_{22}H_{15}ON_3$ is obtained, which is identical with the product of the interaction of hydroxylamine and phenylnaphthophenazonium-6-sulphonic acid. It is not yet possible to say whether this compound is rosindoneoxime or 6-oxamnophenylnaphthophenazonium anhydride. By heating isorosindone with glacial acetic acid and hydrochloric acid to 200° C., oxyrosindone (naphthosafranol) is obtained.—J. C. C.

Benzil with resorcinol; Condensation of ——. *Pt. II. Derivatives of m-tetra-2:6-dihydroxytritanol.* H. von Liebig. J. prakt. Chem., 1906, **74**, 345—419.

By fusing benzil (200 grms.) with resorcinol (160 grms.) in presence of caustic potash or potassium carbonate (200 grms.) at 130°—140° C., a mixture of 10 new compounds results, from which a red dyestuff, $C_{78}H_{54}O_{10}$, is separated by extraction with boiling glacial acetic acid. This is said to possess the constitution—



and is given the name: 2I-acetoxy-*m*-tetra-2:6-dihydroxy-tritanol-6I2II6III2IV-diether-7II7III-anhydride. (The word "tritan" represents the triphenylmethane nucleus $(C_6H_5)_3C$-, "ether" denotes the phenyl ether linking $C_6H_5.O.C_6H_5$, and *o*, *m*, *p* before the Greek numerals tetra, &c., indicate that a direct union takes place between the corresponding number of phenyl groups (in the above case, four) in the *o*-, *m*-, or *p*-position. "Anhydride" indicates the etheric union between the aliphatic carbon atoms, and "anhydro" denotes that water has been eliminated between the groups numbered.) The substance is only sparingly soluble in the usual organic solvents (with the exception of the aliphatic hydrocarbons); its solutions are yellow with a bright green fluorescence. Concentrated solutions of the alkali salts are dark violet-red and do not fluoresce. On dilution, however, an intense green fluorescence is noticed, and the diluted solutions are bluish-red, resembling that of eosin. The red dyestuff is reduced to a colourless substance by zinc and glacial acetic acid, and on being heated alone to 280°—320° C. yields a dark brown compound soluble in chloroform giving a brown solution with green fluorescence, and, according to the author, possessing the constitution—



this also yields a colourless substance on reduction. When the original red dyestuff is suspended in boiling alcohol, and hydrogen chloride led in, or when warmed with glacial acetic acid to which a few drops of concentrated sulphuric acid have been added, the substance is

converted into the red "tritanone other" crystallising from chloroform in red needles, m. pt. 274° C., and stated to be of the following constitution :—

This compound yields a colourless substance on reduction. When either of the two preceding compounds is heated with acetic anhydride and sodium acetate, a blue tetracetyl-derivative is obtained stated to have the formula—

This body yields a deep blue solution in benzene, and melts at about 200° C. A large number of salts, acetyl-derivatives, and addition compounds of these substances is described, and their constitution discussed with reference to the existing theories of colour and fluorescence.—J. C. C.

Dyestuffs of the stilbene group. Part III. A. G. Green and P. F. Crosland. Chem. Soc. Trans., 1906, **89**, 1602—1614.

It has been shown previously (this J., 1893, 146, 837; 1904, 1142) that in the production of stilbene dyestuffs from *p*-nitrotoluene or its ortho substituted derivatives by heating with caustic alkalis, the first step is the formation of unstable and easily oxidisable dinitrosostilbene compounds of the type: $(NO)(X)C_6H_3.CH{:}CH.C_6H_3(X)(NO)$. These nitroso compounds have, in alkaline solution, a deep crimson, violet, or blue colour. In order to ascertain the nature of the change of the nitroso compounds into stilbene dyestuffs on further heating with caustic alkalis, a number of dyestuffs (Stilbene Yellow 8 G and 4 G, Direct Yellow RT, and Mikado Orange) were (1), reduced to diaminostilbenedisulphonic acid by titration with titanium trichloride (see Knecht, this J., 1903, 825; J. Soc. Dyers and Col., 1905, **21**, 292), and the quantity of hydrogen consumed, determined; (2) oxidised with permanganate in cold dilute aqueous solution to aldehydes (see Eng. Pat. 1431 of 1898; this J., 1899, 133), in order to determine the number of ethylene groups. The aldehyde groups produced in (2) were determined by titration with phenylhydrazine; and the aldehydes were isolated and identified. The results obtained, indicate that the second step in the production of stilbene dyestuffs from the intermediate nitroso compounds consists in the oxidation of one nitroso group at the expense of the other, and the union of the remaining nitrogen atoms of two molecules of the nitroso compound to form an azo-group.

$$2\ \begin{matrix}CH.C_6H_3(SO_3Na)NO\\ \ddot{C}H.C_6H_3(SO_3Na)NO\end{matrix}$$

$$\begin{matrix}CH.C_6H_3(SO_3Na)\cdot N & \text{----} & N.C_6H_3(SO_3Na)CH\\ \ddot{C}H.C_6H_3(SO_3Na)(NO_2) & & (NO_2)(SO_3Na)C_6H_3.\ddot{C}H\end{matrix}$$

In the case of the redder yellows and of the orange dyestuffs, the two nitro groups are reduced first to an azoxy-, and finally to an azo-group.

Stilbene Yellow 8G.—The dyestuff was purified by repeated precipitation as the potassium salt, and the latter finally washed with 50 per cent. alcohol. On reduction with titanium trichloride according to Knecht's method (*loc. cit.*), the amount of reducing agent agreed well with that required for the reduction of dinitroazodistilbenedisulphonic acid, and this view was confirmed by the result of the oxidation with permanganate. The aldehydes produced were identified as nitrobenzaldehydesulphonic acid and azobenzaldehydesulphonic acid. Stilbene Yellow 8 G thus consists almost entirely of the sodium salt of dinitroazodistilbenedisulphonic acid, formulated above.

Stilbene Yellow 4 G.—This consists substantially of the same compound as the 8 G brand of dyestuff, but contains in addition a small quantity of the corresponding azoxy compound:

$$\begin{matrix}CH.C_6H_3(SO_3Na).N=N.C_6H_3(SO_3Na).CH\\ \ddot{C}H.C_6H_3(SO_3Na).N\text{—}N.C_6H_3(SO_3Na).\ddot{C}H\\ \qquad\qquad\qquad\qquad\quad \backslash O /\end{matrix}$$

Direct Yellow RT (Direct Yellow, Curcumine S, Sun Yellow, Naphthamine Yellow).—This dyestuff contains considerable quantities of an azomethine compound. After purification, it gave results showing that the pure stilbene dyestuff was the sodium salt of azoxyazodistilbenedisulphonic acid. It was not found possible to effect a separation of the two aldehydes produced on oxidation, but the mixture gave the characteristic colour reactions of azobenzaldehydedisulphonic acid, and on titration with phenylhydrazine gave a result corresponding with that required by a mixture of equimolecular proportions of azobenzaldehydedisulphonic acid and azoxybenzaldehydedisulphonic acid.

Mikado Orange.—Of the various brands of this dyestuff, that marked 3RO appears to be the most completely reduced product, the brands, 4RO and 5RO, being probably mixtures of this with a red dyestuff. It was not found possible to completely free the dyestuff from an accompanying azomethine compound, which was present in large quantities. As the purification progressed, however, the results obtained on reduction of the dyestuff with titanium chloride, and on oxidation, approximated more and more to those required for the alkali salt of disazodistilbenedisulphonic acid,

$$\begin{matrix}CH.C_6H_3(SO_3Na)\,N{:}N.C_6H_3(SO_3Na).CH\\ \ddot{C}H.C_6H_3(SO_3Na).N{:}N.C_6H_3(SO_3Na).\ddot{C}H\end{matrix}$$

From the oxidation products two aldehydes were isolated, of which one proved to be azobenzaldehydesulphonic acid formed from the disazodistilbenedisulphonic acid, whilst the other was probably an oxidation product of the azomethine compound.—A. S.

English Patents.

Sulphine colours [Sulphide dyestuffs]; Preparations of ——. R. B. Ransford, Upper Norwood, Surrey. From L. Cassella und Co., Frankfort on Maine, Germany. Eng. Pat. 7273, March 26, 1906.

The transformation of sulphide dyestuffs into colours which dissolve easily in dilute alkalis may be effected by desiccating their pastes with glucose. The following example illustrates the method of working:—100 kilos. of Immedial Black NG, 40 per cent. paste, are mixed with a concentrated solution of 40 kilos. of glucose, and desiccated in a vacuum, at 140° C. The dried product is readily soluble in dilute alkalis, and dyes cotton direct a black shade. The dyeings are best carried out with the addition of sodium sulphate or chloride.—D. B.

Phenylglycine or its homologues; Manufacture of ——. O. Imray. London. From Farbwerke vorm. Meister, Lucius, and Brüning, Hoechst a/Main, Germany. Eng. Pat. 9700, April 25, 1906.

The process consists in heating nitrobenzene or a homologue with iron and chloracetic acid, *e.g.*, 620 kilos. of nitrobenzene, 1000 kilos. of finely-divided cast iron, and 70 kilos. of aniline are introduced into a vessel provided with an agitator, reflux condenser, and thermometer. The whole is heated to about 70° C., whereupon a solution of 470 kilos. of monochloracetic acid in 1000 litres of water is gradually run in. The chloracetic acid is added in such a manner that the mass may remain boiling. The heating is continued for another couple of hours at 98°—100° C., and the mass is then neutralised with a concentrated solution of sodium carbonate, and distilled with steam, about 70 kilos. of aniline passing over, which can be used again. The mixture is passed through a

filter-press and the residue washed with water. The phenylglycine is separated from the combined filtrate and washings by the addition of the requisite quantity of a mineral acid. The nitrobenzene can be replaced by its homologues.—A. B. S.

Indigo; Manufacture of substances suitable for use in the production of ——. E. C. Schrottky, London. Eng. Pat. 10,506, May 4, 1906.

It has been found that alkaline glucosates or saccharates can be used with great advantage in the process of extracting indigo from the plant. For their production, 100 parts of caustic soda are dissolved in about 200 parts of water, and after bringing the solution to a temperature of 140°—160° F., 100 parts of glucose are gradually added to the mass with constant stirring during a period of 10 minutes, to cause the temperature to rise either spontaneously, or, if necessary, with the aid of heat to 240° F. The resulting solution is employed in the following manner:—For treating 1000 cb. ft. of indigo plants from 40 to 80 lb. are diluted with about 10 times the weight of water, the solution is mixed with the steeping water, and allowed to remain for 16 hours or more in contact with the plants. The steeping liquor is then removed and treated, prior to being heated, with about 40 lb. of caustic soda, after which, and before boiling, 20 lb. of concentrated sulphuric acid, previously diluted with 10 times the weight of water, are added to the indigo fecula.—D. B.

FRENCH PATENTS.

5-Hydroxy-1.2-naphthimidazole-7-sulphonic acid; Production of derivatives of ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 368,297, July 19, 1906.

The derivatives of 1.2-naphthimidazole-5.7-disulphonic acid, obtained by combining a suitable diazo-compound with 2.5.7-naphthylamine-disulphonic acid, diazotising the product, combining with an aromatic aldehyde, and reducing, are converted into the corresponding derivatives of 5-hydroxy-1.2-naphthimidazole-7-sulphonic acid by fusion with an alkali hydroxide. When combined with a diazonium compound, these compounds produce dyestuffs which dye unmordanted cotton directly, in a variety of shades from red to blue. (Compare Eng. Pat. 11,759 of 1905; this J., 1906, 215.)—T. F. B.

Dyestuff; Process for preparing a new orange monoazo —— Act.-Ges. f. Anilinfabr. Fr. Pat. 368,259, July 21, 1906.

The combination of diazotised *o*-chloro-*p*-nitraniline with β-naphthol gives rise to a dyestuff which produces orange shades when dyed on textile fibres. The dyestuff may, when desired, be produced on the fibre in the same manner as *p*-Nitraniline Red, or it may be formed in presence of the various compounds necessary for lake formation. Both the dyeings and the lakes obtained, are said to be extremely fast to light.—T. F. B.

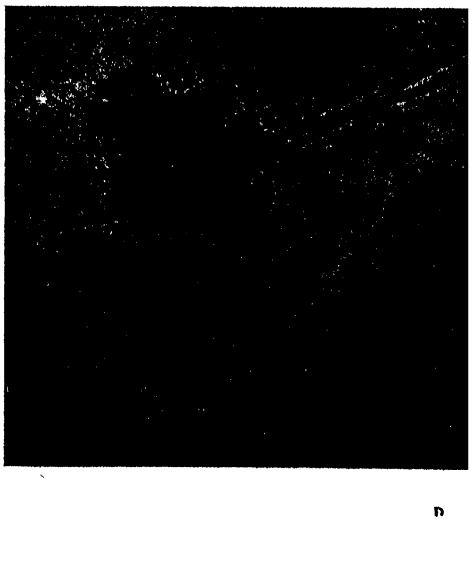
V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 1145.)

Fibres in a mixed fabric; Identification and counting of the various ——. O. Lecomte. J. Pharm. Chim., 1906, **24**, 447.

One hundred sq. cm. of the bleached fabric are soaked in 30 c.c. of 10 per cent. nitric acid until saturated. Thirty c.c. of a 5 per cent. sodium nitrite solution are then added a little at a time during three minutes. The diazotisation is completed in 10 minutes, and the fabric is well washed with water for two minutes and then cut in halves. One portion is placed in 40 c.c. of an alkaline solution of plumbite and naphtholate of soda, and the other portion in 40 c.c. of an alkaline solution of plumbite and resorcinate. This operation should be carried out below 20° C. At the end of two hours the operation is terminated. The two pieces are well washed with water and then soaked for five minutes in a 5 per cent. solution of hydrochloric acid, and finally well washed and dried in the dark. In the portion treated with plumbite and naphtholate, the silk threads appear a rose-red, the wool black, and the vegetable fibres white. In the other portion the silk appears orange, and the wool and vegetable fibres the same as with the naphtholate.—A. B. S.

Carbonising with bisulphate of soda. Spennrath. Oesterr. Wollen und Leinen Ind., 1906, 962. J. Soc. Dyers and Col., 1906, **22**, 383.



The goods are impregnated with a solution of sodium bisulphate at 10° T., and are left in the bath for a somewhat longer period than when sulphuric acid is used. After squeezing, the material is dried in a stove at 100° C., whereby, it is stated, the vegetable fibres are disintegrated but not blackened. The process would appear, therefore, to be specially suitable for white or light-coloured goods, and is also stated to be very advantageous for loose wool. For neutralising, a "soda solution" of not more than 2° T. is employed. The great advantage of carbonising with sodium bisulphate is said to be that the "nature" of the wool is preserved, especially with regard to tenacity, softness, and milling qualities.—A. S.

Antimonine [*Antimony lactate*] J. C. Oxley. J. Soc. Dyers and Col., 1906, **22**, 369—370.

The author points out the advantages of antimonine over other antimony mordants (this J., 1900, 1107). In preparing the mordant, antimonine is first boiled with very little water; about 2 galls. of acetic acid are added per 1000 galls. of mordant liquor. It is stated that the antimony is completely exhausted from the bath, and the shades obtained are faster and deeper than those produced with tartar emetic or antimony salts (antimony fluoride and ammonium sulphate). Antimonine is stated to be specially suitable for darkening with iron salts, and for dyeing half-silks. It is also useful in calico printing, a quantitative precipitation of the tannin being obtained; it does not crystallise out from the printing paste.—A. S.

Silk; Curling and fraying of dyed ——. A. Sansone and R. Sansone, jun. Rev. Gen. Mat. Col., 1906, **10**, 354—362.

The authors give an abstract of a paper published by the *Laboratoire d'études de la Soie de Milan*. The curling and fraying out of silk during the processes of manufacture and dyeing have been observed for many years, and a number of attempts have been made to explain the cause. The

defect shows itself by the presence of a number of little knots or bundles of very fine filaments which are irregularly distributed and appear of a lighter colour than the remainder of the thread or the surrounding fabric. The diameter of these fine filaments is sometimes less than one-tenth of that of the single degummed ordinary fibre. These twisted filaments are called "flocons" or "pelotons," and, as they consist of fibroin, attract colouring matters well, but appear lighter than the main thread owing to their extreme fineness. When the ordinary raw silk fibre or "bave" has had its sericin removed, the single fibres or "brins" frequently exhibit irregularities The fibroin appears to be swollen up in places, and these places frequently show a striated appearance and even longitudinal fissures. These fissures and the division of the fibre into filaments can also be obtained by chemical and mechanical means, and, as a result, it is concluded that the fibroin fibre is not a single, continuous, homogeneous mass, but consists of a bundle of very fine filaments which can become separated by certain treatments and then become entangled together, giving rise to "flocons." (see figure) The authors state that all silks are subject to this "fraying," the tendency to fray being influenced by the breed, method of culture, and diseases of the silk worm, and also by the degumming, dyeing, and mechanical operations to which the silk is subjected. The formation of "flocons" is not observed in raw silk, but only appears after degumming The amount of fraying has been measured by the number of knots in a length of 1000 m of the thread. By this method it was found that a silk degummed once in a 3 per cent soap solution showed from 110—155 knots per 1000 m, whilst after a second treatment the number had increased to 414—559. With an alkaline soap containing 0·5 per cent of caustic soda, the number after four treatments was 5540 The presence of an excessive quantity of sericin in the boiling-off bath favours the formation of "knots." The mechanical treatment of the fibre, and especially the method of degumming, has a great influence on the fraying. Silk degummed at the boil followed by "chevillage" showed 1254 per 1000 m The same silk degummed on a water-bath showed 649, whilst on bobbins it only showed 16. These figures show that the fibre should be moved as little as possible during the degumming. Weighted silk shows a large increase in the number. In the old method of degumming in sacks there was little formation of "flocons," as the silk did not move For use on the large scale the authors recommend an apparatus in which the silk should remain at rest whilst the scouring liquid should be circulated by means of a pump It is also shown that the best results are obtained by degumming at a moderate temperature.—A. B. S

Indigo; Action of chlorates on —— on the fibre. A. A. Radkiewicz. Z. Farben-Ind., 1906, 5. 422-425, 436—441

The author has studied the influence of the chlorates of certain metals belonging to each group of the periodic system, used in conjunction with vanadium salts or potassium ferricyanide for discharging indigo on the fibre. The nature of the chlorate exerts a very distinct influence on the process, and the presence of vanadium salts has a deteriorating action on the fibre. When potassium ferricyanide is used as oxidising agent, the chlorates examined can be arranged in the following series according to their action on indigo, those exerting the greatest action coming first Copper, in combination with chloric acid, shows the greatest destructive effect on both indigo and the fibre Then follow iron, aluminium, and calcium chlorates, which give a sharp design, but rot the fibre. Sodium and barium chlorates, the former with ammonium ferricyanide and the latter with ammonium and potassium ferricyanides, yield a good white discharge, and the fibre is not weakened. Potassium and ammonium chlorates give rather a weaker discharge, and are therefore not suitable for dark shades or for very heavy materials. The strength of the fibre is not affected by potassium chlorate and ammonium ferricyanide, or ammonium chlorate and potassium ferricyanide. Chromium, magnesium, and manganese chlorates give a poor result, and chromium and nickel chlorates produce hardly any discharge, and the weakening of the fibre is appreciable. Zinc chlorate does not act on indigo. The best results were obtained with a mixture of ammonium ferricyanide and sodium chlorate. The chlorate is dissolved in water and mixed cold with the solution of ammonium ferricyanide; a small quantity of an organic acid (citric or tartaric) is then added. In an example, 400 grms. of crystallised sodium chlorate, 200 grms. of ammonium ferricyanide solution of 21° B., 60 grms. of citric acid, and 1000 grms. of water were used The mixture is allowed to stand for one to two days in a cool place, when the excess of salts crystallises out After filtering, the solution is mixed in the cold with the thickening material (tragacanth, 1:1). The goods, after drying, are steamed for three to four minutes and then soaped at 50° C. The advantages of this method are that the discharge can be kept for a week, no crystals separate on the rollers of the printing machine, a three to four minutes' steaming is sufficient, washing in hot caustic alkali is avoided, the fibre is in no way weakened, and the chemicals used are comparatively cheap.—J. C. C.

English Patents.

Leaf or fabric; Thin ——, and method of making the same. W. A. Ker, Brooklyn, U.S.A. Eng. Pat. 13,005, June 5, 1906

See U.S. Pat. 826,781 of 1906; this J., 1906, 1040.—T. F. B

Wool; Process for cleansing —— and recovering the grease and the solvent used. A. P. Quackenbos, Boston, U.S.A. Eng. Pat 16,159, Aug. 8, 1905.

See U.S Pat. 796,530 of 1905; this J., 1905, 966.—T. F. B.

Sterilisation [Electrolytic] of wool, cotton, rag, hair, fibres, or similar material for prevention of anthrax. I Ickringill, Keighley, York. Eng. Pat. 23,345. Nov. 14, 1905.

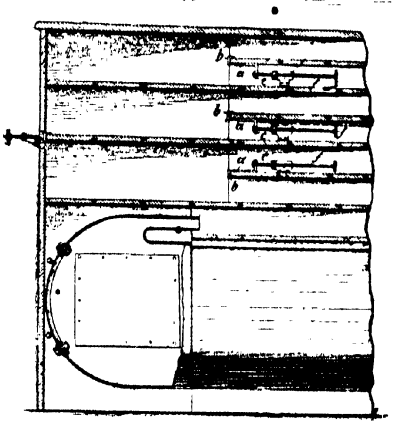
The material is placed in a tank containing a suitable liquid such as sulphuric acid of 1°—5° T., and an electric current is passed through until the material is sterilised. —A. B. S.

Dyeing apparatus. P. Klug, Krummitschau, Saxony Eng. Pat. 23,050, Nov. 10. 1905.

See Fr. Pat. 359,344 of 1905; this J., 1906, 373.—T. F. B

Dyeing acetylated cellulose or artificial silk made therefrom, Process for ——. C. D. Abel, London From Act.-Ges f. Anilinfabr., Berlin. Eng. Pat. 1939, Jan 25, 1906.

See Fr. Pat. 362,721 of 1906; this J., 1906, 692.—T. F. B



Fabrics; Apparatus for the wet treatment of ——. G. R Richter. Seifhennersdorf, Germany. Eng. Pat. 19,182. Aug. 28, 1906.

Claim is made for a machine for the dyeing, &c., of textile fabrics in the open width. For use with fabrics of various widths, a number of "liquor troughs" of various lengths are provided. These are similar in shape and can be fitted one within the other, so that the trough most suitable for the particular fabric may be readily selected, thus economising the liquor. Each trough contains steam pipes, guide rolls, &c.—A. B. S.

United States Patent.

Drying apparatus [for textile fabrics]. J. Tattersall. Enschede, Netherlands. U.S. Pat. 835,168, Nov. 6. 1906.

The apparatus consists of a series of drying chamber, separated by floors of transversely arranged boards with adjusting devices for pressing the boards laterally together, each device comprising a bent piece, *a*, having a part, *b*, adapted to engage the edge of the board, and a part, *c*,

and a screw, *f*, engaged with part *e*, by means of a pivot, and a fixed nut engaged by said screw.—D. B.

FRENCH PATENTS.

Broom, Process for obtaining textile fibres from ——. E. Genin and H. Colomb. Fr. Pat. 361,805, Sept. 29, 1905.

THE green broom is boiled for about an hour in a 2 per cent. solution of crystal sodium carbonate in order to separate the bark from the wood. It is next soaked in cold water for two hours, and then, after draining, it is ground in a revolving mill, similar in principle to a mechanical kneading trough, in order to detach the fibre. The material is then passed between two or more drums covered with teasles and combs in order to separate the fibre.—A. B. S.

Silk, artificial, Production of —— *from collodions made with acetone or ethyl acetate.* J. A. E. H. Boulher. Fr. Pat. 368,190, July 19, 1906.

ACETONE or ethyl acetate alone are not suitable for use in dissolving the nitrated cotton, as, owing to the fact that they have a rather low vapour tension, they evaporate too slowly from the silk thread, and so do not give a satisfactory product. This defect is removed either by raising the temperature at which spinning is carried on, or else by the addition of a small quantity of a liquid, such as ether, which has a high vapour tension. The absence of water is also of great importance, as small traces lower the vapour tension of the solvent considerably.—A. B. S.

Imitation-fabrics; Production of —— *from viscous materials* [*collodion, &c.*]. E. Dumat. Fr. Pat. 368,393, July 27, 1906.

THE viscous material is forced under a suitable pressure through a slit the length of which is equal to the desired width of the fabric and the breadth of which is the same as the required thickness of the fabric. In front of, and in contact with this opening works a plate with openings of a particular shape depending on the pattern desired. This works to and fro in front of the slit, and so cuts the flat sheet of viscous material into a definite pattern. The sheet so formed is received on a drum or endless band, and dried in a suitable manner.—A. B. S.

Scouring of old textile materials, cotton waste, &c. E. Favier. Fr. Pat. 368,036, July 13, 1906.

OLD materials containing cotton, linen, hemp, jute, ramie, or other vegetable fibres, are treated with carbon tetrachloride in order to eliminate fatty or resinous matters, and then with soluble sulphites to remove pectic matters and leave the pure cellulose.—A. B. S.

Bleaching wool; Process and apparatus for [*electrically*] ——. G. Pansa and A. Romberg. Fr. Pat. 368,280, June 18, 1906.

THE wool is placed in the middle portion of a spherical vessel which is divided into three parts by two parallel, perforated plates, and can be revolved on an axis parallel to the perforated partitions. The vessel is closed, some suitable solvent for fatty matters, such as carbon bisulphide, is run in, and the vessel slowly revolved on its axis so as to cause a circulation of the solvent through the wool. When the process is completed, the solvent is run off and the portion adhering to the wool is removed by a vacuum pump. To bleach the wool it is placed in a vessel the top and bottom of which form two electrodes, and are connected with a suitable source of electricity. The cathode is a plate of lead, and the anode a plate of retort carbon, graphitised wood charcoal, or, preferably, platinised zinc. The vessel is filled with a dilute solution containing chloride of lime, ferrous chloride, sodium thiosulphate, and a little sulphuric acid to give conducting power to the bath. After allowing the current to pass for some few hours, the wool is said to be bleached.—A. B. S.

Spindle for bobbin-dyeing. Soc. Anon. des Usines de Navarre. Fr. Pat. 367,859, July 7, 1906.

THE upper end of the tube, *c*, (Fig. 1), through which the dye liquor is introduced, is formed with grooves, *b*, and

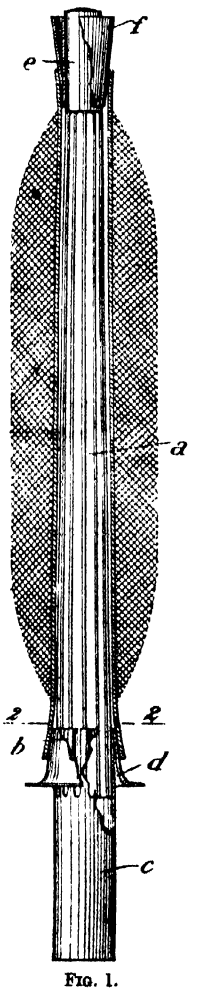


FIG. 1.

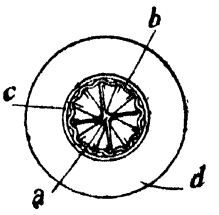

FIG. 2.

into these are soldered the radial wings of a metallic rod, *a* (Fig. 2). The upper end of *a* is fitted into a closed cylindrical tube, *e*, a cone, *f*, slipping easily over this tube and closing the end of the bobbin. The lower end of the latter is closed by a cone, *d*, soldered to the tube, *c*.—B. N.

Dyeing spindle with fibrous cover. O. Bauer and K. Suttner. Fr. Pat. 368,355, July 25, 1906.

The spindle consists of three wires, which meet at one end in a cap and are fastened at the other into a metal tube furnished with a screw for connecting with the dyeing apparatus. The wire support is covered with a tube of some thin fabric which slips on the wire frame and is held there by friction. The thread to be dyed is wound on the spindle, and the dye is forced through in the usual manner. After dyeing, the tube can be removed with its bobbin of cotton.—A. B. S.

Dyeing apparatus which can be taken to pieces. J. Schmitt and E. Handschin. Fr. Pat. 368,485, July 28, 1906.

The machine consists of a cylinder with perforated wall, which is fixed by means of keys on a circular bed-plate. The cylinder consists of four quadrants which are also held together by keys. These quadrants can be easily removed by means of handles on releasing the keys. The perforated cylinder is placed inside another unperforated cylinder, which can be taken to pieces in a similar manner. A perforated pipe connected with the supply of dye liquor passes centrally through the middle vessel. The material to be dyed is placed inside the middle vessel, and a suitable top is screwed down on to it. After the material has been dyed in the usual manner by the circulation of the dye liquor, the two cylinders are taken to pieces, and the dyed materials removed. A. B. S.

Sulphide colours; Process of dyeing by means of ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 367,921, July 9, 1906. Under Int. Conv., June 28, 1906.

In dyeing with sulphide colours, ammonia or ammonium salts are added to the dye-bath in addition to alkali sulphides.—B. N.

Ossein; Preparations and applications of ——. A. Helbronner and E. A. Vallée. Fr. Pat. 361,796, Sept. 26, 1905. XIV., page 1227.

German Patents.

Wool and other animal fibres; Process for altering the affinity of —— for dyestuffs by treatment with concentrated sulphuric acid. M. Becke and A. Beil. Ger. Pat. 168,026, Oct. 28, 1902.

Wool is treated in sulphuric acid baths of successively diminishing concentrations, starting with acid of about 66° B., and finishing with very dilute acid or water. After this treatment, it is stated, the wool has entirely lost its affinity for the usual acid dyestuffs, but can be readily dyed with basic dyestuffs.—T. F. B.

Wool; Process for partially altering the affinity for dyestuffs of a spun fabric containing ——. M. Becke and A. Beil. Ger. Pat. 168,113, Feb. 28, 1903.

Fabrics containing wool or other animal fibre are treated or printed, in the desired portions, with sulphuric acid (64°–66° B.), thickened with kaolin or the like; this has the effect of rendering the portions treated capable of being dyed with basic dyestuffs, whereby a variety of effects may be produced. The fabric must be thoroughly washed after the treatment.—T. F. B.

Aniline Black on wool; Process for producing ——. G. Bethmann. Ger. Pats. 170,228, March 31, 1904, and 171,351, May 7, 1904.

In Eng. Pat. 26,962 of 1905 (this J., 1906, 753) the words "sodium chloride" should be replaced by "sodium chlorate." The wool may also be treated, before dyeing, with a solution of aluminium chloride, magnesium chloride, or similar salt capable of forming an insoluble salt with the organic compounds in the wool.—T. F. B.

Dyeings and printings with basic dyestuffs; Process for rendering —— fast to light. Anilinfarben und Extrakt Fabrik. vorm. J. R. Geigy. Ger. Pat. 169,923, April 12, 1904.

The fastness to light of dyeings and printings with basic dyestuffs is greatly increased by a subsequent treatment with a solution of glucose and a copper salt (*e.g.*, the sulphate). Such treatment gives results fully equal to those obtained with zinc polyglucosate (Ger. Pat. 141,508), with the advantage that the solution containing a copper salt does not become dark in colour on keeping.—T. F. B.

Dyeings produced with "chroming" dyestuffs; Improvement of ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 166,351, Nov. 1, 1904.

Faster dyeings with dyestuffs which can be chromed are obtained by adding to the mixture of dyestuff and chromium salt a substance which is easily oxidised, or readily forms lakes, *e.g.*, gallic acid, tannin, anthranilic acid, qumol, α-naphthol, dihydroxynaphthalenes, or aminonaphthols; or these substances may, if desired, be used subsequent to the dyeing process. The dyeings are said to be exceptionally fast to fulling and water; the fastness to alkalis and soaping is also much increased.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(*Continued from page* 1093.)

German Patent.

Wood; Process for producing a dark colour on ——, without injuring it. Chem.-Techn. Laboratorium E. Bartels. Ger. Pat. 170,565, Nov. 7, 1905.

Dry or green wood is heated in a closed vessel, to between 200° and 350° C. in a mass of a liquid hydrocarbon, animal oil, mineral oil, or vegetable oil, of high boiling point, until the desired colour is reached; the temperature should be sufficiently high to remove the sap. When the process is finished, the liquid is run off, and the wood kept in the vessel until cool.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 1147.)

Oxides, Behaviour of metallic —— at very high temperatures. F. O. Doeltz and C. A. Graumann. Metallurgie, 1906, **3**, 212—216, 233—238, 372—375, and 406—408. Science Abstracts, 1906, **9A**, 587.

The experiments were made with zinc oxide, cadmium oxide, and lead oxide. For the lower temperatures the oxides were heated in a platinum boat, but above 1,400° C. the micro-furnace of Doeltz was employed. This consists of an electrically-heated (5 amps. at 1—2 volts) horizontal platinum wire 0·15 mm. diameter and 6 to 8 mm. long. The material to be examined is spread upon the wire, and observed through a microscope. Below 1200° zinc oxide loses practically nothing, the loss gradually increasing (1 per cent. at 1300°, 13 per cent. at 1400°, in two hours) until at 1710° C. immediate evaporation takes place with formation of needle-shaped crystals. The behaviour of the cadmium and lead oxides was examined up to 1000° C.

Platinised electrodes for alkali chloride electrolysis; Application of grey ——. J. W. Goibel. XIA., page 1224.

ENGLISH PATENTS.

Sodium nitrate; Dissolving plant for the recovery of —— from caliche. W. C. Fairweather, London. From J. R. Beaver and R. de Nordenflycht, Valparaiso, Chile. Eng. Pat 7478, Mar. 28, 1906.

THE "dissolver" or boiling tank, for the recovery of sodium nitrate from caliche, is an upright cylinder having conical ends, the top of the upper cone being formed with a cylindrical collar having an air-tight balanced door. The lower conical end is closed by a perforated bottom formed of two semi-circular discs, capable of being revolved, below which is a receptacle closed by an air-tight door similar to that above. An open tube leads upwards from the receptacle, outside the apparatus, nearly to the top of the dissolver, through which, by means of a pump, air is drawn so as to agitate the charge of caliche resting on the false bottom, in presence of water or solution. The dissolvers are arranged horizontally in a battery of five, and from the lower receptacle of each, a valved tube passes into a horizontal pipe through which, by suitable adjustment of valves, any dissolver may independently be charged with liquid, or be placed in connection with any other dissolver. In practice, the weak liquors from one end of the battery pass through successive elements of the same, to emerge from the last at full strength. Each dissolver is provided with a steam coil, and arrangements are made whereby primary or secondary steam may be supplied as needed. The apparatus includes a steam boiler, a settling and "relave" tank, valved pipe connections between the tanks and the dissolvers, a source of water supply, and pipes for waste liquor, ordinary water, and "relaves" or second, or weak washings, connected to the upper conical ends of the dissolvers, besides accessory details.—E. S.

Iodine; Method of extracting — — from liquids containing compounds of iodine. Soc. Franç. La Norgine, Paris. Eng. Pat 9621, April 24, 1906. Under Int. Conv., May 23, 1905.

SEE Fr. Pat. 361,499 of 1905; this J., 1906, 864.—T. F. B.

FRENCH PATENTS.

Sulphur dioxide; Process for the utilisation of the —— produced in the smelting of antimony. G. R. M. Sweeting. Fr. Pat. 361,808, Oct. 3, 1905. X., page 1224.

Nitric acid; Manufacture of —— by means of atmospheric air. Chem. Fabr. Gladbeck G. m. b. H. First Addition, dated July 13, 1906, to Fr. Pat. 341,109, March 10, 1904 (this J., 1904, 823).

BY the present Addition the scope of the main patent is made to include, as the source of nitric acid, any mixture whatever of oxygen with nitrogen.—E. S.

Aluminates, hydrochloric acid, and sodium carbonate; Process for the production of —— by means of aluminous materials. P. Klein. Fr. Pat. 368,106, July 17, 1906.

BAUXITE, clay, or other aluminous bodies, in fine powder, are added to sodium chloride melted in a closed vessel, connected with apparatus for condensing the hydrochloric acid evolved. Superheated steam is injected into the melt during the process. The mass is lixiviated, and carbon dioxide is passed into the cleared solution of sodium aluminate obtained, from which the aluminium hydroxide precipitated is removed, the filtrate being evaporated to recover sodium carbonate. The process may be repeated with the aluminium hydroxide thus obtained, in which case the injection of steam, except towards the end of the process, may be dispensed with.—E. S.

Gases [hydrochloric acid] and liquids; Purification of —— [from arsenic, &c.]. Verein Chem. Fabr. in Mannheim. Fr. Pat. 368,452, July 27, 1906.

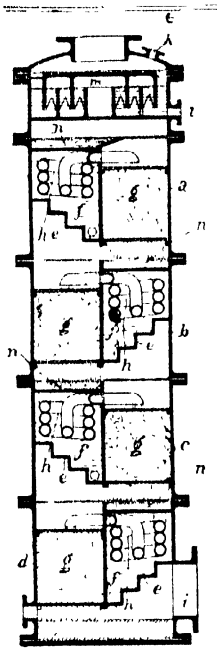
HYDROCHLORIC acid gas, as produced in the manufacture of sodium sulphate [salt-cake], after being cooled and dried, and in some cases filtered through coke, is brought into intimate contact in a tower or otherwise, with an oil, preferably a mineral oil, or oil from lignite tar, such oil readily absorbing arsenic chloride without itself becoming chlorinated, provided the temperature be kept low. The oil thus used is recovered, and may be fitted for re-use by washing with lime water, and lastly with hydrochloric acid. Ordinary liquid hydrochloric acid may be freed from arsenic by agitating it with the oil in suitable proportion. To free sulphuric acid from arsenic, hydrochloric acid is added to it, in order to convert any arsenic present into chloride, when the arsenic chloride may be dissolved out by the oil treatment, as already described. —E. S.

Antimony oxides; Preventing the formation of crystallised oxides in the manufacture of — —. H. L. Herrenschmidt. Fr. Pat. 368,037, April 10, 1906.

BRICKWORK and masonry are replaced by sheet or cast-iron apparatus in the chambers and adjuncts used for collecting the antimony oxides, whereby quick cooling is insured, and the formation of crystallised oxides is prevented.—E. S.

Sulphates [Copper sulphate]; Manufacture of metallic ——. H. Abraham. Fr. Pat. 367,947, July 10, 1906.

THE invention is described with reference to obtaining copper sulphate from the sulphide, which latter is granulated and submitted to the action of a mixture of nitric and sulphuric acids with water. The nitrogen oxides evolved are led away to be converted, by air and water or steam, into nitric acid for use over again; and the nitrogen remaining after absorption of the oxygen of the air, may, if desired, be collected and utilised. The copper sulphate solution obtained, after separation from the sulphur set free, is set to crystallise, and the mother liquor is treated for the recovery of precious metals by immersing in it pairs of plates of copper and silver, in metallic contact, when it is stated the precious metals deposit chiefly on the silver plate.—E. S.



Hydrogen peroxide solutions; Stable ——. W. Heinrici. First Addition, dated July 4, 1906, to Fr. Pat. 356,880, Aug. 8, 1905 (this J., 1906, 19). Under Int. Conv., Aug. 28, 1905.

ACID solutions of hydrogen peroxide are rendered comparatively stable by the addition of a small proportion of an amide, imide, or acetyl derivative of an aromatic base, and derivatives of organic compounds of ammonia. The use of phenacetin for the stated purpose is specially indicated.—E. S.

GERMAN PATENTS.

Absorption tower for sulphuric anhydride. Dr. Schlamp vom Hofe und Co., Ges. für Einrichtung von Säurefabriken m.b.H. Ger. Pat. 166,599, June 22, 1904.

THE tower is constructed in sections (*a*, *b*, *c*, *d*, see figure) each of which is divided by a partition into a cooling chamber, *f*, and an absorption chamber, *g*, disposed as shown in the illustration. The cooling chambers have their bottoms shaped in the form of steps, *e*, and are provided with hollowed covers, *n*; in each chamber is a coil, *h*, leading from the cover, and opening above the adjacent absorption chamber. The plates forming the top and bottom of the absorption chambers are perforated. Above the upper section of the tower is a cover, *m*, having inlets, *k*, *l*, for the sulphuric acid used as absorbing agent; the walls of the cover are cut away in the form of teeth

to form a mixing chamber, which communicates with the upper section of the tower.—A. S

Kieserite ; Process for obtaining —— from a mixture of kieserite and rock salt. Gewerkschaft Carlsfund. Ger. Pat. 166,187, Jan. 12, 1904

THE mixture of kieserite and rock salt is treated in a solution more or less saturated with common salt The minerals disintegrate, and the resulting crystalline mass is separated into its constituents by sifting The crystals of rock salt cannot dissolve in the solution, and they can be separated from the kieserite crystals on account of their larger size.—A. S.

Potassium chloride ; Process of obtaining —— from crude potassium salts. J. Maurer. Ger Pat 166,558, June 1, 1904.

THE hot solution (at 90°—100° C.) of the crude salts is run into the first crystallising vessel, and cooled to from 15°—30° C. ; during the crystallisation of the potassium chloride, fresh hot solution is run in When the crystallisation is complete, the cool (15°—30° C.) mother liquor is run into a second crystallising vessel, wherein it is heated to about 80° C., and a quantity of crystallised potassium chloride added to facilitate the separation of the potassium chloride still contained in the mother liquor. The mother liquor from this vessel is mixed with a further quantity of fresh hot (90°—100° C.) solution of crude potassium salts, and the operations described are repeated. —A. S.

Nitrite ; Process for the manufacture of ——. M. Binsfeld. Ger. Pat 168,450, Sept. 1, 1904.

THE production of nitrite by the reduction of alkali nitrate with zinc and small quantities of ammonia is already known. The author finds that much better yields are obtained in less time by the use of a considerable excess of ammonia.—A. S.

Ammonium nitrate free from nitrite ; Process for the manufacture of ——. J. Rudeloff. Ger. Pat. 166,427, Sept. 4, 1904.

IN the denitration of the spent acid from the nitration of glycerin, cellulose, &c., the mixed acid is heated in a suitable vessel, and the nitric acid vapours are expelled by steam or hot air. It is found that these vapours may be suitably utilised for the manufacture of ammonium nitrate. The hot vapours are treated with ammonia solution, and the resulting solution of ammonium nitrate is concentrated in pans heated by the residual sulphuric acid from the denitrating apparatus. The ammonium nitrate is then separated by crystallisation.—A. S.

Selenium ; Process for obtaining pure —— from "chamber mud." H Koch. Ger. Pat. 167,457, Dec. 2, 1903.

THE mud obtained from lead chambers used for the manufacture of sulphuric acid, is heated moderately with sulphuric acid and potassium permanganate, some sodium chloride is added, the solution is diluted and filtered, and the selenium precipitated from the solution by reducing agents according to known methods. Care must be taken not to add too much permanganate, otherwise explosions may occur. The selenium separates in the cold as a red, amorphous powder, which on warming the solution melts together to coarse lumps, which can be removed by ladles without filtration —A. S.

Carbon dioxide absorption apparatus. E. Chur. Ger. Pat. 166,973, April 28, 1905.

THE absorption vessel is divided into rectangular chambers by vertical partitions The gases containing carbon dioxide are introduced to the chambers through immersion-bells, and the chambers are so connected that the absorbing liquid (milk of lime) follows a tortuous course, in order that efficient washing of the gases may be attained without the bells being immersed deeply in the liquid. Baffle-plates may be arranged parallel to and along both sides of the immersion-bells in order to ensure good contact between the gases and the milk of lime – A. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 1148.)

Glass ; Electrically-conducting ——. C E. S Phillips. Oesterr Zeits. Elektrotechn. und Maschinenb., 1906, **24**, 811. Chem.-Zeit., 1906, **30**, Rep., 392.

THE glass is prepared from a mixture of 32 parts of sodium silicate and 8 parts of calcined borax ; an addition of 1·25 parts of flint glass improves the surface and the durability of the resulting glass The glass melts at a low temperature, and can be easily formed into sheets, rods, and threads. It has a sp. gr. of 2·49, is harder than ordinary glass, and has an electric conductivity 500 times greater. It is impermeable to ultra-violet rays, but allows Röntgen rays to pass ; it does not exhibit fluorescence under the influence of cathode rays. In the powdered condition it can be fused on to copper, and remains adherent on cooling.—A. S.

FRENCH PATENTS.

Glass-furnace. C. Krug. Fr. Pat. 368,208, July 19, 1906.

THE glass-furnace described has no hearth, and is heated by one or more burners situated at one end, from which liquid fuel mixed with air or oxygen is sprayed into the furnace. The burners are placed so that the flame does not impinge directly on the glass to be melted. The resulting products of combustion escape through openings placed preferably at the other end of the furnace.—A. G. L.

Ceramic product. Méran Frères. Fr. Pat. 361,814, Oct. 6, 1905.

SEE U.S. Pat. 827,550 of 1906; this J., 1906, 885.—T. F. B.

Food products; Standards of purity for ——. XVIIIA., page 1229.

ENGLISH PATENTS.

Sodium nitrate; Dissolving plant for the recovery of —— from caliche. W. C. Fairweather, London. From J. R. Beaver and R. de Nordenflycht, Valparaiso, Chile. Eng. Pat 7478, Mar. 28, 1906.

THE "dissolver" or boiling tank, for the recovery of sodium nitrate from caliche, is an upright cylinder having conical ends, the top of the upper cone being formed with a cylindrical collar having an air-tight balanced door. The lower conical end is closed by a perforated bottom formed of two semi-circular discs, capable of being revolved, below which is a receptacle closed by an air-tight door similar to that above. An open tube leads upwards from the receptacle, outside the apparatus, nearly to the top of the dissolver, through which, by means of a pump, air is drawn so as to agitate the charge of caliche resting on the false bottom, in presence of water or solution. The dissolvers are arranged horizontally in a battery of five, and from the lower receptacle of each, a valved tube passes into a horizontal pipe through which, by suitable adjustment of valves, any dissolver may independently be charged with liquid, or be placed in connection with any other dissolver. In practice, the weak liquors from one end of the battery pass through successive elements of the same, to emerge from the last at full strength. Each dissolver is provided with a steam coil, and arrangements are made whereby primary or secondary steam may be supplied as needed. The apparatus includes a steam boiler, a settling and "relave" tank, valved pipe connections between the tanks and the dissolvers, a source of water supply, and pipes for waste liquor, ordinary water, and "relaves" or second, or weak washings, connected to the upper conical ends of the dissolvers, besides accessory details.—E. S.

Iodine; Method of extracting — — from liquids containing compounds of iodine. Soc. Franç. La Norgine, Paris. Eng. Pat 9621, April 24, 1906. Under Int. Conv., May 23, 1905.

SEE Fr. Pat. 361,499 of 1905; this J., 1906, 864.—T. F. B.

Oxygen gas; Compositions of matter for use in the generation of — —. G. F. Brindley, Niagara Falls, U.S.A. Eng. Pat. 11,981, May 22, 1906. Under Int. Conv., April 14, 1906.

SEE Fr. Pat. 366,526 of 1906; this J., 1906, 1045.—T. F. B.

FRENCH PATENTS.

Sulphur dioxide; Process for the utilisation of the —— produced in the smelting of antimony. G. R. M. Sweeting. Fr. Pat. 361,808, Oct. 3, 1905. X., page 1224.

Nitric acid; Manufacture of —— by means of atmospheric air. Chem. Fabr. Gladbeck G. m. b. H. First Addition, dated July 13, 1906, to Fr. Pat. 341,109, March 10, 1904 (this J., 1904, 823).

BY the present Addition the scope of the main patent is made to include, as the source of nitric acid, any mixture whatever of oxygen with nitrogen.—E. S.

Aluminates, hydrochloric acid, and sodium carbonate; Process for the production of —— by means of aluminous materials. P. Klein. Fr. Pat. 368,106, July 17, 1906.

BAUXITE, clay, or other aluminous bodies, in fine powder, are added to sodium chloride melted in a closed vessel, connected with apparatus for condensing the hydrochloric acid evolved. Superheated steam is injected into the melt during the process. The mass is lixiviated, and carbon dioxide is passed into the cleared solution of sodium aluminate obtained, from which the aluminium hydroxide precipitated is removed, the filtrate being evaporated to recover sodium carbonate. The process may be repeated with the aluminium hydroxide thus obtained, in which case the injection of steam, except towards the end of the process, may be dispensed with.—E. S.

Gases [hydrochloric acid] and liquids; Purification of —— [from arsenic, &c.]. Verein Chem. Fabr. in Mannheim. Fr. Pat. 368,452, July 27, 1906.

HYDROCHLORIC acid gas, as produced in the manufacture of sodium sulphate [salt-cake], after being cooled and dried, and in some cases filtered through coke, is brought into intimate contact in a tower or otherwise, with an oil, preferably a mineral oil, or oil from lignite tar, such oil readily absorbing arsenic chloride without itself becoming chlorinated, provided the temperature be kept low. The oil thus used is recovered, and may be fitted for re-use by washing with lime water, and lastly with hydrochloric acid. Ordinary liquid hydrochloric acid may be freed from arsenic by agitating it with the oil in suitable proportion. To free sulphuric acid from arsenic, hydrochloric acid is added to it, in order to convert any arsenic present into chloride, when the arsenic chloride may be dissolved out by the oil treatment, as already described. —E. S.

Antimony oxides; Preventing the formation of crystallised oxides in the manufacture of — —. H. L. Herrenschmidt. Fr. Pat. 368,037, April 10, 1906.

BRICKWORK and masonry are replaced by sheet or cast-iron apparatus in the chambers and adjuncts used for collecting the antimony oxides, whereby quick cooling is insured, and the formation of crystallised oxides is prevented.—E. S.

Sulphates [Copper sulphate]; Manufacture of metallic ——. H. Abraham. Fr. Pat. 367,947, July 10, 1906.

THE invention is described with reference to obtaining copper sulphate from the sulphide, which latter is granulated and submitted to the action of a mixture of nitric and sulphuric acids with water. The nitrogen oxides evolved are led away to be converted, by air and water or steam, into nitric acid for use over again; and the nitrogen remaining after absorption of the oxygen of the air, may, if desired, be collected and utilised. The copper sulphate solution obtained, after separation from the sulphur set free, is set to crystallise, and the mother liquor is treated for the recovery of precious metals by immersing in it pairs of plates of copper and silver, in metallic contact, when it is stated the precious metals deposit chiefly on the silver plate.—E. S.

Hydrogen peroxide solutions; Stable ——. W. Heinrici. First Addition, dated July 4, 1906, to Fr. Pat. 356,880, Aug. 8, 1905 (this J., 1906, 19). Under Int. Conv., Aug. 28, 1905.

ACID solutions of hydrogen peroxide are rendered comparatively stable by the addition of a small proportion of an amide, imide, or acetyl derivative of an aromatic base, and derivatives of organic compounds of ammonia. The use of phenacetin for the stated purpose is specially indicated.—E. S.

GERMAN PATENTS.

Absorption tower for sulphuric anhydride. Dr. Schlamp vom Hofe und Co., Ges. für Einrichtung von Säurefabriken m.b.H. Ger. Pat. 166,599, June 22, 1904.

THE tower is constructed in sections (*a*, *b*, *c*, *d*, see figure) each of which is divided by a partition into a cooling chamber, *f*, and an absorption chamber, *g*, disposed as shown in the illustration. The cooling chambers have their bottoms shaped in the form of steps, *e*, and are provided with hollowed covers, *n*; in each chamber is a coil, *h*, leading from the cover, and opening above the adjacent absorption chamber. The plates forming the top and bottom of the absorption chambers are perforated. Above the upper section of the tower is a cover, *m*, having inlets, *k*, *l*, for the sulphuric acid used as absorbing agent; the walls of the cover are cut away in the form of teeth

Mineral exports of Mexico. For. Off. Ann. Ser., No. 3733. [T.R.]

THE following are statistics of the exports of minerals from Mexico during the years ended 30th June, 1905 and 1906:—

	1904–5.	1905–6.
	£	£
Gold bullion	2,595,365	2,772,131
„ in other forms	214,743	396,939
Silver bullion.....	5,301,402	6,604,310
„ in other forms	1,053,177	956,251
Antimony	78,623	103,908
Copper	2,980,342	2,865,590
Lead	550,467	496,781
Other minerals	32,413	95,054

Zinc industry of British Columbia. Bd. of Trade J., Nov. 29, 1906. [T.R.]

THE report of the Commission appointed to investigate the zinc resources of British Columbia states that zinc in large commercial quantities can be produced. The quantity immediately available in the Ainsworth and Slocan districts is estimated at 30,000 tons, of nominal zinc content of 50 per cent., equal to 12,000 tons of spelter. With correct methods of milling and treatment for the different classes of ores, a stable zinc industry should be established. Up to 1905 the production of zinc ore in British Columbia was 11,623 tons, which was chiefly exported to the United States. Since the establishment of smelting works at Frank (Alberta), Canada has entered the market for these ores.

Platinum in New Zealand. New Zealand Geological Survey, Bulletin No. 1, 1906, p. 50 and 96. [T.R.]

IN the Hokitika district of New Zealand, platinum has been found in quartz reefs intercalated in dark shaly *phyllite*. In the Taipo Gorge reef the platinum amounted to 1 dwt. per ton with 6 dwt. 13 gr. silver, gold being absent. In Harley's Creek reef, one sample gave 3 dwt. 8 grs., and another, 1 dwt. 2 grs. of platinum, gold being absent. As in the Urals, the platinum is here associated with magnesian eruptive rocks, and it is found that silver accompanies it in a fairly definite ratio of seven to one. Although the veins found up to the present time could scarcely be worked at a profit, it is suggested that others might be discovered if searched for within about a quarter of a mile of the Pounamu belt of eruptive rocks.

ENGLISH PATENTS.

Zinc; Treatment of sulphide ores containing ——. R. W. E. MacIvor, M. Fradd, and The Metals Extraction Corporation, London. Eng. Pat. 23,977, Nov. 21, 1905.

SEE Fr. Pat. 362,677 of 1906; this J., 1906, 765.—T. F. B.

Zinc; Method of realising the value of material containing —, and simultaneously profiting by the zinc and carbon constituents contained in the residue of zinc works. G. Stolzenwald, Valea Calugaresasca, Roumania. Eng. Pat. 18,134, Aug. 13, 1906.

THE residue from zinc distillation, containing both zinc and carbon, is mixed with fresh zinciferous material, and heated in a "long bedded, continuous acting furnace (Fortschaufelungsofen)," without further addition of combustibles or fluxes. Thus 100 parts of fresh material, containing 10 per cent. of zinc, may be mixed with 20 parts of a zinc residue containing 2 per cent. of zinc and 22 per cent. of carbon.—A. G. L.

Washing coal, coke, minerals, and the like; Machine for ——. G. H. Rayner and The Hardy Patent Pick Co. Eng. Pat. 1660, Jan. 22, 1906. Ill., page 1210.

FRENCH PATENTS.

Steel; Fibrous ——, and method of producing the same. E. F. Colborn. Fr. Pat. 367,999, July 12, 1906.

THE steel to be treated is heated to redness and then plunged into a solution consisting of 0·062 to 0·102 grm. of hippuric acid, 0·102 grm. of magnesium chloride, 1·555 grms. of chlorine, 12·441 grms. of sodium chloride, 12·441 grms. of ammonium chloride, 0·039 grm. of ammonia, and 4·543 litres of water. This solution is preferably contained in a closed vessel, which, after the steel has been introduced, is subjected to a pressure of from 3·5 to 7 kilos. per sq. cm. The quantity of the solution contained in the closed vessel should be such that the greater part is vaporised by the hot steel, the solution being stated to be more active in the gaseous state. The invention is especially applicable to inferior Bessemer steel, the strength of which is claimed to be greatly increased by the treatment.—A. G. L.

Metals in impalpable powder; Process of oxidising ——. C. L. C. Bertou. Fr. Pat. 361,798, Sept. 27, 1905.

METALS, such as tin, zinc, lead, or antimony, in impalpable powder, are submitted to the action of nascent oxygen, ozonised air or oxygen, or hydrogen peroxide in a vessel provided with heating and agitating means.—E. S.

Sulphur dioxide; Process for the utilisation of the —— produced in the smelting of antimony. G. R. M. Sweeting. Fr. Pat. 361,808, Oct. 3, 1905.

THE gases produced by the roasting of antimony ore to oxide are passed through a series of chambers containing water, the unabsorbed gases finally going to a chimney. The pipe leading the gases from the furnace into the first chamber is surrounded by a cold-water jacket, to prevent its attack by hot antimony oxide, some of which passes over with the gases. The water in the chambers must be kept well agitated to prevent stoppage of pipes by deposited antimony oxide. The solution finally obtained is filtered or decanted from the antimony oxide.—A. G. L.

Pyrophoric alloys for igniting and lighting purposes. C. Auer von Welsbach. First Addition, dated July 18, 1906, to Fr. Pat. 337,320, Oct. 31, 1903. Ill., page 1211.

Zinciferous material; Process for treating ——, and simultaneous recovery of the zinc and carbon contained in residues from the metallurgical treatment of zinc. G. Stolzenwald. Fr. Pat. 368,458, July 27, 1906. Under Int. Conv., Nov. 7, 1905.

SEE Eng. Pat. 18,134 of 1906; preceding these.—T. F. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 1157.)

(A.)—ELECTRO-CHEMISTRY.

Platinised electrodes for alkali chloride electrolysis; Application of grey ——. *I.* W. Geibel. Z. Elektrochem., 1906, **12**, 817—819.

IT has previously been demonstrated by Foerster (this J. 1902, 252) that platinum electrodes, upon which a fine black deposit of platinum has been made, enable the electrolytic production of hypochlorites and chlorates to be effected with a P.D. of from 0·5 to 0·6 volt below that necessary with bright polished platinum electrodes. For practical purposes this method is useless on account of the lack of durability of the black platinising. Grey platinising has up to the present proved unsuitable, but it has recently been found by Heraeus that a uniform and durable grey platinising can be carried out which the present author finds to give nearly as good results as Foerster obtained with platinum black, whilst at the same time the deposit seems to be lasting. Experimental results are given of a comparison of bright electrodes with black and grey platinised electrodes, showing that the difference in favour of the black platinising is only 0·04 to 0·1 volt, and that consequently the saving in energy over the bright electrodes is at least 80 per cent. of that attainable with black platinised electrodes. On the

other hand, the current yield is several per cent. better than with bright electrodes, and shows no marked difference from that obtained with the black platinised electrodes. —R. S. H.

Glass; Electrically-conducting ——. C. E. S. Phillips. VIII., page 1220.

ENGLISH PATENT.

Sterilisation [Electrolytic] of wood, cotton, rag, hair, fibres, or similar material for prevention of anthrax. I. Ickringill. Eng. Pat. 28,345. Nov. 14, 1905. V., page 1216.

UNITED STATES PATENT.

Electric Furnace. F. J. Tone, Niagara Falls, N.Y. U.S. Pat. 834,948, Nov. 6, 1906.

THIS furnace, which is of the resistance core type, is provided with side walls formed in movable sections which converge towards the base of the furnace. The base of the furnace is stationary, and is provided with a space for a cooling medium sufficient to prevent any substantial diversion of the current through the base. In this manner the current traverses the conducting material between the end electrodes, and heats the charge surrounding this conducting core. —R. S. H.

FRENCH PATENTS.

Furnace; Electric ——. B. Platschick. Fr. Pat. 361,831, Oct. 9, 1905.

SEE U.S. Pat. 826,962 of 1906; this J., 1906, 936.—T. F. B.

Glow-bodies, especially filaments of tungsten; Manufacture of metallic —— for electric lamps. Deutsche Gasglühlicht A.-G. (Auerges.). Fr. Pat. 367,386, June 8, 1906. II., page 1212.

Glow-bodies for incandescence electric lamps; Manufacture of metallic —— Deutsche Gasglühlicht A.-G. (Auerges.). Fr. Pat. 368,225, July 19, 1906. II., page 1212.

Bleaching wool; Process and apparatus for [electrically] ——. G. Pansa and A. Romberg. Fr. Pat. 368280, June 18, 1906. V., page 1217.

(B.)—ELECTRO-METALLURGY.

Iron; Polarisation capacity of —, and its relation to passivity. C. McC. Gordon and F. E. Clark. Z. Elektrochem., 1906, **12**, 769–772.

THE investigation was undertaken with a view of distinguishing whether the passivity of iron should be ascribed to the formation of an oxide film or to some allotropic change in the metal. A number of different electrolytes were employed, and short lengths of iron wire served as electrodes. The polarisation capacity was measured by comparison with a metallic condenser, and it was frequently found necessary to arrange a resistance in parallel with this condenser. This auxiliary circuit is found to be necessary in such cases as aluminium, where the capacity corresponds to a true electrostatic capacity, and is caused by the formation of a film of oxide. In all cases except in dilute nitric acid, in ferrous sulphate, and in ferric chloride solutions, a parallel shunted resistance is necessary with iron electrodes. The authors, therefore, conclude that the passivity of iron is caused by the formation of a film or layer of oxide upon the surface of the metal.—R. S. H.

ENGLISH PATENTS.

Gold; Apparatus for use in recovering —— from disintegrated ores. T. E. Beaumont, London. Eng. Pat. 25,319, Nov. 13, 1905.

THE ore pulp is supplied to the top of a wooden vat containing a 0·1 per cent. solution of potassium cyanide. In the centre of the lower part of the tub is supported a cylinder open at both ends, within which revolves a vertical propeller at an adjustable speed. The blades of this propeller are mounted so as to cause a continuous downward flow of the ore pulp through the cylinder; the pulp is then forced to pass between a wide horizontal flange attached to the cylinder and the surface of mercury contained in a cast-iron tray placed at the bottom of the vat. The amalgam can be removed from time to time by means of a stop-cock in this tray. The lighter particles of gangue and the fine gold not absorbed by the mercury pass upwards with the current of water outside the cylinder, and then pass between a series of concentric annular electrodes of amalgamated copper and iron, which are mounted on brackets in the upper part of the vat. The amalgamated copper electrodes, as well as the mercury at the bottom of the vat, are connected with the negative terminal of a generator giving a continuous current of about 6 volts, whilst the iron electrodes and the cylinder are connected to the positive terminal. Whenever the resistance in the vat becomes too great, as indicated by an ammeter in the circuit, additional cyanide solution is supplied so as to keep the strength of the solution approximately constant. An overflow pipe conducts excess of solution, and the lighter particles of the ore into a spitzkasten, from which the fine gold still unabsorbed, together with the finest particles of gangue, pass into a second vat similar to the first. If necessary, a third vat may receive the overflow from the second, but this should not be needed.—A. G. L.

Metallic compounds or ores; Electrolysis of —. E. A. Ashcroft, New York. Eng. Pat. 26,813, Dec. 22, 1905.

THE ore is electrolysed over a cathode which produces a fusible alloy with the metals, this alloy being conducted to a second cell, where it is used as an anode, and wherein the metals are precipitated fractionally at the cathode. The process may be applied to the elimination of iron from mixed ores, &c., of zinc or lead, the electrolysis being conducted at a high temperature to precipitate the iron before the lead, the corresponding solution of the iron before the lead in the second cell being effected by conducting the operation there at a lower temperature. —C. S.

Furnaces; Electric ——. H. Röchling and W. Rodenhauser, Völklinghen, Germany. Eng. Pat. 12,329, May 26, 1906.

SEE Fr. Pat. 366,440 of 1906; this J., 1906, 1054.—T. F. B.

FRENCH PATENTS.

Metallic flakes; [Electrolytic] Production of —. T. A. Edison. Fr. Pat. 367,863, July 7, 1906.

THE flakes of cobalt or of any alloy of cobalt or nickel required in the positive electrode of the Edison cell are produced by a modification of the method previously described (this J., 1906, 643). The present process consists in depositing electrolytically upon a suitable cathode a film of copper, then in another bath a film of cobalt, or cobalt-nickel alloy, subsequently a fresh layer of copper and so on, building up a composite deposit of alternate layers of copper and cobalt. The deposit is eventually removed *en bloc* from the cathode; it is cut up into strips of the size desired, and the copper is then removed. The treatment for the removal of the copper consists in acting upon the divided mass with a strong solution of cyanide, either directly or after the copper has been converted into some soluble salt.—R. S. H.

Metal pieces [rails]; Process of joining —— [by electrolysis]. C. F. Jacobs. Fr. Pat. 367,864, July 7, 1906.

THE metal pieces to be joined are surrounded by a mould, a molten flux or electrolyte is then poured into the cavity, and the ends of the metal heated by the passage of an electric current between them and through the flux. The flux may be composed of equal parts of borax, calcium fluoride, zinc chloride, and sodium chloride. When the ends of the metallic pieces are sufficiently heated, molten metal is poured into the mould. This metal may displace the flux by gravity, or, if desired, the flux can be run off before the admission of the metal.—R. S. H.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 1161.)

Cocoa nut oil; Alcoholysis of ——. A. Haller and Yousoufian. Compt. rend., 1906, **143**, 803—806.

The fatty matter from cocoa nut is submitted to the action of absolute methyl, ethyl, or other alcohol of this series, in the presence of a catalytic agent such as hydrochloric or phenylsulphonic acid, the proportion of catalyst present being 2 per cent. of the alcohol. The operation may be carried out in closed vessels at a temperature of 100° C., or in a flask attached to a reflux condenser, and the reaction even takes place at the ordinary temperature if the mixture be well shaken. The reaction is complete when the mass becomes homogeneous. In this way it was found possible to convert the constituent glycerides of the fat into their corresponding methyl esters, and to separate the latter from each other by means of fractional distillation. The total yield of esters agreed with that required by theory, and the distillation gave methyl caproate, caprylate, caprate, laurate, myristate, palmitate, stearate, and oleate. The corresponding glycerides are, therefore, present in cocoanut oil. Methyl butyrate was not found in the mixed esters. (See also this J., 1906, 1159.)—W. P. S.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(*Continued from page* 1162.)

(*A.*)—PIGMENTS, PAINTS.

English Patent.

Black oxide of iron; Manufacture of —— [*for use as a paint*]. J. Wetter, London. From C. F. Wülfing, Honningen-on-Rhine, Germany. Eng. Pat. 1050, Jan. 15, 1906.

Waste ferrous chloride liquors, after digestion with iron filings to neutralise free acid, are somewhat diluted, and two-thirds of the quantity of liquid ammonia necessary for saturation is added. Air is blown through the liquor, and after heating with steam, the remaining third of the ammonia required (or slightly more) is added. The mixture is again heated, the pan being closed, until about half an atmosphere pressure over the normal is attained. Finally, air is blown into the liquid until it is free from dissolved iron. The residual solution of ammonium chloride is concentrated to yield that salt as a by-product. The precipitated blue-black magnetic iron oxide, separated by filtration, is available as the basis for a paint for iron work. Waste ferrous sulphate liquors may be similarly treated.—E. S.

French Patent.

Lithopone, stable towards the action of light. W. Ostwald. Fr. Pat. 368,301, July 23, 1906.

The crude mixture of barium sulphate and zinc sulphide is roasted in a closed vessel, to prevent access of air, and means are devised for keeping out air in the subsequent slaking process. The roasting may also be performed continuously, in apparatus traversed by a current of gas free from oxygen.—C. S.

German Patent.

Silicate colours [pigments]; Process for the manufacture of ——. C. Barth. Ger. Pat. 167,934, June 19, 1904.

An aqueous solution of a suitable mixture of metallic salts is treated with a solution of an alkali- or alkaline-earth silicate, and the precipitated hydrous silicate is ground after being partially or completely dehydrated.
—A. S.

(*B.*)—RESINS, VARNISHES.

Copals; Study of some American ——. C. Coffignier. Bull. Soc. Chim., 1906, **35**, 1143—1150.

Employing the same methods as on former occasions (this J., 1902, 918; 1903, 808; 1905, 203) three American copals have been examined with the following results (the numbers placed against the various solvents are the percentages left undissolved by the boiling solvent):—

	Demerara	Columbia.	Brazil
Sp. gr. at 19° C.	1·047	1·054	1·053
Melting point	180° C.	above 300° C.	100° C.
Acid value	97·7	118·8	123·0
Saponification value	102·4	155·7	133·3
Solubility in —	per cent.	per cent.	per cent.
Ethyl alcohol	72·1	17·0	30·2
Methyl ,,	77·4	60·0	50·0
Amyl ,,	53·0	4·9	1·8
Ether	55·4	50·0	29·7
Chloroform	56·9	54·7	36·0
Benzene	70·9	60·8	40·5
Acetone	69·2	43·6	37·6
Oil of turpentine	92·5	68·7	48·2
Benzaldehyde	50·2	18·3	26·7
Aniline	73·9	2·2	8·3
Amyl acetate	37·1	6·0	3·4
Carbon tetrachloride	75·5	69·6	44·9

A peculiarity of Demerara copal is that it evolves a definite odour of valeric acid when it is freshly powdered. It is readily distinguished from Madagascar copal by the great difference between their solubilities in aniline.
—M. J. S.

French Patents.

Oil of turpentine and other products of wood; Extracting ——. M. McKenzie. Fr. Pat. 367,926, July 9, 1906.

The wood is subjected to the action of a heated bath of resin, rosin oil, other oils, hydrocarbons, or the like, in a still, the whole or part of the bath contents being then drawn off into a cooling vessel, and returned to act again on fresh wood. The bath is reheated before treating the next charge of wood. Means are provided for transferring the bath from one vessel to the other and through the heater; also for admitting steam or other suitable cooling agent to the cooling vessel.—C. S.

Wood; Treating —— *for the extraction of the oil of turpentine, with pitch and charcoal as by-products.* F. T. Snyder. Fr. Pat. 368,198, July 19, 1906. Under Int. Conv., Dec. 1, 1905, and May 31, 1906.

The wood is placed in an air-tight receptacle, which is inserted from below into a furnace, where it is heated, preferably by electricity. The oil of turpentine is drawn off from the bottom of the receptacle, which is kept cold, so that the pitch is not decomposed. When the distillation is finished, the receptacle is withdrawn and set aside in an upright position, to prevent access of air to the charcoal, whilst a fresh charged receptacle is inserted in the furnace.—C. S.

Driers for paint, varnish, and oil; Colourless ——. G. Guittet. Fr. Pat. 367,989, July 11, 1906.

Soluble metallic salts, such as lead acetate, manganese acetate, &c., are dissolved in alcohol, acetone, or amyl acetate, with or without the addition of a spirit varnish.
—C. S.

(C.)—INDIA-RUBBER, &c.

Rubbers from Uganda.—Bull. Imp. Inst., 1906, **4**, 202—204 and 226.

Samples of three different rubbers from the Uganda Protectorate have been examined, with the following results:—

(*a*) Rubber from *Funtumia elastica* (compare this J., 1906, 940).—The sample consisted of a rather dark coloured "biscuit," possessing good physical characteristics, and containing moisture, 1·7; caoutchouc, 84·6; resin, 6·4; albuminoid matter, 6·5; and ash, 0·8 per cent.

(*b*) Rubber from *Clitandra orientalis*.—The sample was in the form of a thin cake, dark brown in colour, and very strong and elastic. It contained moisture, 2·8; caoutchouc, 77·9; resin, 8·8; albuminoid matter, 9·4; and ash, 1·1 per cent.

(*c*) Rubber from *Landolphia Dawei*. Samples from three different localities were examined. All were in the form of thin sheet, pale in colour, and of good elasticity and strength. The samples contained moisture, 4·9; caoutchouc, 76·2; resin, 14·1; albuminoid matter, 2·0, and ash, 2·8 per cent. The amount of resin in rubber from *L. Dawei* probably varies with the age of the vine, a specimen previously examined having contained only 8 per cent. of resin in the dry material. The valuation in London of rubbers (*a*), (*b*) and (*c*), at a time when "fine hard Parà" was 5s. 5d. per lb., and Ceylon Parà "biscuits" 6s. 3d. per lb., was 5s. 6d. to 5s. 7d., 5s. 9d. and 5s. 9d. respectively. *Landolphia Dawei* is considered by Chevalier (Bull. Soc. Botanique de France, 1906, 17) to be one of the most promising of the *Landolphias* for cultivation in tropical Africa, at altitudes between 500 and 2000 m., or at lower elevations where there is a fairly uniform rainfall throughout the year. Monte Café, with altitude 700 m., average temperature 18° to 20° C., and annual rainfall 1·5 m., appears to be a particularly favourable spot. The yield of rubber is large, and the product of good quality, specimens being valued in Paris at 12 frs. per kilo (4s. 4d. per lb.), with fine Parà at 5s. 4d. per lb. (compare above, London valuation). E. W. L.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 1162.)

French Patents.

Tanning extracts; Decolorisation of —. L. Dufour. Fr. Pat. 367,917, July 9, 1906.

The extracts are treated with a mixture of hypophosphorous and phosphorous acids, or salts of these acids with sulphurous acid, or sulphites, bisulphites, and hypophosphites. Such mixtures have marked reducing and decolorising powers, which are increased by the addition of formalin and the application of a certain amount of heat. The quantities of the decoloriser and the temperature of the reaction depend upon the nature of the tanning material.—S. R. T.

Chrome tanning; Process of —. Lederfabrik Hirschberg vorm. H. Knoch und Co. Fr. Pat. 368,122, July 17, 1906.

According to the invention, a solution of the double pyrophosphate of sodium and chromium is decomposed by skin substance, and tans without the formation of acid or alkali. The double salt may be prepared beforehand, or produced during the tanning process from separate baths of sodium pyrophosphate and a chromium salt. Concentrations of 10° to 30° B. have given good results, but should be varied according to the quality of the skin and the kind of leather or rate of tanning desired. The method may be used in conjunction with other, mineral or vegetable tannages, and the addition of neutral salts or alkaline bodies, in solution or suspension, is beneficial.—S. R. T.

Ossein; Preparations and applications of —. A. Helbronner and E. A. Vallée. Fr. Pat. 361,796, Sept. 26, 1905.

Claim is made for solutions obtained by treating finely-divided ossein with cold alkaline solutions, and an intermediate body produced by arresting the action of the alkali when a transparent homogeneous colloidal mass has been formed. The latter is soluble in water, ammonia, alkalis, &c., and from these solutions, as also from those produced by the prolonged action of alkali, the ossein may be precipitated by neutral salts, acids, and certain organic liquids. The precipitated products are suitable for the preparation of textile fibres, dressings for various materials, or as a base for photographic emulsions.

—S. R. T.

German Patent.

Tanning hides and skins; Process for —. L. Ziegel. Ger. Pat. 165,238, July 31, 1902.

Skins or hides, prepared in the usual way, are treated with a solution containing aluminium phosphate, an alkali chloride, and a small quantity of sulphuric acid, and are finally worked in a soap solution. This process is stated to produce a leather similar to tawed leather; the product is very little affected by water, only a very small quantity of aluminium salt being extracted after long soaking.—T. F. B.

XV.—MANURES, &c.

(*Continued from page* 1163.)

French Patents.

Peat; Industrial treatment of — *to increase its content of nitrogen, in view of its application as a manure.* E. V. H. Bazin. First Addition, dated July 3, 1906, to Fr. Pat. 360,484, Dec. 14, 1905 (this J., 1906, 488).

A nitrière, or nitrate-producing ground, formed by the aid of blocks of peat, as described in the main patent, is supplied with effluent from sewage septic tanks. Such sewage, after remaining in the tank long enough to effect the necessary fermentation, may be siphoned on to the *nitrière*.—E. S.

Phosphates of iron and aluminium; Treatment of double — *in order to render the combined phosphoric acid soluble in ammonium citrate.* Pilon, Buffet, Durand-Gasselin et Cie. Fr. Pat. 368,521, July 30, 1906.

Native phosphates of iron and aluminium, either contained in upright retorts or directly exposed to the furnace flames, are slowly heated up to bright redness, the very slow and gradual character of the heating being an essential condition. The heating is sufficiently prolonged to expel both the combined and free water from the mineral. It is stated that the described treatment renders the insoluble phosphoric acid soluble in ammonium citrate.

—E. S.

XVI.—SUGAR, STARCH, GUM, &c.

(*Continued from page* 1165.)

Muscovado sugars; Fermentation changes occurring in —. F. Watts and H. A. Tempany. West Indian Bull., 1906, **7**, 226—236.

One of the authors has already called attention to the occurrence of fermentation changes in Muscovado sugars in the West Indies, whereby the polariscope test is subjected to alteration. It has been observed that the polarimetric reading varies, gas is evolved, and a vinous odour is produced, which, if the sample were enclosed in an air-tight vessel, after a time, becomes very strong indeed. To obtain an insight into the changes that occur during such fermentation, the authors have analysed, from time to time, a number of samples of fermenting sugar. It was found in all cases that the polarimetric reading first increased and then fell; at the same time, the amount of reducing sugar was diminished. If a fermenting sugar is kept for any long period of time, it was

found that it undergoes very marked deterioration in appearance. The preliminary rise of the polarisation reading appears to be due, in part, to the destruction of the lævulose preceding that of the dextrose. That the dextrose does undergo fermentation, was proved by inoculating a sterile solution of dextrose (containing traces of plant food) with fermenting sugar. The destruction of dextrose accounts for the first part of the fall of the polarimetric reading of the fermenting sugar; the subsequent fall is due to destruction of sucrose, as shown by determining, at intervals, the percentage of sucrose by Clerget's method. According to Greig-Smith and Steel, the decomposition of raw cane sugar is due to an organism, *Bacillus levaniformans*, the spores of which withstand a high temperature for a considerable time; this organism inverts the sugar and converts the product into a gum. The authors have found that fermenting muscovado sugar contains an organism, or organisms, which, when sown in sterile sucrose solutions containing traces of plant food, forms invert sugar and gum, and they are inclined to the opinion, that at certain stages of fermentation of fermenting sugar, dextro-rotatory substances are formed. Bacteriological examination of fermenting sugar showed that, in addition to some torula-like forms, numerous oval, free bacteria, 1—2 $\mu\mu$ long and 0·5 $\mu\mu$ broad, agreeing fairly well with the description of *B. levaniformans*, were present. On heating fermenting muscovado sugar at 100° C. for 1½ hours, it was found that the samples were completely sterilised; hence, unless the bacteria, present in the samples investigated, were free from spores, it appears that muscovado sugar does not contain a spore-bearing organism of a type very resistant to heat. L. E.

l-Iditol; Preparation and properties of crystallised ——. G. Bertrand and A. Lanzenberg. Bull. Soc. Chim., 1906, **35**, 1073—1079.

l-Iditol was prepared as follows:—Xylose, after solution in water, was converted by treatment with hydrocyanic acid, a little ammonia, and subsequent hydrolysis, into a mixture of *l*-gulonic and *l*-idonic acids; these were separated by alcoholic crystallisation. *l*-Gulonic lactone, which crystallised from the alcoholic solution, was converted, by treatment with pyridine, into *l*-idonic acid. By reduction, *l*-idonic acid furnished *l*-iditol which was purified, first by conversion into the tri-benzal derivative, and finally by crystallisation from alcohol. *l*-Iditol forms transparent, deliquescent, rhombic crystals (m. pt. 73·5° C.); in 10 per cent. aqueous solution the rotatory power is $[\alpha]_D^{20°} = +3·5°$. The hexacetate melts at 121·5°; $[\alpha]_D^{20°} = +25·33°$ in 5 per cent. chloroform solution.—L. E.

FRENCH PATENTS.

Sugar; Apparatus for extracting molasses from —— *by means of hot, compressed air.* A. Delettre. Fr. Pat. 368,007, April 17, 1906.

THE object of this apparatus is to extract molasses from sugar without recourse to a centrifugal machine. It includes a compressed-air chamber fitted with valves for admitting air, steam, and massecuite, and a valve for discharging sugar. A belt (consisting of an interlaced steel wire supporting belt, to which is fastened, by brass wire, a brass belt of similar construction), which passes over two drums, forms the bottom of the chamber. Massecuite is introduced into the chamber to a depth of 8—10 cm., the air valve is opened, the hot, compressed air drives the molasses through the belt into a hopper below, and the belt then moves forward a distance equal to the length of the chamber, the sugar being thereby discharged from the latter. The cycle of operations is then repeated.—L. E.

Saccharine juices; Economical process for purifying —— *by means of hydrofluosilicic acid, and the subsequent recovery of the acid.* H. Bertels. Fr. Pat. 368,421, June 20, 1906

SEE Eng. Pat. 17,554 of 1905; this J., 1906, 859.—T. F. B.

Sugar; Process for denaturing ——. P. Landouzy. Addition, dated June 29, 1906, to Fr. Pat. 364,072, March 13, 1906 (this J., 1906, 901).

THE inverted sugar to which tannin is added as denaturing agent, may be in the form either of massecuite or of syrup. —T. H. P.

Starch or alcohol; Process for extracting —— *from potatoes, together with a paste rich in nutritive matter.* C. Steffen. Fr. Pat. 368,002, July 12, 1906. XVIIIA., page 1230.

(*Continued from page* 1168.)

Brewing value of barley; Mealiness as a factor in estimating the ——. J. Brand. Z. ges. Brauw., 1906, **29**, 661—667.

THE conclusions at which the author arrives are briefly as follows:—An estimation of the original steeliness of a barley is no criterion of its value for malting. A knowledge of the degree of mealiness of a barley after steeping gives important indications as to the method of treatment to be adopted in the malt-house, but it gives no precise information with regard to the total nitrogen content of the barley. Corns which remain steely after steeping are always richer in protein than the mealy ones of the same kind, and are also those which yield steely malt and sinkers. Estimation of the steeliness after steeping is of the greatest value, as the irregularity of the modification increases with the proportion of corns exhibiting this residual steeliness. P. Lindner states that it is exceptional for a barley rich in protein to be mealy. This observation seems to have an anatomical basis, since barley corns rich in protein contain from four to six layers of aleurone cells and exhibit also an extraordinarily dense deposit of so-called histological protein; the aleurone layers of barleys poor in protein are only from two to four cells in thickness.—T. H. P.

Beer; Use of short-grown malt for the production of full-bodied ——. E. Rüffer. Woch. f. Brau., 1906, **23**, 671—672.

REFERRING to a recent lecture on the advantages of using a short-grown malt for the brewing of full-bodied beers, the author relates how this principle was being applied 50 years ago. At the brewery in question, the grist was made up with 50 per cent. of malt grown as long as possible, 25 per cent. of malt of a growth of only half the length of the first, and 25 per cent. of malt which had only just reached the sprouting stage. The long-grown malt was cured at a temperature of 81°—87·5° C., and the shorter malts were cured at 62·5°—69° C., the final curing temperature being maintained for three hours. The mash was mixed cold, and allowed to soak for an hour; heat was then applied by the direct introduction of steam into the mash tun, so that the temperature rose very slowly to 62·5° C. in about one hour. After a pause of three-quarters of an hour, the temperature was further raised to 77·5° C., and kept at that for one hour; then the wort was run off. The hops were mixed with the main wort in the copper, and allowed to steep whilst the grains were being sprayed with boiling water. When the last liquors were through, the wort was boiled for two hours. The worts were pitched at a gravity of 14° Balling, and fermentation was started at 5° C. for summer beers, and 7°—7·5° C. for winter beers. The summer beers were fermented for 14—16 days the winter beers for 8—10 days. Winter beers were browed with a larger proportion of long-grown malt and a smaller proportion of short-grown. The beers were cleared on shavings and were ready in 14 days. These beers were distinguished by their full body-flavour and excellent condition, and although highly attenuated, they required no "Kräusen" to prepare them for consumption.—J. F. B.

Maltase from malt; Hydrolytic action of ——. L. Marino and G. Fiorentino. Gaz. chim. ital., 1906, **36** [2], 395—427.

THE authors find that maltase of malt, free from emulsin and invertase, is capable, not only of decomposing maltose, but also of hydrolysing those natural and artificial glucosides which are decomposed by emulsin. The maltase was prepared by drying germinated barley at 25°—35° C., digesting it with three times its weight of water saturated with thymol, filtering, concentrating the filtrate at 35°—40° C. *in vacuo*, and precipitating the enzyme with 98 per cent. alcohol. It had the composition:—Carbon, 46·0; hydrogen, 7·2; nitrogen, 7·53; and ash, 1·5 per cent.; and contained traces of sulphur. The absence of emulsin in the maltase is shown by the fact that when the maltase was allowed to act upon amygdalin in concentrated solution, the hydrocyanic acid set free almost destroyed the activity of the enzyme, since on recovering the latter, it was found to be almost entirely without action on maltase or salicin. On adding a trace of emulsin to the recovered maltase, however, it became capable of almost completely hydrolysing salicin. Benzaldehyde and hydrocyanic acid have no influence on the activity of emulsin. Of the artificial glucosides, only the β-stereoisomerides of dextrose are decomposed by the maltase, and it is concluded, therefore, that the natural glucosides which are decomposed are also β-derivatives of dextrose. It appears evident from the results of these experiments that one and the same enzyme is capable of effecting hydrolysis in cases where it has hitherto been held that the action of two or more enzymes is required. The maltase from malt is capable of synthesising the same isomaltose from dextrose as is the maltase from beer yeast. (See also this J., 1906, 228.)—A. S.

Food products; Standards of purity for —— XVIII.A., see next column.

ENGLISH PATENTS.

Brewing; Process of — —. J. House, London. Eng. Pat. 18,351, Sept. 11, 1905.

A MIXTURE of malt and kilned raw grain is mashed, the temperature at the beginning being below 50° F., and rising to 150° F., the various enzymes being thereby enabled to exert their specific functions. The wort is then boiled, and cooled to 57° F., 10 per cent. of malt being mashed in at this temperature; the temperature is finally raised to 75° F. The wort is run off and boiled, that retained by the grain being expressed by air pressure. The grain residues are hydrolysed with acid, the wort being filtered by fluid pressure. The wort is cooled in a closed vessel, aerated by cold air, and fermented (preferably with a variety of types of true *S. cerevisæ*) in a closed vessel supplied with sterilised air, the beer being stored under carbon dioxide gas pressure. —L. E.

Brewing material, applicable also to other purposes, derived from starch and analogous farinaceous materials, and a new and useful process of making said brewing material. T. B. Wagner, Chicago. Eng. Pat. 2242, Jan. 29, 1906.

FARINACEOUS material is mixed with water, so as to form a "starch milk" (gravity about 22° B.), which is heated along with an acid for 40 minutes under a pressure of 20 lb., until reducing sugars begin to appear, their development being checked by neutralising the mass with alkali. The product is evaporated to dryness, preferably on a rotary hot cylinder. This product is amorphous, reduces Fehling solution, gives a perfect mash in presence of malt, is soluble in water at ordinary temperature, gives a violet or purple reaction with about 12 per cent. of iodine, and a reddish-brown with about 66 per cent. of that reagent.—C. S.

Beer; Vessels for use particularly in the sterilised manufacture of ——. L. Nathan, Zurich. Eng. Pat. 5619, March 8, 1906. Under Int. Conv., March 8, 1905.

THE vessel consists of an outer, cylindrical, iron shell, with an interior lining formed of a number of glass plates (preferably of milk-glass) concentric to the shell, and cemented to the latter with non-swelling cement, the edges of the plates being cemented together with acid-proof cement.—L. E.

Saccharine fruit juices [Wine making]; Process of desulphurising ——. E. A. Barbet, Paris. Eng. Pat. 13,217, June 7, 1906. Under Int. Conv., Oct. 27, 1905.

THE juice passes through regenerator tubes to the top of a column containing a series of plates, each provided with caps, acting as baffles, or with small holes, and an overflow. The descending juice is raised to ebullition (at a minimum temperature of 67° C.) by an ascending hot air current, which is introduced from a heater through a valve adjusted to give the requisite reduction of pressure. The air carries the sulphurous acid and other volatile substances to a condenser, the condensation products being run to waste. The juice passes from the bottom of the column to the above-mentioned heater, then through the regenerator and a cooler, to the fermenting vat. The plates of the column, and some other parts of the apparatus, are made of sandstone, the metallic parts with which the juice comes in contact being constructed of pure tin.—L. E.

FRENCH PATENT.

Starch or alcohol; Process for extracting —— *from potatoes, together with a paste rich in nutritive matter.* C. Steffen. Fr. Pat. 368,002, July 12, 1906. XVIII.A., page 1230.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 1169.)

(A.)—FOODS.

Food products; Standards of purity for — —. U.S. Dept. of Agric., Circular No. 19, 1906.

IN this circular the standards of purity recommended by a Committee of the Association of Official Agricultural Chemists, and endorsed by the U.S. Secretary of Agriculture, are given. Brief extracts from these standards are given below.

1. *Animal products.—Lard*, it is stated, contains, necessarily incorporated in the process of rendering, not more than 1 per cent. of substances other than fatty acids and fat. *Leaf lard* has an iodine value not greater than 60. *Milk* contains not less than 8·5 per cent. of non-fatty solids and not less than 3·25 per cent. of milk fat. *Cream* contains not less than 18 per cent. of milk fat. *Milk fat* or *butter fat* has a Reichert-Meissl value not less than 24 and a sp. gr. not less than 0·905 at 40°/40° C. *Butter* contains not less than 82·5 per cent. of milk fat. *Cheese* contains not less than 50 per cent. of milk fat referred to the water-free substance.

2. *Vegetable products.—Flour* contains not more than 13·5 per cent. of moisture, 1 per cent. of ash, and 0·5 per cent. of crude fibre, and not less than 1·25 per cent. of nitrogen. *Maize meal, corn meal*, or *Indian corn meal* contains not more than 14 per cent. of moisture and 1·6 per cent. of ash, and not less than 1·12 per cent. of nitrogen. *Oatmeal* contains not more than 12 per cent. of moisture, 1·5 per cent. of crude fibre, and 2·2 per cent. of ash, and not less than 2·24 per cent. of nitrogen. *Molasses* contains not more than 25 per cent. of water and 5 per cent. of ash. *Refiners' syrup* or *treacle* contains not more than 25 per cent. of water and 8 per cent. of ash. *Starch sugar, anhydrous*, contains not less than 95 per cent. of dextrose and not more than 0·8 per cent. of ash; 70 per cent. *sugar* or *brewers' sugar* contains not less than 70 per cent. of dextrose and not more than 0·8 per cent. of ash; and 80 *sugar, climax sugar*, or *acme sugar* contains not less than 80 per cent. of dextrose and not more than 1·5 per cent. of ash. *Glucose, mixing glucose*, or *confectioners' glucose* has a density at 100° F. (37·7° C.) of from 41° B. (not more than 21 per cent. of water) to 45° B. (not more than 14 per

cent. of water), and contains not more than 1 per cent. of ash on a basis of 41° B. *Honey* contains not more than 25 per cent. of water, 0·25 per cent. of ash, and 8 per cent. of sucrose. *Edible vegetable oils and fats:* The standards are given in the following table :—

Oil or fat.	Refractive index at 25° C.	Iodine value.
Olive oil	1·4660—1·4680	79—90
Cotton-seed oil	1·4700—1·4725	104—110
"Winter-yellow" cotton-seed oil	—	110—116
Peanut, earthnut, or arachis oil	1·4690—1·4707	87—100
Sesamé, gingili, or teel oil	1·4704—1·4717	103—112
Cocoa- or cacao-butter m pt 30°—35° C	1·4566—1·4598 (40° C.)	33—38
Cotton-seed oil stearine	—	85—100

Chocolate, plain chocolate, bitter chocolate, chocolate liquor, or *bitter chocolate coating* contains not more than 3 per cent. of ash insoluble in water, 3·50 per cent. of crude fibre, and 9 per cent. of starch, and not less than 45 per cent. of cocoa fat.

Beverages.—*Wine* contains 7—16 per cent. of alcohol by volume, and in 100 c.c. at 20° C. not more than 0·1 grm. of sodium chloride and 0·2 grm. of potassium sulphate, and not more than 0·14 grm. for red wine, or 0·12 grm. for white wine of volatile acids, calculated as acetic acid. *Dry wine* contains in 100 c.c. at 20° C. less than 1 grm. of sugars, and for red wine not less than 0·16 grm. of grape ash and 1·6 grms. of sugar-free grape solids, and for white wine not less than 0·13 grm. of grape ash and 1·4 grms. of sugar-free grape solids. For vinegars the minimum standards are as follow :—

Kind of vinegar.	100 c.c. at 20°C contain :—			Water-soluble ash from 100 c.c.	
	Acetic acid.	Solids	Ash	Contains phosphoric acid (P_2O_5)	Requires for neutralisation.
	grms	grms not less than	grm	mgrms.	c.c of $N/10$ acid.
*Cider, apple, (lævo-rotatory)	4	1·6	0·25	10	30
Wine, grape	,,	1·0	0·13	—	—
Malt, (dextro-rotatory)	,,	2·0	0·2	9	4
Sugar	,,	—	—	—	—
Glucose	,,	—	—	—	—
Spirit, distilled, grain	,,	—	—	—	—

*Solids contain not more than 50 per cent. of reducing sugars.

Table salt, dairy salt contains not more than 1·4 per cent. of calcium sulphate, 0·5 per cent. of calcium and magnesium chlorides, and 0·1 per cent. of insoluble matter, referred to water-free substance. (See also this J., 1906, 651.) A. S.

Cocoa nut oil; Alcoholysis of ——. A. Haller and Youssoufian. XII., page 1226.

Vicianin, a cyanogenetic glucoside contained in vetches. G. Bertrand. XX., page 1231.

English Patent.

[*Milk*] *Separators; Centrifugal* ——. Aktiebolaget Separator, Stockholm. Eng. Pat. 21,424, Sept. 27, 1906. Under Int. Conv., Oct. 23, 1905.

The claim is for a feeding device for milk separators, which fits into the neck of the apparatus, and is divided vertically into several channels. The milk is fed down some of these into the space opposite the distributing holes in the discs, and the separated cream rises up the other channels to the outlet.—W. H. C.

French Patent.

Starch or alcohol; Process for extracting —— from potatoes, together with a paste rich in nutritive matter. C. Steffen. Fr. Pat. 368,002, July 12, 1906.

Potato slices are fed continuously into a mixer provided with a transport arrangement, together with potato juice in sufficient quantity to extract the starch, the juice being then led into a separator, in which it is more or less freed from starch, and afterwards returned to the mixer to act on fresh potato slices. The residue of the potatoes is submitted to pressure in presses similar to those employed for pressing beet slices, the juice thus obtained being added to the juice with which the potato slices are treated. The excess of juice, either as it is or after removal of the albumin by precipitation and filtration, is converted by evaporation into syrup of convenient concentration, which is mixed with the pressed potatoes, either before or after these are dried; the mixture can be employed directly for agricultural purposes. This process can be used in potato-spirit distilleries, so that in addition to the alcohol, a dry material suitable for fodder, is obtained.—T. H. P.

(*B.*)—SANITATION; WATER PURIFICATION.

Refuse destructor at Burslem Electricity Works. Elect. Engin., 1906, **38**, 294—296. Science Abstracts, 1906, **9B**, 504—505.

The destructor is of the "Heenan" type, with three cells, which are fed from the front. The normal capacity of these cells is 25 tons of refuse per 18 hours. The combustion chamber is arranged at right angles to the cells, and from it the gases pass through a Babcock and Wilcox boiler capable of evaporating 6,000 lb. of water per hour at a pressure of 200 lb. per sq. in. The gases leaving the boiler are used to heat the air used for forced draught. The air required for this purpose is taken from the clinkering floor, which tends to keep the building well ventilated. The forced draught is obtained by means of an electrically-driven centrifugal fan. The following are the figures from an official test of this destructor carried out on Nov. 14, 1905: Duration of test, 7½ hours; total fire-grate area, 75 sq. ft.; heating surface of boiler, 1,966 sq. ft.; class of refuse dealt with during test, trade and domestic. Total refuse burnt during test, 26,572 lb.; average rate of burning per hour per sq. ft. of grate area, 48·8 lb.; total water evaporated during test (actual), 49,990 lb.; evaporation per lb. of refuse (actual), 1·87 lb.; equivalent per lb. of refuse from and at 212° F., 2·16 lb.; temperature of feed-water entering tank, 45° F.; average temperature of combustion chamber during test, 2,032° F.; percentage of clinker (by weight), 26·5.

Refuse destructor at Brünn. S. Bourdot. Elekt. Runds., 1906, **23**, 331—333, 343—346, 366—369, and 380—381. Science Abstracts, 1906, **9B**, 505.

Trials at Cologne, carried out in March, 1904, with the destructor of A. Custodis and F. A. Herbertz, were entirely successful. The plant consists of seven destructor cells, with a capacity of 52,500 kilos. of refuse per 24 hours. The refuse is collected in special wagons, which are provided with discharging doors in the bottom. A transporter system carries the refuse to the storage bin, which is of 126 cb. m. capacity, and has openings opposite to each of the cells. The refuse is burnt upon the grate with an air pressure of 350 mm. water (14 in.), at the rate of 313 kilos. per sq. m. of grate surface per hour. Two chambers lined with refractory material are built behind the cells, and complete the combustion of the lighter particles of refuse carried away with the draught. A Babcock and Wilcox Water-tube boiler is installed next to the destructor cells, having 108 tubes and 220 sq. m. of heating surface. This boiler can be heated either by the destructor cell gases or independently by coal. An economiser and a chimney 40 m. in height complete the plant. The steam generated is used or driving a 300-h.p. turbine and dynamo, which

supply the power required for running the destructor plant, A 25-h.p. motor drives the fans which provide the blast for the destructor cells. These deliver 105 cb. m. and 130 cb. m. of air per minute respectively. The clinker from the cells is ground in a special mill and sold. A test run with the plant gave an evaporative effect of 1·13 kilos. of water for 1 kilo. of refuse, with 8·8 per cent. of carbon dioxide in the exit gases, and an exit temperature from the boiler plant of 279° C. The total material charged during this run was 26,898 kilos., at the rate of 2,782 kilos. per hour, and the weight of clinker removed was 12,038 kilos., with an additional 3,473 kilos. of flue dust and ashes. Extended trials with the destructor plant during January, February, and March, 1906, show a mean evaporative effect of 1·05 kilos. of water per 1 kilo. of refuse.

ENGLISH PATENT.

Water for boiler feeding, laundry, and other work; Apparatus for softening, heating, and purifying — —. A. B. C. and J. A. Danks, Netherton, Staffs. Eng. Pat. 20,277, Oct. 7, 1905.

THE heated water is run into a small tank, fitted with a float operating the valve of the reagent tank, so as to admit a predetermined quantity of the reagent into the water tank. The mixture is discharged into a mixing chamber, fitted with sloping shelves; and from the bottom of this chamber it ascends into an intermediate settling chamber, in which it flows through a number of narrow orifices and over inclined shelves, to induce the deposition of the precipitated impurities. From the top of this chamber, the water is drawn through a pipe into the bottom of a second settling chamber, from the top of which again it flows to a bottom filtration chamber, and thence to the soft-water tank. Means are provided for heating the water as it enters the apparatus, and keeping it at a regular temperature during its passage through the same, either by direct, live steam or by exhaust steam in pipes.—C. S.

XIX.—PAPER, PASTEBOARD, &c.

(*Continued from page* 1170.)

ENGLISH PATENT.

Sizing composition for use in the manufacture of paper, and process of producing same. Soc. Anon. Mirabet, Barcelona, Spain. Eng. Pat. 10,486, May 4, 1906. Under Int. Conv., May 5, 1905.

SEE Fr. Pat. 355,852 of 1905; this J., 1905, 1252.—T. F. B.

FRENCH PATENTS.

Celluloid; Non-inflammable —— containing no camphor. L. Béthisy, L. Fouchard, and E. Vignes. Fr. Pat. 368,004, July 12, 1906.

BLEACHED tetranitrocellulose, containing 40 to 45 per cent. of water, is incorporated with about 5 per cent. of a liquid hydrocarbon, preferably essential oil of aspic, and also with the necessary colouring matter. The mixture is then treated with a mixture of alcohol, ether, acetone, and amyl acetate for about six hours, when it is rolled into sheets between rollers heated to 60° C. A mixture of ether, boric acid, calcium ethylate (75 per cent.), and ammonium thiocyanate is then run on to the sheets, and the rolling is continued. The product is submitted, in a closed vessel, to a pressure of 150 atmospheres, and is heated by steam at 90° C., for five to six hours, after which it is cooled by means of water while still under great pressure, and dried.—T. F. B.

Silk, artificial; Production of —— from collodions made with acetone or ethyl acetate. J. A. E. H. Bouillier. Fr. Pat. 368,190, July 19, 1906. V., page 1217.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 1173.)

Quinine formates. H. Lacroix. J. Pharm. Chim., 1906, **24**, 493—494.

Neutral quinine formate commences to lose its acid at 50° C., and is completely dissociated at 95° C., the residue being alkaloidal quinine and not a basic formate. The salt also dissociates on solution in cold water into free formic acid and basic quinine formate. *Basic quinine formate* or "quinoform" is stable, even in boiling aqueous solution; it loses part of its acid near the melting point, which is 109° C., and not 132° C. as previously stated (this J., 1905, 902). Its rotation is now stated as $[\alpha]_D^{20°} = -144·2°$, and not $[\alpha]_D = -141·1°$.—J. O. B.

Vicianin, a cyanogenetic glucoside contained in vetches. G. Bertrand. Compt. rend., 1906, **143**, 832—834.

THIS glucoside is contained in a member of the vetch family, *Vicia angustifolia*, widely distributed in France. It crystallises in the form of colourless needles, and is very soluble in hot water, but only slightly so in cold water; whilst being soluble to a small extent in alcohol, it is insoluble in petroleum spirit, benzene, carbon bisulphide, and chloroform. It melts at 160° C., and its saturated aqueous solution at 16° C. has the rotatory power −20°.7. The glucoside contains 3·2 per cent. of nitrogen, which, on treatment with emulsin, is liberated entirely as hydrocyanic acid. The seeds of the plant yield about 0·075 per cent. of hydrocyanic acid, which fact renders their presence in fodder dangerous to animals.—W. P. S.

Hydrazine salts; Iodometric determination of ——, and its application in volumetric analysis. E. Rimini. XXIII., page 1233.

ENGLISH PATENTS.

Ergot; New or improved substance from ——. G. B. Ellis, London. From E. Merck, Darmstadt, Germany. Eng. Pat. 239, Jan. 3, 1906.

CLAIM is made for the manufacture of a crystalline substance from ergot, by treating an aqueous extract of ergot with barium hydroxide, removing the excess of baryta from the filtrate, filtering, and evaporating to a syrupy residue. The residue is crystallised from alcohol. Or, the aqueous extract may be evaporated, and the residue extracted with boiling dilute alcohol. Claim is made for the substance so obtained, which has the following properties. It is a nitrogenous substance easily soluble in water, but insoluble in absolute alcohol, ether, and light petroleum. It crystallises from 75 per cent. alcohol in colourless needles. When carefully heated it sublimes. (See this J., 1906, 906.)—F. SHDN.

Catechine; Process of converting —— into catechu-tannic acid. W. Osborne and H. Schupp, Munich, Germany. Eng. Pat. 18,004, Aug. 10, 1906. Under Int. Conv., Aug. 14, 1905.

CATECHIN [catechuic acid] can be converted into catechu tannic acid by heating pure catechin, or catechu containing catechin, in a melted resinous mass of colophony, mastic, Burgundy pitch or the like, with or without the addition of stearine, paraffin, wax, guttapercha or the like. The advantage of this method is that the proper temperature for the reaction can be easily maintained, and the acid is protected from oxidation.—F. SHDN.

Alcohols, and especially ethyl alcohol; Depriving —— of water. Elektrochem. Werke, G.m.b.H., Bitterfeld, Germany. Eng. Pat. 21,567, Sept. 29, 1906. Under Int. Conv., Sept. 29, 1905.

THE alcohol is heated one or more times in presence of granulated calcium, and then distilled.—C. S.

UNITED STATES PATENT.

Carbon tetrachloride; Manufacture of ——. J. M. Matthews, Philadelphia, Assignor to F. Darlington, Great Barrington, Mass. U.S. Pat. 835,307, Nov. 6, 1906.

A MIXTURE of an alkaline-earth chloride (preferably calcium chloride) and carbon in suitable proportions is heated to a high temperature, *e.g.*, by an electric current, in presence of a non-oxidising gas, whereby a mixture of a carbide and chlorine compounds of carbon is produced; the carbon chlorides are subsequently treated with chlorine to convert them into carbon tetrachloride.
—T. F. B.

FRENCH PATENTS.

Dialkylbarbituric acids; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 367,872, July 7, 1906. Under Int. Conv., Dec. 7, 1905.

DIURETHANES of dialkylmalonic acids are converted into dialkybarbituric acids by heating, either alone, or in presence of urea, diphenyl carbonate, &c. The diurethanes, obtained by the condensation of 2 mols. of urethane with 1 mol. of dialkylmalonic acid, may be heated for five hours, at 200° to 210° C., or a mixture of 10 parts of the diurethane with 7 parts of urea may be similarly heated. (Compare Eng. Pats. 14,161 and 23,718 of 1905; this J., 1905, 1188, and 1906, 1002.)—T. F. B.

Salicylic acid; Process for preparing new derivatives of ——, *and new intermediate products therefor.* Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 368,133, July 17, 1906. Under Int. Conv., March 22, 1906.

BY the action of phosphorus pentahalides on anhydromethylene-citric acid $(HOOC.CH_2)_2C<\begin{matrix}O\\CO.O\end{matrix}>CH_2$, the corresponding acid halides are obtained; these may be combined with salicylic acid, forming anhydromethylene-citrylsalicylic acid.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 1174.)

Light; A new action of ——, *and its photographic application.* F. Alefeld. Chem.-Zeit., 1906, **30**, 1087—1090, 1127—1128.

BY coating sheets of material, capable of resisting a dull red heat, with thin, amorphous layers of certain solutions capable of yielding coloured residues, drying, exposing to light behind a negative, and finally heating strongly, positives were obtained, in which the shadows were represented by the residue of metal, the substance having apparently migrated towards the more transparent parts of the negative under the influence of light; no chemical action of any kind was detected. The most suitable substances are the resinates and thioresinates of the heavy metals, such as are used in potteries in the production of "lustre ware"; all the heavy metal compounds tried gave similar results, as also did an aqueous solution of ferric chloride, and certain solutions of organic substances, *e.g.*, colophony in toluol, Venetian turpentine, and certain other essential oils, natural asphaltum dissolved in chloroform, benzene, &c., collodion, and a solution of an extract of yeast. Glass, porcelain, and metal are most suitable as supports. The process possesses the disadvantage that it is not found possible to obtain pure whites, owing to part of the metal, &c., always remaining beneath the dense portion of the negatives. The time required for full exposure is 15 to 30 minutes, but a few seconds only suffices to produce some effect upon plates dried for a short time at the ordinary temperature. The duration and temperature of the drying of plates have a very great effect on their sensitiveness, high temperatures especially tending to reduce the rapidity of the action.—T. F. B.

Photographic plates or papers; Hardening the gelatin film of —— in the fixing bath. A. and L. Lumière and A. Seyewetz. Phot. Wochenbl., 1906, **32**, 41. Chem.-Zeit., 1906, **30**, Rep., 408.

FORMALDEHYDE in its different forms, and aluminium and chromium salts cannot be used in the fixing solution for various reasons; it is, however, found that aluminium or chromium salts in conjunction with sodium bisulphite will satisfactorily harden the gelatin film of photographic plates or papers when added to the thiosulphate solution. Five grms. of chrome alum, or 15 grms. of potash alum and 10 to 15 c.c. of "commercial" bisulphite solution are added to 1 litre of 15 per cent. sodium thiosulphate solution; no advantage is obtained by further addition of bisulphite or alum. After the chrome alum treatment, the gelatin will withstand a temperature of 100° C., but the film treated with potash alum cannot be heated above 75° C. with safety. The above treatment does not prejudice subsequent intensification, reduction, or colouring of the film.—T. F. B.

Diffraction gratings; Intensification of glass ——. R. W. Wood. Phil. Mag., 1906, **12**, 585—588.

IMPERFECTLY ruled glass diffraction gratings can be much improved by immersion for one or two minutes in 1 per cent. hydrofluoric acid solution, the back of the glass being covered with paraffin wax to prevent the development of latent scratches.—T. F. B.

ENGLISH PATENT.

Photographic and other prints; Production of ——. J. Rieder, Munchen, Germany. Eng. Pat. 23,109, Nov. 10, 1905.

SEE Fr. Pat. 359,218 of 1905; this J., 1906, 393.—T. F. B.

FRENCH PATENT.

Ossein; Preparations and applications of ——. A. Helbronner and E. A. Vallée. Fr. Pat. 361,796, Sept. 26, 1905. XIV., page 1227.

XXII.—EXPLOSIVES, MATCHES, &c.

(*Continued from page* 1175.)

ENGLISH PATENTS.

Explosives. W. Venier, Vienna. Eng. Pat. 6705, March 20, 1906.

SEE Fr. Pat. 364,461 of 1906; this J., 1906, 911.—T. F. B.

Explosives. C. G. Luis and J. C. Williamson, London. Eng. Pat. 20,889, Sept. 20, 1906.

GREEN-OIL or red-oil, an oil purified by fractional distillation from the tar obtained from certain varieties of "brown coal," is mixed with an oxidising agent such as ammonium nitrate or ammonium perchlorate. This explosive, it is claimed, is very powerful, does not freeze, and is therefore useful as a blasting explosive. A mixture of 12 per cent. of green-oil, 72 per cent. of ammonium perchlorate, and 16 per cent. of trinitrotoluene gave good results on trial.—B. J. S.

UNITED STATES PATENT.

Powder stripe; Machine for cutting ——. J. T. Thompson, Assignor to the E. I. Du Pont De Nemours Powder Co., Wilmington, Del. U.S. Pat. 827,674, July 31, 1906.

SEE Fr. Pat. 367,945 of 1906; following these.—T. F. B.

FRENCH PATENT.

Powder; Machine for cutting bands of ——. The E. I. Du Pont De Nemours Powder Co. Fr. Pat. 367,945, July 10, 1906.

THE machine comprises a series of rollers, arranged in groups, with different working apertures; a disc provided with corresponding orifices; a cutting disc with blades, the rollers and perforated disc being relatively adjustable,

so that their orifices can be set opposite each other, a variable speed gear enabling the rollers to be run at speeds corresponding with the orifice employed; a double shoot for carrying off the cut fragments of powder and fitted with a valve closing each shoot alternately; also a mirror arranged behind the cutters and tilted at an angle enabling the operator to see the cut fragments.

—C. S.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 1176.)

INORGANIC—QUANTITATIVE.

Copper; Volumetric determination of —— with potassium iodide. H. Cantoni and M. Rosenstein. Bull Soc. Chim., 1906, **35**, 1069—1073.

The authors show, by several series of experiments, that the accuracy of the iodine-thiosulphate method for determining copper, is dependent on certain conditions under which the analysis may be performed. The titration is considerably affected by the degree of dilution, by the presence of free acetic acid, and, to a small extent by the presence of sulphates of potassium, sodium, ammonium, zinc, and manganese. In working with copper acetate and the alkali acetates, the differences which result are but trifling and may be neglected. The standardisation of the thiosulphate solution should be executed under definite conditions, and these same conditions should be subsequently adhered to as closely as possible in the analyses.

—L. E.

Zinc; Ferrocyanide method for the determination of ——. W. H. Seamon. Mining World, 1906, 544—545.

The author has made a large number of experiments to determine the influence of varying conditions on the ferrocyanide method for zinc. He shows that Low is right in giving warning against the use of granulated lead for the removal of copper, as adopted by the Committee on Uniformity of Analysis of the Society of Western Chemists and Metallurgists (Pennsylvania). Some of the lead used passes into solution and then consumes ferrocyanide, leading to high results. Instead of lead, aluminium should be used to remove the copper, the presence of aluminium in the solution not affecting the results.—A. G. L.

Beryllium [Glucinum]; Separation of ——from aluminium. C. Friedheim. Ber., 1906, **39**, 3868—3869.

Glassmann's proposal (this J., 1906, 1121), to effect the separation of beryllium from aluminium by means of sodium thiosulphate, is not new. Chancel in 1858 first proposed the use of thiosulphate to precipitate alumina, and Joy, in 1863, applied the reaction, unsuccessfully, to separate aluminium from beryllium. Zimmermann in 1888, at the author's suggestion, revised Joy's work, and found that good results were obtainable provided the two metals were present in about equal proportions. Glassmann's results were obtained on mixtures in about these proportions. The precipitate is not simply a mixture of alumina and sulphur, but contains in addition basic sulphate and sulphite. (See also this J., 1906, 1147.)

—J. T. D.

Nitrates; Determination of —— F. S. Sinnatt. Chem. Soc. Proc., 1906, **22**, 255.

Knecht and Hibbert's method for the estimation of picric acid (this J., 1903, 762) may be applied to the estimation of nitrates. The process depends on the conversion of the nitrate into picric acid by means of phenolsulphonic acid, the picric acid being subsequently estimated by titanium trichloride. Ten c.c. of the solution of potassium nitrate containing 0·1 per cent. of potassium salt were evaporated to dryness in a steam oven, 5 c.c. of a solution of phenolsulphonic acid added, and the heating continued for half an hour. The whole was then washed into a flask, and, after adding hydrochloric acid, titrated with titanium trichloride. Three titrations carried out in the above manner required for 0·01 grm. of potassium nitrate, 20·14, 20·47, and 20·2 c.c. of titanium trichloride (1 c.c. = 0·0004860 grm. of potassium nitrate), corresponding to 0·009788, 0·009948, and 0·009817 grm. of potassium nitrate respectively. The error is not so great as when the colorimetric method is used.

Hydrazine salts; Iodometric determination of ——, and its application in volumetric analysis. E. Rimini. Org. Quant., see next abstract.

ORGANIC—QUANTITATIVE.

Hydrazine salts; Iodometric determination of ——, and its application in volumetric analysis. E. Rimini. Atti R. Accad. dei Lincei, Roma, 1906, **15** [2], 320—325. Chem. Centr., 1906, **2**, 1662—1663.

The author has simplified his method for the determination of hydrazine (this J., 1899, 1059) by working in alkaline solution, and thus avoiding the formation of iodine from the interaction of iodide and iodate. With hydrazine sulphate, the reaction proceeds according to the equation:

$$3(N_2H_4,H_2SO_4)+2KIO_3+6KOH = 3N_2+2KI+3K_2SO_4+12H_2O.$$

The evolution of nitrogen is complete and rapid.

In the determination of formaldehyde by Riegler's method (this J., 1901, 510) the excess of hydrazine should be titrated with iodate in alkaline solution. If iodide be present, the solution must be acidified in order to decompose the excess of iodate, and titrated back with sodium thiosulphate, 2 mols. of iodate being equivalent to 3 mols. of hydrazine.

The following method is recommended in place of that of Ebler (this J., 1905, 1257) for the determination of mercury. A concentrated solution of hydrazine sulphate is made neutral to methyl orange, and a measured excess of $N/2$ sodium hydroxide solution and the mercury salt under examination, are added. After heating, the whole is made up to a definite volume, and in an aliquot part of the clear solution, the remaining alkali is determined by titration with $N/2$ acid. The reaction is expressed by the equation:

$$N_2H_4,H_2SO_4+2HgCl_2+5NaOH = 4NaCl+NaHSO_4+2Hg+N_2+5H_2O.$$

Pannain's method (this J., 1904, 882) for the determination of persulphates is stated to give too high results. The following method is proposed:—A solution of the persulphate, neutral to methyl orange, is treated with a solution of hydrazine sulphate neutralised with potassium hydroxide, then shaken with a known quantity of a standardised solution of potassium hydroxide, and after five minutes, the excess of alkali titrated back.

$$2K_2S_2O_8+N_2H_4,KHSO_4+5KOH = N_2+5K_2SO_4+5H_2O.$$

—A. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 1177.)

Sulphur; Note on the sublimation of —— at ordinary temperatures. R. J. Moss. Scient. Proc. Roy. Dublin Soc., 1906, **11**, 105—106.

Twenty-five years ago the author placed some fragments of sulphur in a glass tube, which was then exhausted, sealed, and placed in a drawer. After nearly twenty years had elapsed a very minute crystal was observed on the wall of the tube, which was then hung on a wall and examined at intervals. At the present time the whole of the side of the tube furthest from the wall is studded with minute crystals, which are apparently rhombic, but show greater complexity than crystals deposited from solutions of sulphur.—A. S.

Mineral springs; Fractionation of the rare gas from the waters of ——. Proportions of helium. C. Moureu and R. Biquard. Compt. rend., 1906, **143**, 795.

The authors have fractionated the residue of argon, helium, neon, &c., remaining after removing the other gases from the gas obtained from various mineral springs, by means of the absorptive action of charcoal at a low temperature. The table below gives the amounts, expressed

as percentages of the total volume of gas obtained, of the rare gases as a whole, and of the helium present :

Spring.	Total rare gases.	Helium.

—J. T. D.

Carbon and hydrogen ; Direct union of —— at high temperatures. J. N. Pring and R. S. Hutton. Chem. Soc. Trans., 1906, **89**, 1591—1601.

In the authors' experiments, which were carried out at temperatures ranging from 1000° C. up to about 2800° C., a carbon rod mounted at its ends in water-cooled brass tubes was heated electrically in an atmosphere of hydrogen, in a glass tube, or a water-jacketed metal bell-jar. The carbon was previously purified by heating in a vacuum, and in some cases, also, by heating in chlorine. Minute quantities of acetylene are produced at 1700° C., but below 1800° C. the percentage is scarcely measureable by ordinary gas-analysis methods. The percentages of acetylene in the gas after the experiments are given in a table, from which the following figures are taken :—At 1870° C. in 9 mins., 0·42 per cent. ; 1900° (17 minutes), 0·26 ; 2000° (20 minutes, 0·55 ; 2000° (16 minutes, carbon specially purified with chlorine), 0·88 ; 2400° (4 minutes), 3·26 ; 2500° (4 minutes), 4·20 ; 2700° (2 minutes), 2·75—3·05 ; and 2800° C. (1 minute, equilibrium probably not obtained), 2·73 per cent. In all cases a small amount of methane was produced, but this was less when the carbon was specially purified with chlorine, and in general the greater the precautions were to improve the quality of the carbon, the less methane was formed. This tends to support Berthelot's view that with pure materials hydrocarbons are not formed at 1200° C. as stated by Bone and Jerdan (this J., 1901, 696).—A. S.

Solutions ; Contributions to the theory of ——. I. The nature of the molecular arrangement in aqueous mixtures of the lower alcohols and acids of the paraffin series. II. Molecular complexity in the liquid state. III. Theory of the intermiscibility of liquids. J. Holmes. Chem. Soc. Trans., 1906, **89**, 1774—1786.

1. The differences in volume which occur on mixing the lower alcohols (methyl, ethyl, and normal propyl) and acids (formic, acetic, propionic, and normal butyric) of the paraffin series with water, were calculated from available data, and it was found that in all cases the greatest difference between the percentage of alcohol or acid by volume in the mixture and the theoretical percentage, assuming that no contraction took place on mixing, occurred approximately at the point representing an admixture of equal molecular volumes, referred to the gaseous state. The results are discussed on the assumption that the free path of a liquid molecule can be represented by a spherical surface and it is argued that they show the molecular complexity of water is approximately the same as that of each of the alcohols and acids named, and that the existence of hydrates must be excluded from the theory of solutions. II. Working on somewhat similar lines to those mentioned above, the author concludes that if the degree of aggregation of water and the alcohols be taken as 1, that of ethyl ether and of pyridine is also 1, that of chloroform and of benzene is 2, and that of carbon bisulphide is 3. III. From the relative molecular volumes of a number of organic liquids compared with that of water at the same temperature as unity, and from the degree of aggregation of the different compounds in the liquid state, the true molecular volumes were deduced, and it was found that, with one exception, a decrease of solubility occurs with increase in molecular volume. Also, liquids standing near to each other in the series (arranged in the order of the true molecular volumes), and possessing molecular volumes within certain dimensions are mutually miscible. —A. S.

Dextrose ; Decomposition of —— with ammoniacal zinc hydroxide in the presence of acetaldehyde. A. Windaus. Ber., 1906, **39**, 3886—3891.

It has been previously shown (see this J., 1905, 515) that dextrose, on treatment with ammonia and zinc hydroxide or caustic potash, is converted, in part, into α-methyl-imidazole. The mechanism of the reaction appears to consist of the conversion of dextrose into glyceric aldehyde, and of the latter into methylglyoxal, which then condenses with ammonia and formaldehyde to α-methyl-imidazole, and the fact that the yield of the latter is increased by addition of formaldehyde to the reacting substances, tends to confirm this view. By substituting acetaldehyde for formaldehyde, the author has obtained α-μ-dimethyl-imidazole (together with the α-methyl-imidazole)

With regard to French trade with the United Kingdom, further figures show a decrease in the value of imports of chemicals into France from £950,000 in 1904 to £913,000 in 1905. Indiarubber, however, increased from £605,000 to £831,000, and indiarubber goods from £374,000 to £411,000. Coal-tar exports from England to France in the two years were valued at £272,000 and £275,000 respectively. Among the exports from France to the United Kingdom, chemicals increased in value from £617,000 to £699,000; oils, other than essential oils, from £112,000 to £221,000, and caoutchouc and gutta-percha from £319,000 to £533,000. Essential oils, on the other hand, decreased from £164,000 to £139,000.

During the first six months of 1906 (as compared with those of 1905) French imports of rubber increased by £627,240, and chemicals by £62,960; sodium nitrate, oil-seeds, vegetable and mineral oils, and minerals showed falls in value. Exports of raw sugar increased £447,800 in value, and of refined, £449,560. Exports of minerals rose £66,240 in value.

GERMAN CHEMICAL INDUSTRIES IN 1905.

Bd. of Trade Commercial Series, No. 20, Nov. 25, 1906.

The total number of chemical works of all kinds in Germany increased last year from 8004 to 8278, and the number of hands employed therein from 179,792 to 188,386. The total amount paid in wages rose from £9,068,627 to £9,681,372. As regards the foreign trade both in chemical raw materials and in chemical manufactures, the total value of the imports rose last year from £18,509,807 to £21,117,647, an increase of 14·1 per cent.; whilst the total value of the exports rose from £23,210,784 to £26,583,333, an increase of 14·5 per cent. This increase was largely due to the then approaching alteration in the German tariff (which came into force last March), for the increase in imports and exports in the previous year had been 7 per cent. and 5 per cent. respectively (*cf.* this J., 1906, 1178) Whilst there was an improvement in the alkali and acid industry and business in soda was satisfactory, the condition of the potash industry was less favourable, because potash made from potassium chloride had to compete with caustic potash lye and with molasses-ash, and, at times, with Russian and Bohemian potash. The price of ferrocyanide salts kept low, but an improvement is anticipated owing to reduction of output. The demand for sulphuric acid was brisk, especially on the Rhine and in Westphalia, where the output of ammonium sulphate from coke works had largely increased. In spite of this, prices remained as before, the manufacturers being already committed at low prices. The strong demand for nitric acid by colour and explosive works continued, but prices did not keep pace with the rise in the raw material. Business in pharmaceutical, photographic, scientific and technical preparations was not favourable. There was a slight falling off in comparison with 1904, although sales were brisk, but keen competition and foreign hostile tariffs prevented the industry from recouping the increased cost of labour and raw materials. This was especially the case in regard to alkaloids and pharmaceutical products, the consumption of which rose considerably both in Germany and abroad, but suffered from severe competition, especially on the part of the French manufacturers. The attention of the industry in France was drawn by foreign exhibits at the Paris Exhibition to compounds such as cocaine, theobromine, pilocarpine, physostigmine, &c., and now, under the protection of a high import duty, the French are able to place their superfluous output abroad and compete against Germany. The condition of the photographic preparations industry is similar, especially in regard to sensitised silver paper, the price of which had to be reduced in view of American and Belgian competition. The German import duty is said to have afforded insufficient protection against such competition, for the high tariffs of the United States, Spain, France, and Austria-Hungary enabled manufacturers there to export some of their output at low prices. The oil-lacquer and oil-varnish industries, as well as mineral and lacquer-paints, sold well in consequence of activity in the building trade, but without any marked increase in output. The same may be said of organic acids and spirit preparations, the export of which suffered not only from the higher duties levied abroad, but also from the favour which is said to be given to the foreign trade by the German spirit ring. Essential oils have risen in price as consumption increases, and will probably go higher, since the new commercial treaties do not seriously affect this industry, and the new German Customs tariff now allows spice seeds (such as aniseed, fennel, coriander, &c.) to come in free of duty for this manufacture. The manufacture of artificial silk still further developed during the past year, and now promises to become profitable. The aniline dyestuff industry, the average output of which rose from 11·68 per cent. to 13·54 per cent., was entirely satisfactory. Exports, which form the greater part of the output, are increasing, and to this result the rapid advance of German synthetic indigo has materially contributed. Business in artificial manures was on the whole good, and profits rose from 8·66 per cent. to 9 per cent. The demand for superphosphates was brisk, and consumption was about 5 per cent. greater than in the previous year. Prices rose owing to mutual agreement among the manufacturers, but the rise of 40 per cent. in raw materials for all factories which had failed to protect themselves in time, prevented general improvement. Consumption of Thomas meal kept pace with increased production of Thomas slag; this manure also, which, on account of its cheapness, had interfered with the use of superphosphates, rose in price. After some fluctuation, there was a further rise in the price of ammonium sulphate, the production of which, in the last few years, has risen about 150,000 tons. Business in explosives was unaltered, but profits rose from 10·4 per cent. to 11·96 per cent. The match industry, which for a long time has had to be content with very modest profits, also improved. The prohibition of the use of yellow phosphorus, which is to come into force in 1907, will probably increase the demand for safety matches. The lignite industry was satisfactory in 1905, profits increasing from 7·38 per cent. to 7·64 per cent. Business in paraffin oils was profitable, and the consumption of this oil by Diesel motors increased. The sale of paraffin and of paraffin candles was normal. The indiarubber industry was affected by the supply of raw material failing to keep pace with the demand, and by a rise in price owing to sources of supply becoming more and more distant. Prices of manufactured india-rubber remained low, partly owing to competition amongst india-rubber manufacturers. In October the latter agreed to raise prices 10 per cent. and this has been accepted by the consumers. Nevertheless, the German india-rubber industry is not yet regarded as satisfactory. Profits for 1905 were only 7·95 per cent., as against 8·92 in 1904.

New Books.

PORTLAND CEMENT: ITS COMPOSITION, RAW MATERIALS, MANUFACTURE, TESTING, AND ANALYSIS. By RICHARD K. MEADE, Chemist to the Dexter Portland Cement Company, &c. The Chemical Publishing Company, Easton, Pa., U.S. America. 1906. Price 14*s.* 6*d.*

8vo volume, containing 376 pages of subject matter, an appendix, covering four pages, and an alphabetical index. There are 100 illustrations. The subject matter is classified as follows:—I. History of the Development of the American Portland Cement Industry. MANUFACTURE. II. Chemical Composition of Portland Cement. III. Raw Materials. IV. Proportioning the Raw Materials. V. Quarrying, Excavating, Drying, and Mixing the Raw Materials. VI. Grinding the Raw Material, and Grinding Machinery. VII. Kilns and Burning. VIII. Cooling and Grinding the Clinker; Storing and Packing the Cement, &c. ANALYTICAL METHODS. IX. Analysis of Cement. X. Analysis of Cement Mixtures, Slurry, &c. XI. Analysis of the Raw Materials. PHYSICAL TESTING. XII. Inspection of Cement. XIII. Specific Gravity. XIV. Fineness. XV. Time of setting. XVI. Tensile Strength. XVII. Soundness. MISCELLANEOUS. XVIII. Detection of Adulteration in Portland Cement. XIX. Trial Burnings.

THE NEW PHYSICS AND CHEMISTRY: A SERIES OF POPULAR ESSAYS ON PHYSICAL AND CHEMICAL SUBJECTS. By W. A. Shenstone, F.R.S. Smith, Elder & Co., 15, Waterloo Place, London. 1906. Price 7*s.* 6*d.* net.

8vo volume, containing 360 pages of subject matter, sub-divided under the following heads:—I. Matter, Motion, and Molecules. II. Some recent Speculations on the Constitution of Matter. III. Some recent theories of the Ether. IV. Modern Theories of Light. V. Weighing a World VI. On Weighing Atoms. VII. Some aspects of the new Chemistry. VIII. The Mechanics of Chemical Change. IX. Radium. X. Radium, and the Interpretation of Radio-active Changes. XI. Carbon and the Shapes of Atoms. XII. Ferments and Fermentations. XIII. About Solutions. XIV. The Origin of Life.

CLAYS: THEIR OCCURRENCE, PROPERTIES, AND USES, WITH SPECIAL REFERENCE TO THOSE OF THE UNITED STATES. By HEINRICH RIES, Ph.D., Assistant Professor of Economic Geology in Cornell University, &c. John Wiley & Sons, New York, U.S. America. 1906. Chapman & Hall, Ltd., London. Price 21*s.* net.

LARGE 8vo volume, containing 467 pages of subject matter, with 141 illustrations, and the alphabetical index. The subject matter is arranged according to the following scheme:—I. Origin of Clay. II. Chemical Properties of Clays. III. Physical Properties of Clay. IV. Kinds of Clay. V. Methods of Mining and Manufacture. VI. Distribution of Clay in the United States: Alabama and Louisiana. VII. Maine, North Carolina. VII. North Dacota to Wyoming. VIII. Fuller's Earth.

HERMANN VON HELMHOLTZ. By LEO KOENIGSBERGER Translated by FRANCES A. WELBY. With a Preface by LORD KELVIN. The Clarendon Press, Oxford. 1906. Price 16*s.* net.

ROYAL 8vo volume, containing 440 pages of subject matter, with three portraits. This work is a Biography of Helmholtz. At the close of his Preface, Lord Kelvin adds, "The Oxford University Press has earned the gratitude of all English-speaking scientific workers in giving them this English version of the very valuable and interesting Life of Helmholtz, by Dr. Königsberger."

THE PRINCIPLES OF QUALITATIVE ANALYSIS. From the Standpoint of the theory of Electrolytic Dissociation and the Law of Mass Action. By WILHELM BÖTTGER, Privatdocent in the University of Leipsic. Translated with the Author's sanction, and revised with his co-operation by William Gabb Smeaton, Instructor in General Chemistry in the University of Michigan. Rebman, Limited, 129, Shaftesbury Avenue, London, W.C. 1906. Price 9*s.*

8vo volume, containing frontispiece (Plate of Spectra), dedication to W. Ostwald, 289 pages of subject matter, 10 illustrations, and an alphabetical index. The subject matter is subdivided as follows:—Introduction. I. Testing a Solution for Metals. II. Testing a Solution for Anions. III. The complete Analysis of a given Unknown: (i.) Preliminary or Dry Tests, (ii.) To bring Solids into Solutions. IV. The Rare Elements. V. Analytical Tables.

DIE HARZE UND DIE HARZBEHAELTER, MIT EINSCHLUSS DER MILCHSAEFTE. Historisch-kritische und experimentelle in Gemeinschaft mit zahlreichen Mitarbeitern ausgeführte Untersuchungen. Von A. Tschirch. Zweite stark erweiterte Auflage. Gebrüder Borntraeger's Verlag, Leipzig. 1906. Price M.32.

Two 8vo volumes, Vol. I. and Vol. II. Vol. I. containing 1,092 pages of subject matter, and Vol. II. 141 pages, and the alphabetical index. The text is illustrated with 104 engravings. The subject matter is classified as follows:—I. CHEMISTRY OF THE RESINS. II. THE AUTHOR'S OWN INVESTIGATIONS (A. Resinotannolresins or Tannolresins. B Resene-resins. C. Resinolic acid Resins. D. Resinolresins E. Aliphatoresins (Fat-resins). F. Chromoresins (Colour Resins). G. Enzymoresins. H. Glucoresins. I. Lactoresins (Milky juices. Guttapercha group. Caoutchouc group). Chemistry of Caoutchouc. J. Pseudoresins. K. Unclassified resins. Vol. II. is devoted to the botanical aspects of the subject.

HOME OFFICE. VENTILATION OF FACTORIES AND WORKSHOPS. Illustrations of Methods of Dust Extraction in Factories and Workshops. Compiled by Commander Sir Hamilton P. Freer-Smith, R.N. (Late H.M. Superintending Inspector of Factories). Darling and Son, Ltd., 34—40, Bacon Street, London, E. 1906. Price 4*s.* 6*d.* Purchaseable directly or through any bookseller, from Wyman and Sons, Ltd., Fetter Lane, London, E.C., and 32, Abingdon Street, Westminster, London, S.W., or Oliver and Boyd, Edinburgh, or E. Ponsonby, 116, Grafton Street, Dublin.

COAL TABLES. 1905. Wyman and Sons, Fetter Lane, London, E.C. Price 6d.

THIS is the twelfth number of a publication annually prepared in the Commercial, Labour, and Statistical Department of the Board of Trade, showing the production and consumption of coal in the principal countries of the world during each of the years from 1885 to 1905, or to the most recent years for which the figures are available. In addition to statistics of production and consumption, particulars are also given of the average value per ton at the collieries, the number of persons employed in coal mining, coal imports and exports, &c. Statistics of lignite production and petroleum production in certain countries are also contained in the return (see also page 1209-1210.)

LIST OF COUNCIL AND OFFICERS.

President.

Eustace Carey, The Groves, Grassendale Park, near Liverpool.

Vice-Presidents.

Dr. L. Baekeland, Snug Rock, North Broadway, Yonkers, N.Y., U.S.A.

Sydney, N.S.W. :

Chairman .. Dr. R. Greig Smith, Linnæan Society's House, Elizabeth Bay, Sydney.

Secretary .. T. U. Walton, Colonial Sugar Refining Co., O'Connell Street, Sydney.

Yorkshire :

Chairman .. F. W. Branson, Wynneholme, Far Headingley, Leeds.

Secretary .. Thos. Fairley, 17, East Parade, Leeds.

Honorary Treasurer.

Samuel Hall, East London Soap Works, Bow, E.

Honorary Foreign Secretary.

Dr. Ludwig Mond, F.R.S., 20, Avenue Road, Regent's Park, London, N.W.

General Secretary.

Chas. G. Cresswell, Palace Chambers, Westminster, S.W. (Telegraphic address:—59, Palatable, London. Telephone No. 715, Victoria.)

Editor.

Watson Smith, 34, Upper Park Road, Haverstock Hill, London, N.W.

LIST OF MEMBERS.

THE MEMBERSHIP ON FEBRUARY 28, 1907 = 4422.

NOTE: "O.M." MEANS "ORIGINAL MEMBER."

1903. Abraham, Herbert, 13, West 89th Street, New York City, U.S.A., Chemist.
1902. Acker, Chas. E., 105, Gluck Building, Niagara Falls, N.Y., U.S.A., Manufacturer.
1903. Ackermann, Franz W., 86, Pierrepont Street, Brooklyn, N.Y., U.S.A., Chemist.
1903. Acton, J. Rowland, Wicklewood, Maze Road, Kew, S.W., Civil Servant.
1892. Adams, Arthur, Kelvin House, Edgbaston Road, Smethwick, near Birmingham, Science Lecturer.
1897. Adams, Thos. H., Endon Villa, Victoria Avenue, Borrowash, near Derby, Analyst.
1905. Adams, William W., Norwood, Mass., U.S.A., Leather Works Manager.
1895. Adamson, G. P., c/o The Baker and Adamson Chemical Co,, Easton, Pa., U.S.A., Manufacturing Chemist.
1891. Adcock, S. R., St. Helens Smelting Co., Atlas Court, St. Helens, Lancashire, Analytical Chemist.
1901. Addison, Leonard, c/o Messrs. Burt, Boulton, and Haywood, Selzaete, Belgium, Chemist.
1898. Adgate, M., Naugatuck, Conn., U.S.A., Chemist.
1898. Adiassewich, Alex. V., 14, Addison Park Mansions, Kensington, W., Oil Engineer.
1896. Adler, Dr. Leon N., Adler Colour and Chemical Works, 100, William Street, New York City, U.S.A., Manufacturing Chemist.
1907. Adley, Geo. S., Storer's Wharf, Poplar, London, E., Varnish Manufacturer.
1888. Adriance, Dr. John S., The Union League Club, New York City, U.S.A., Analytical Chemist.
1899. Adrot, Léon, Woodside, Long Island, N.Y., U.S.A., Chemist.
1886. Aitken, J. B., Gerard's Fold Chemical Works, Widnes, Chemical Manufacturer.
1884. Akitt, Thos., Mijnbouw Maatschappij Katahoen, Lebong Soelit, Benkoelen, Sumatra, Chemist.
1883. Albright, G. S., Bromesberrow Place, Ledbury, Chemical Manufacturer.
O.M. Albright, W. A., 29, Frederick Road, Edgbaston, Birmingham, Chemical Manufacturer.
1906. Alcock, Frank H., 9, Broad Street Corner, Birmingham, Analyst.
1891. Alcock, Jno. W., Central Brewery, Mott Street, Birmingham, Maltster and Brewer.
1902. Alden, Frederick, 342, 22nd Avenue, Milwaukee, Wis., U.S.A., Chemist.
1898. Alden, John, Chemical Laboratory, Pacific Mills, Lawrence, Mass., U.S.A., Chemist.
1906. Alder, H. W., 18, Holyhead Road, Coventry, Works Chemist.
1900. Aldrich, Roger C., c/o Franklin H. Kalbfleisch Co., Elizabeth, N.J., U.S.A., Mechanical Engineer.
1890. Aldrick, Edwin John, 53, Alpha Road, West Ferry Road, Millwall, E., Works Sub-Manager.
1905. Aleon, Armen P., 372/4, Atlantic Avenue, Boston, Mass., U.S.A., Dyestuff and Chemical Merchant.
1899. Alexander, D. Basil W., 1020, Date Street, Los Angeles, Cal., U.S.A., Chemist.
1900. Alexander, Jerome, c/o National Gum and Mica Co., 502-510, West 45th Street, New York City, U.S.A., Chemist.
1883. Alexander, W. T., Crumnock, Eccles, Manchester, Drysalter.
1906. Allan, David, c/o Price's Patent Candle Co., Ltd., Belmont Works, Battersea, S.W., Chemist.
1891. Allan, F. H. Tielke, Portobello House, Wakefield, Analytical Chemist.
1898. Allan, John, 55, Northen Grove, West Didsbury, near Manchester, Chemist.
1902. Allbright, Wm. B., 5139, Lexington Avenue, Chicago, Ill., U.S.A., Chemical Engineer.
O.M. Alldred, C. H., 8, St. Margaret's Road, Plumstead Common, Kent, Analytical Chemist.
1898. Alleman, Dr. Gellert, Swarthmore College, Swarthmore, Pa., U.S.A., Professor of Chemistry.
1903. Allen, Chas. A., 95, Manor Road, Darwen, Lancashire, Chemist.
1902. Allen, Chas. D., jun., 541, 6th Street, Brooklyn, N.Y., U.S.A., Chemist.
O.M. Allen, J., 164, Upper North Street, Poplar, E., Manufacturing Chemist.
1901. Allen, R. F., 1241, South 47th Street, Philadelphia, Pa., U.S.A., Chemist.
1889. Allen, R. L., Hillside, and (Journals) c/o Brunner, Mond & Co., Ltd., Sandbach, Cheshire, Analytical Chemist.
1904. Allen, Thos. E., c/o American Aristotype Co., Jamestown, N.Y., U.S.A., Chemist.
1900. Allen, Wilfrid T., Allington, Bexley, Kent, Director.
1893. Allerton, Rt. Hon. Lord, F.R.S. (Journals), Allerton Hall, near Leeds; and c/o W. L. Jackson and Sons, Ltd., Buslingthorpe, Leeds, Tanner.
O.M. Allhusen, A., Gateshead-on-Tyne, Chemical Manufacturer.
1886. Allibon, G. H., 35, Eglantine Avenue, Belfast, Ireland, Chemical Works Manager.
1887. Alliott, J. B., Messrs. Manlove, Alliott, and Co., Ltd., Nottingham, Mechanical Engineer.
1895. Allison, Wm. O., 100, William Street, New York, City, U.S.A., Publisher of "Oil, Paint and Drug Reporter."
1905. Allpass, Jas., c/o The Clayton Aniline Co., Ltd., Clayton, Manchester, Secretary.
1904. Alpers, Wm. C., Broadway and 31st Street, New York City, U.S.A., Manufacturing Chemist.
1889. Alpiar, Agop, Smyrna, Asia Minor, Morphia Manufacturer.
1899. Alsop, Wm. K., 137, Grove Street, Stamford, Conn., U.S.A., Chemist.
1901. Alston, Robt. A., c/o Glencairn Main Reef G. M. Co., P.O. Box 191, Germiston, Transvaal, Mining Engineer.
1904. Alton, W. Lester, 11, Briar Walk, Putney, S.W., Chemist.
1898. Ambler, Chas. Taaffe, Dharhara Station, E. I. Ry., Bengal, India, Mine Owner and Contractor.
1905. Amory, L. H., c/o Messrs. J. Heathcoat and Co., Tiverton, Devon, Lace Manufacturer.
1900. Anderson, Jas. W., The Paddock, Halling, near Rochester, Kent, Analytical Chemist.
1889. Anderson, Robt. T. R., 42, Roslea Drive, Dennistoun, Glasgow, Technical Chemist.
1894. Anderson, Dr. W. Carrick, 7, Scott Street, Garnet Hill, Glasgow, Consulting Chemist and Metallurgist.
O.M. Anderton, G. H., Howendyke, Howden, Yorks, Chemical Manufacturer.
1905. Andreae, Dr. E. P., Crestalta, Champion Hill, London, S.E., Chemist.

1889. Andrews, C. W., c/o The John Crerar Library, Wabash Avenue and Washington Street, Chicago, Ill., U.S.A., Librarian.
1904. Andrews, Geo. D., c/o J. & J. Colman, Ltd., Carrow Works, Norwich, Chemist.
1903. Andrews, Wm. H., 79, Tonawanda Street, Buffalo, N.Y., U.S.A., Manager (Varnish Works).
1903. Anfilogoff, N. A., St. Vincent's, Orsett Road, Grays, and (Journals) Central Wharf, Bow, E., Chemist.
O.M. Angell, J., 6, Beaconsfield, Derby Road, Withington, Manchester, Chemical Lecturer.
1892. Annandale, C. J. R., The Briary, Shotley Bridge, Co. Durham, Paper Maker.
1883. Annandale, Jas. H., Polton Paper Works, Midlothian, N.B., Paper Maker.
1887. Annison, R. H., 16, Water Lane, Tower Street, London, E.C., Master Lighterman.
1894. Ansbacher, L. A., 253, Broadway, New York City, U.S.A., Colour Manufacturer.
1903. Anspach, Dr. R., 14, Oakroyd Terrace, Manningham, Bradford, Chemist.
1902. Anthony, John, 82, Bay Street, Toronto, Canada.
1899. Appleby, C. W., Farnworth, near Widnes, Lancashire, Pith and Size Manufacturer.
1904. Appleby, Jos., Farnley, Moor Lane, Great Crosby, Liverpool, Flour Miller.
1906. Appleby, L. C. B., c/o Messrs. R. Bishop & Sons, Newark-on-Trent, Maltster.
1895. Appleby, Prof. W. R., 911, 5th Street, S.E., Minneapolis, Minn., U.S.A., Professor of Mining and Metallurgy.
1894. Appleton, H. A., 63, Rosedale Road, Forest Gate, E., Analytical Chemist.
1897. Appleton, Dr. Jno. Howard, 209, Angell Street, Providence, R.I., U.S.A., Professor of Chemistry.
1900. Appleyard, Geo. H., c/o British Oil and Cake Mills, Ltd., 151, Cleveland Street, Hull, Chemist.
1905. Appleyard, Jas. R., Royal Technical Institute, Salford, Lecturer.
1904. Appleyard, Percy, Albany, West Australia, Chemist.
1903. Arbogast, Ralph, c/o Edison Storage Battery Co., Silver Lake, N.J., U.S.A., Chemist.
1901. Archbold, Dr. Geo., c/o J. D. Conover Co., 101, Franklin Street, New York City, U.S.A., Chemist.
O.M. Archbutt, Leonard, The Yews, Madeley Street, Derby, Analytical Chemist.
1899. Archdale, T. Henry, 77, Queen's Road, Blackburn, Manager of Tar and Ammonia Works.
1904. Archdale, Wm., 21, Oldham Road, Miles Platting, Manchester, Manager of Chemical Works.
1901. Ardagh, Edw. G. R., School of Practical Science, Toronto, Canada, Chemist.
1900. Ardern, Edw., 4, Westbourne Road, Urmston, Manchester, Chemist.
1901. Argall, Philip, 728–732, Majestic Buildings, Denver, Colo., U.S.A., Manager (Gold Extraction Works).
1902. Armstrong, Edward E., Pennsylvania Salt Manufacturing Co., Natrona, Pa., U.S.A., Manufacturing Chemist.
1905. Armstrong, Dr. E. Frankland, Lodge Hotel, King's Road, Reading, Works Chemist.
1899. Armstrong, Richard, Saul Street Soap Works, Preston, Lancashire, Soap Manufacturer.
1905. Armstrong, Theodore, 115, Chestnut Street, Philadelphia, Pa., U.S.A., President, Penn. Salt Manufacturing Co.
1905. Arnold, Frank L., 32, School Street, North Woburn, Mass., U.S.A., Chemist.
1901. Arnold, G. Edmund, 6, Kingsfield Terrace, Faversham, Kent, Manager (Cotton Powder Co., Ltd.).
1899. Arnott, G. W. Campbell, 114, Victoria Street, Toronto, Canada, Agricultural Chemist.
1903. Arnott, J. S., Moros, 42, 2°, Gijon, Spain, Chemist and Metallurgist.
1901. Arundel, Arthur S. D., Penn Street Works, Hoxton, N., Paper Box Manufacturer.
1901. Asano, K., 25, Kitachoyaoho, Kyobashi, Tokyo, Japan, Mining Chemist.
1906. Ash, Chas. S., 180, Townsend Street, San Francisco, Cal., U.S.A., Chemist.
1903. Ashley, Frank R., Western Chemical Manufacturing Co., Denver, Colo., U.S.A., Chemist.
1900. Ashley, Harrison Everett, Newell, West Va., U.S.A., Metallurgical Chemist.
1900. Ashton, Jas., Rhodes Farm, Whitefield, Manchester, Chemist and Manager.
1890. Ashton-Bost, W.D. *See* Bost, W. D. Ashton.
1885. Ashwell, J. H., 117, Waterloo Crescent, The Forest, Nottingham, Bleacher and Dyer.
1894. Ashworth, Arthur, Fernhill Chemical Works, Bury, Lancs., Chemical Manufacturer.
1903. Ashworth, Jno. B., 11, The Promenade, Egremont, Cheshire, Manager.
1907. Aspey, Urban, jun., New Station Soap Works, School Close, Leeds, Works Manager and Chemist.
1898. Aspinall, Thos., 62, Gilnow Road, Bolton, Analytical and Manufacturing Chemist.
1900. Aston, Bernard C., Agricultural Department, Wellington, New Zealand, Chemist.
1891. Atkins, C. E., Teignmace, Byculiah Park, Enfield, N., Chronometer Maker.
1885. Atkinson, A. J., 44, Stuart Street, Cardiff, Analytical Chemist.
1902. Atkinson, Edwin B., Furze Glen, Lambert Road, Great Grimsby, Lecturer in Chemistry.
1905. Atkinson, James P., Dept. of Health, 55th Street and 6th Avenue, New York City, U.S.A., Chemist.
1900. Atkinson, Jno. W., Betteravia, Cal., U.S.A., Chemist.
1905. Atteaux, F. E., 176, Purchase Street, Boston, Mass., U.S.A., Dyestuff Importer.
O.M. Attfield, Dr. J., F.R.S., Ashlands, Watford, Herts.
1900. Atwood, Frank W., 216, Milk Street, Boston, Mass., U.S.A., Chemist.
1895. Auchterlonie, Wm., jun., c/o Clark Thread Co., Newark, N.J., U.S.A., Dyeworks Manager.
1901. Auden, Dr. H. A., Westwood, Grassendale, Liverpool, Chemist.
1897. Auger, Chas. L., 425, Park Avenue, Paterson, N.J., U.S.A., Silk Dyer.
1887. Austen, Prof. Peter T., (Journals) 204, West 86th Street, and (communications) 89, Pine Street, New York City, U.S.A., Professor of Chemistry.
1902. Austin, J. H., Allscott, Wellington, Shropshire, Analytical Chemist.
1901. Auty, Albert M., c/o John Smith and Sons, Ltd., Field Head Mills, Bradford, Chemist.
1902. Avery, D., Working Mon's College, Melbourne, Vic., Australia, Teacher of Chemistry.
1890. Aykroyd, H. E., Scaitcliffe, Queen's Road, Ilkley, Yorks, Dyer.
1899. Aylsworth, Jonas W., 223, Midland Avenue, East Orange, N.J., U.S.A., Chemist.
1903. Ayres, W. J., P.O. Box 187, Pernambuco, Brazil, Sugar Expert.

B

1904. Babb, Edward E., 41, Central Wharf, Boston, Mass., U.S.A., Food Analyst.
1895. Bacon, Nathaniel T., Peace Dale, Rhode Island, U.S.A., Chemical Engineer.
1903. Bacon, R. A., Richmond Hill, Long Island, N.Y., U.S.A., Manufacturing Chemist.
1897. Bacon, Wm., 4, New Court, Lincoln's Inn, W.C., Chemist.
1897. Badock, Stanley H., Holmwood, Westbury on Trym, near Bristol, Smelter.
1898. Baekeland, Dr. Leo, Snug Rock, North Broadway, Yonkers, N.Y., U.S.A., Manufacturing Chemist.
1902. Baer, Dr. Samuel H., 212, South 7th Street, St. Louis, Mo., U.S.A., Consulting Chemist.
1903. Bailey, Prof. E. H. S., The Library, Kansas State University, Lawrence, Kas., U.S.A., Professor of Chemistry.
1885. Bailey, Edwin M., Almond Hill, Pumpherston, Mid-Calder, N.B., Technical Chemist.
1883. Bailey, Dr. G. H., Marple Cottage, Marple, Cheshire, Chemical Lecturer.

1903. Bailey, Harold J., Maritime Coke Works, Pontypridd, S. Wales, Chemist.
1898. Bailey, Henry, 6, Elsenham Road, Wimbledon Park, S.W., Analytical Chemist.
1906. Bailey, Ralph, W., c/o Messrs. Stillwell & Gladding, 55, Fulton Street, New York City, U.S.A., Chemist.
1888. Bailey, Dr. T. Lewis, Glassford Creek, *viâ* Miriam Vale, Queensland, Australia, Chemist.
1888. Bailey, Sir W. H., Albion Works, Salford, Manchester, Chemical Engineer.
1888. Bailey, Walter P., Empresa de Gas, 13, San Roque, Seville, Spain, Chemical Engineer and Manager.
1902. Bain, Jas. Watson, School of Practical Science, Toronto, Ont., Canada, Chemist.
1890. Baird, H. Harper, 14, Cross Street, Hatton Garden, London, E.C., Laboratory Furnisher.
1902. Baird, Dr. Julian W., Massachusetts College of Pharmacy, Boston, Mass., U.S.A., Professor of Chemistry.
1891. Baird, Wm., c/o Lewis Berger and Sons, Ltd., Homerton, N.E., Technical Chemist.
1895. Baird, W. Raymond, 271, Broadway, New York City, U.S.A., Patent Lawyer.
1890. Bairstow, John, Burley, Queen's Park, Chester, Chemical Works Manager.
1903. Baker, Arthur, 96, Blackburn Road, Darwen, Lancs., Chemist.
1902. Baker, Chas. F., Technical College, Sunderland, Lecturer in Chemistry.
1901. Baker, F. Guy Stirling, Marryatt's Lodge, The Forest, Snaresbrook, Essex, Student.
1883. Baker, Harry, Epworth House, Moughland Lane, Runcorn, Analytical Chemist.
1905. Baker, Henry, 18, Booth Street, Manchester, Secretary.
1899. Baker, H. Fenimore, c/o Thomsen Chemical Co., Baltimore, Md., U.S.A., President.
1904. Baker, John T., c/o J. T. Baker Chemical Co., Phillipsburg, N.J., U.S.A., Manufacturing Chemist.
1892. Baker, Julian L., Staincsbury Holt, Kingston Road, Staines, Brewing and Sugar Chemist.
1886. Baker, Theodore, P.O. Box 71, Wilmington, Del., U.S.A., Analytical Chemist.
1898. Baldwin, Abram T., Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Manufacturer.
1903. Baldwin, F. H., Bergenport Chemical Works, Bayonne, N.J., U.S.A., Superintendent.
1903. Baldwin, Dr. H. B., 927, Broad Street, Newark, N.J., U.S.A., Chemist (Dept. of Public Health).
1903. Ball, S. F., Hull Avenue and 209th Street, New York City, U.S.A., Analytical Chemist.
1889. Ballantyne, Horatio, 75, Chancery Lane, London, W.C., Analytical and Consulting Chemist.
1903. Ballantyne, W. H., 111, Hatton Garden, London, E.C., Patent Agent's Assistant.
O.M. Ballard, Edw. G., 7, Godstall Chambers, Chester, Alkali Works Inspector.
1891. Ballinger, Jno., Free Library, Cardiff, Librarian.
1903. Baltzly, E. B., c/o Semet Solvay Co., Syracuse, N.Y., U.S.A., Superintendent.
O.M. Bamber, H. K., 9, Victoria Street, London, S.W., Consulting Chemist.
1894. Bamber, H. K. G., Ingress House, Greenhithe, Kent, Cement Works Chemist and Manager.
1898. Bamford, Harry, 70, Duckworth Terrace, Bradford, Yorks., Dyer.
1905. Bampton, Geo. F., Room 24, 68, Essex Street, Boston, Mass., U.S.A., Chemist.
1906. Bancroft, John, Wilmington, Del., U.S.A., Bleacher and Dyer.
O.M. Banister, H. C., Elmhurst, Blundellsands, near Liverpool, Chemical Works Manager.
1890. Banks, Jno. H., c/o Ricketts and Banks, 104, John Street, New York City, U.S.A., Mining Engineer.
1895. Bannan, John F., 59, Court Street, North Andover, Mass., U.S.A., Chemist (Woollen Mill).
1885. Banner, Samuel, 4, Ivanhoe Road, Liverpool, Petroleum Merchant.
O.M. Bannister, R., 59, Tregunter Road, South Kensington, S.W., Analytical Chemist.
O.M. Bannister, W., Victoria Lodge, Cork, Ireland, Manufacturing Chemist.
1901. Barber, Capt. René R., Georgetown, Ont., Canada, Analytical Chemist.
1906. Barbour, Robt. B., Eclipse Chemical Manufacturing Co., Chelmsford, Mass., U.S.A., Manager.
1892. Barden, Alf., Far Bank, Shelley, near Huddersfield, Glue and Size Maker.
1895. Bardwell, Fred. L., Massachusetts Institute of Technology, Boston, Mass., U.S.A., Assistant Professor of Chemistry.
1903. Baringer, Fred. J., Eagle White Lead Works, 1020, Broadway, Cincinnati, Ohio, U.S.A., Chemist.
1902. Barker, Hugh S., 32, Cumberland Avenue, Sefton Park, Liverpool, Laboratory Furnisher.
1905. Barker, Perry, c/o U.S. Fuel Testing Plant. Boiler Division, St. Louis, Mo., U.S.A., Chemist.
1895. Barlow, Clinton W., 103–105, Greene Street, New York City, U.S.A., Merchant.
1901. Barlow, John J., 177, Manchester Road, Accrington, Calico Printer's Chemist.
1899. Barlow, Wm., 311, Market Street, Droylsden, near Manchester, Analytical Chemist.
1906. Barnes, A. G., Grassmoor Collieries, Chesterfield, Colliery Proprietor.
1891. Barnes, Edward A., Sundalen, Aasenfjorden, Norway, Technical Chemist.
1901. Barnes, Fred., 2, Fairview, Canterbury Road, Sittingbourne, Kent, Paper Mill Chemist.
1905. Barnes, F. V., 44, Lucknow Avenue, Nottingham, Gas Works Chemist.
1884. Barnes, H. J., Phœnix Chemical Works, Hackney Wick, N.E., Manufacturing Chemist.
1884. Barnes, Jonathan, 301, Great Clowes Street, Manchester, Analytical Chemist.
O.M. Barnes, Jos., Green Vale, Westhoughton, near Bolton, Lancashire, Analytical Chemist.
1902. Barnett, Marcus S., Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Sugar Works Chemist.
1897. Barnett, Robt. E., 9, Virginia Road, Leeds, Headmaster (Leeds Technical School).
1898. Barnicott, Jas. A., Messrs. May and Baker Ltd., Garden Wharf, Church Road, Battersea, S.W., Chemical Manufacturer.
1904. Baron, Wm. Briscoe, c/o The Fuel Saving and Water Treating Co., Ltd., 2, Booth Street, Albert Square, Manchester, Chemist.
1901. Barr, Geo., c/o Trimble Dyeing and Printing Co., Philadelphia, Pa., U.S.A., Calico Printer.
O.M. Barr, J., Dinting Vale, Dinting, near Manchester, Chemical Manager.
1905. Barraclough, C. E., Wood View, Manningham, Bradford, Chemist.
1890. Barraclough, Wm. H., Beechwood, Mortomley, near Sheffield, Analytical Chemist.
1896. Barratt, J. Treeby, Bronheulog, Mostyn, North Wales, Chemist and Manager.
1890. Barrett, Arthur A., 5, Strada del Pozzo Leone, Messina, Sicily, Manufacturer of Essential Oils.
1890. Barrie, D. McLaurin, P.O. Box 193, Germiston, Transvaal, Analytical Chemist.
1900. Barrow, Jos., 13, The Grove, Bebington, Cheshire, Chemist.
1906. Barrs, Chas. E., 20, Carlingford Road, Hampstead, N.W., Analyst.
1905. Barry, Eugene, Ayer, Mass., U.S.A., Leather Manufacturer.
1893. Barton, G. E., c/o Whitall, Tatum, and Co., Flint Glass Works, Millville, N.J., U.S.A., Technical Chemist.
1900. Barton L. Edward, Broadway, cor. Thatcher Street, Albany, N.Y., U.S.A., Chemist.
1903. Bartripp, Geo. F., 20, Grove Road, Wanstead, Essex, Analytical Chemist.
1905. Baruch, Edgar, c/o Alta California Beet Sugar Co., Hamilton, Glenn Co., Cal., U.S.A., Chemical Engineer.

1895. Beskerville, Dr. Chas., College of the City of New York, New York, U.S.A., Professor of Chemistry.
1884. Bassett, H., 26, Belitha Villas, Barnsbury, N.
1899. Bassett, Wm. H., 146, Litchfield Street, Torrington, Conn., U.S.A., Chemist.
1890. Bate, William, "Ladbroke," Hayle, Cornwall, Technical Chemist (National Explosives Co., Ltd.).
1903. Bateman, A. H. 34, Bridge Avenue, Hammersmith, W., Chemist.
1903. Bates, C. O., c/o Coe College Library, Cedar Rapids, Iowa, U.S.A., Teacher of Chemistry.
1885. Batty, R. B., Wharncliffe, Erdington, near Birmingham, Nickel Works Manager.
1903. Baty, E. J., British Insulated and Helsby Cables, Ltd., Prescot, Lancs., Chief Chemist.
1903. Bauer, Geo. W., 632, Sacramento Street, San Francisco, Cal., U.S.A., Vice-President and Chemist (Hop and Malt Co.).
1906. Bauer, H. F., 809, McAllister Avenue, Waukegan, Ill., U.S.A., Chemist.
1900. Baur, Jacob, 67, Wells Street, Chicago, Ill., U.S.A., Liquid Carbonic Acid Manufacturer.
1898. Baxter, John G., 143, Milton Road, Gravesend, Kent, Chemist.
O.M. Baxter, W. H., Nuthurst, Streatham, S.W., Brewery Director.
1899. Bayly, Francis W., Assayer.
1904. Bayly, Harold G., Usine Ste. Madeleine, San Fernando, Trinidad, Analytical Chemist.
O.M. Baynes, J., Royal Chambers, Scale Lane, Hull, County and Borough Analyst.
1897 Beadle, Alec A., Greenbeys, Granville Road, High Barnet, Herts., Electro-Chemist.
1886. Beadle, Clayton, Halewood, Sideup, Kent, Consulting Chemist.
1890. Bealey, Adam C., c/o A. C. Bealey and Sons, Radcliffe, Lancashire, Bleacher and Alkali Manufacturer.
1904. Bean, Percy, 10, Marsden Street, Manchester, Analytical Chemist.
O.M. Beanes, E., Moatlands, Paddock Wood, Kent, Manufacturing Chemist.
1905. Beasley, Jno. K., c/o Hong Kong and Shanghai Banking Corporation, Ltd., Singapore, S.S., Metallurgical Chemist.
1883. Beaven, E. S., 5, Boreham Terrace, Warminster, Wilts, Maltster.
1897. Beaver, Chas. J., Holme Lea, Ashley Road, Hale, Cheshire, Chemist.
1898. Beck, Herbert H., 105, South Queen Street, Lancaster, Pa., U.S.A., Chemist.
1905. Beckers, Dr. Wm., 128, Duane Street, New York City, U.S.A., Chemist.
O.M. Beckett, G. H., Hartford, South Beach Avenue, Ardrossan, Scotland, Analytical Chemist.
1898. Beckett, Jos. H., Duffryn House, Ebbw Vale, Mon., Analytical Chemist.
1903. Beckwith, Edw. Pierrepont, Garrison on the Hudson, N.Y., U.S.A., Chemist.
1899. Bedford, Alf. C., 26, Broadway, New York City, U.S.A., Chemical Merchant.
1891. Bedford, Chas. S., Rocella, Westwood, Headingley, Leeds, Manufacturing Chemist.
1891. Bedford, Jas. E., Messrs. Wood and Bedford, Airedale Chemical Works, Leeds, Manufacturing Chemist.
O.M. Bedson, Prof. P. Phillips, Armstrong College, Newcastle-on-Tyne, Professor of Chemistry.
1901. Beebe, Murray C., University of Wisconsin, Madison, Wis., U.S.A., Engineer.
1901. Beevers, Clifford J., c/o Brotherton and Co., Ltd. Holmes Street, Dewsbury Road, Leeds, Analyst.
1899. Behr, Dr. Arno, 432, Arlington Court, Pasadena, Cal., U.S.A., Chemist.
1903. Behrend, F., 54, Front Street, New York City, U.S.A., Importer of Chemical Stoneware.
O.M. Beilby, George T., 11, University Gardens, Glasgow, Chemical Engineer.
1902. Bek, Lars, P., Goondi, Johnston River, North Queensland, Australia, Analytical Chemist.
1906. Belden, A. W., Fuel Testing Plant, St. Louis, Mo., U.S.A., Coke Expert.
1902. Bell, Edwin L., Grenzhausen, bei Coblentz, Germany, Manager.
1906. Bell, H. N., Tay Street, Invercargill, New Zealand, Company Manager.
1884. Bell, Sir Hugh, Bart., Middlesbrough-on-Tees, Soda and Iron Manufacturer.
1900. Bell, Hugh P., 3, Mincing Lane, London, E.C., Chemist.
O.M. Bell, J. Carter, Bank House, The Cliff, Higher Broughton, Manchester, Public Analyst.
1886. Bell, J. Ferguson, Derby Gas Light and Coke Co., Derby, Gas Engineer.
1907. Bell, Marcus, Commonwealth of Australia Offices, 72, Victoria Street, London, S.W., until June 15th; then Explosives Dept., 423, Flinders Lane, Melbourne, Victoria, Chemist.
1905. Bell, Miss M. M., Tulane University Library, New Orleans, La., U.S.A., Librarian.
1903. Bell, P. Carter, Millburn, N.J., U.S.A., Chemical Manufacturer.
1902. Bement, Alburto, American Trust Building, Chicago, Ill., U.S.A., Chemical Engineer.
O.M. Bendix, D., 371, Romford Road, Forest Gate, E., Managing Chemist, British Alizarin Co., Ltd.
1897. Benfey, Dr. Hans, 295, North Road, Clayton, Manchester, Manufacturing Chemist.
1903. Benham, Keith, Deans Hill, Stafford, Analytical and Consulting Chemist.
1902. Benjamin, Albert, Springbrook Works, Middleton Road, Oldham, Bleach and Dyeworks Manager.
O.M. Benjamin, Dr. M., Smithsonian Institution, Washington, D.C., U.S.A., Consulting Chemist, A.M.
1904. Benn, R. H. D., 16, Springfield Avenue, Westmount, Montreal, Canada, Analytical Chemist.
1906. Bennett, A. E. J., Bethel, Vermont, U.S.A., Leather Manufacturer.
1899. Bennett, Alex. H., c/o G. H. Ogston & Moore, Messina, Sicily, Chemist.
1901. Bennett, Arnold, c/o Montreal Steel Works, Ltd., Canal Bank, Point St. Charles, Montreal, Canada, Chemist.
1884. Bennett, Thos., Birch Vale, near Stockport, Calico Printer.
1902. Bennie, P. McN., P.O. Box 29, Niagara Falls, N.Y., U.S.A., Consulting Chemist.
1906. Benson, Richard W., Public Analysts' Laboratory, 67, Surrey Street, Sheffield, Analytical Chemist.
1905. Bentley, Prof. W. B., 42, Morris Avenue, Athens, Ohio, U.S.A., Professor of Chemistry.
1901. Bentley, Wm. H., 6, Woodbine Terrace, Irlam, near Manchester, Technical Chemist.
1890. Bentz, Ernest, 107, Shaw Lane, Dinting, near Manchester, Lecturer on Dyeing.
1905. Berge, Henry vom, c/o Schoellkopf & Co., Perry and Mississippi Streets, Buffalo, N.Y., U.S.A., Manager.
1884. Beringer, J. J., Basset Road, Camborne, Cornwall, Metallurgist.
1893. Berk, Fred. W., 1, Fenchurch Avenue, London, E.C., Chemical Manufacturer.
1900. Bermingham, Jno., jun., California Powder Works, Pinole, Contra Costa Co., Cal., U.S.A., Superintendent.
1889. Bernard, Jas., jun., c/o Chas. Hadfield, Viaduct House, Dinting, near Manchester, and (Journals) Ranipet, North Arcot, Madras Presidency, India, Chemical Works Manager.
1900. Berolsheimer, D. D., 11, East 59th Street, New York City, U.S.A., Chemist.
1906. Berry, A. J., 5, University Gardens, Glasgow, Student of Chemistry.
1897. Berry, Albert E., 62, Claremont Road, Forest Gate, Essex, Works Manager.
1883. Berry, E. E., Bordighera, Italy, Technical Chemist.
1889. Berry, G. F., Atlas Chemical Works, West Ferry Road, Millwall, E., Manager.
1903. Berry, W. C., 329, West 53rd Street, New York City, U.S.A., Chemist.

1886. Best, Dr. T. T., Hardshaw Brook Chemical Works, St. Helens, Lancashire, Technical Chemist.
1901. Betts, Anson G., Troy, N.Y., U.S.A., Chemist.
O.M. Bevan, E J., 4, New Court, Lincoln's Inn, London, W.C., Public Analyst and Consulting Chemist.
1900. Bevan, Jno. W., Risedale, St. James' Crescent, Swansea, Manager of Metallurgical Works.
O.M. Beveridge, Jas., c/o Miramichi Pulp and Paper Co., Ltd., Chatham, N.B., Canada, Pulp and Paper Manufacturer.
1900. Bevington, Col. S. B., 42, St. Thomas Street, Southwark, S.E., Leather Dresser.
1893. Bhaduri, Prof. K., Canning College, Lucknow, India, Professor of Chemistry.
1898. Bhattacharyya, Haripada, Gun and Shell Factory, Ishapore, Bengal, India, Chemist.
1902. Biach, Dr. Ludwig K., 223, Central Avenue, Norwich, Conn., U.S.A., Chemist and Colorist.
1896. Bibby, John, c/o J. Bibby & Sons, Formby Street, Liverpool, Student.
O.M. Bickerdike, W. E., Bryer's Croft, Wilpshire, near Blackburn, Manufacturing Chemist.
1901. Bielecki, Dr. Jan, "Chemik Polski," 66, Krakowski Przedmiescie, Warsaw, Poland, Chemist.
1903. Bierwirth, L. W., c/o E.I. du Pont & Co., Central National Bank Building, Wilmington, Del., U.S.A., Civil Engineer.
1884 Biggart, J. Wm., 29, Cathcart Street, Greenock, N.B., Analytical Chemist.
1891. Biggart, Wm. L., Rossarden, Kilmalcolm, N.B., Public Analyst.
O.M. Biggs, B., 110, Cannon Street, London, E.C., Chemical Merchant.
O.M. Billing, H. S., 42, Kingsley Road, Mutley, Plymouth, Analytical and Managing Chemist.
1896. Billings, Edgar F., 178, Freeport Street, Dorchester, Mass., U.S.A., Manufacturing Chemist.
1896. Billington, Chas., jun., Heimath, Porthill, Longport, Staffordshire, Metallurgist.
1898. Binney, Harold, Washington Life Building, 141, Broadway, New York City, U.S.A., Patent Lawyer.
1902. Binning, Stevenson, 101, Shooter's Hill Road, Blackheath, S.E., Technical Chemist.
1903. Binns, John H., Thornfield, Mystic Pond, Methuen, Mass., U.S.A., Dyer and Finisher.
1896. Bird, Arthur W., c/o S. Berger & Co., Bromley-by-Bow, E., Works Engineer.
1907. Bird, Charles S., jun., East Walpole, Mass., U.S.A., Paper Maker.
1896. Bird, Jno. B., Minver House, 61, Bateman Street, Cambridge, Manure Manufacturer.
1903. Bird, Thos., 59A, Brook Street, Grosvenor Square, London, W., Surgeon.
1902. Bird, W. Robt., 217, Newport Road, Cardiff, Oil Merchant.
1895. Bird, Wm. R., (communications) 125, Goddard Avenue; (Journals) Laboratory, G.W.R. Works, Swindon, Wilts, Analytical Chemist.
1885. Birley, R. K., c/o Chas. Macintosh and Co., Ltd., Cambridge Street, Manchester, India-rubber Manufacturer.
1883. Bishop, A. Conway, Three Mills Lane, Bromley-by-Bow, E., Manufacturing Chemist.
1884. Bishop, Fred, c/o Burmah Oil Co., Rangoon, Burmah, Technical Chemist.
1903. Bishop, Howard B., 609, Greene Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1903. Bishop, J. T. F., Chemical Club, Victoria Hotel, Manchester, Secretary.
1905. Bixby, Willard G., 194, Hester Street, New York City, U.S.A., Blacking Manufacturer.
1905. Bjerregaard, August P., c/o Emil Calman & Co., Long Island City, N.Y., U.S.A., Varnish Chemist.
1904. Black, J. Wyelif, 20, Mardale Crescent, Edinburgh, Analytical Chemist.
1902. Black, W. Geoffrey, The Limes, New Street, Braintree, Essex, Chemist.
1894. Blackmore, H. S., 906, South Ninth Avenue, Mount Vernon, N.Y., U.S.A., Chemist (Pure Aluminium and Chemical Company).
1899. Blackwell, G. G., 44-47, The Albany, Liverpool, Mineral and Metal Merchant.
1896. Blagden, Victor, 50-51, Lime Street, London, E.C., Chemical Merchant.
1883. Blagden, W. G., The Manor House, Harting, near Petersfield, Chemical Merchant.
1897. Blair, Andrew A., 406, Locust Street, Philadelphia, Pa., U.S.A., Analytical Chemist.
1884. Blake, Jas., Thames Sugar Refinery, Silvertown, E., Manager.
1902. Blakemore, Geo. H., Great Cobar Copper Mining Syndicate, Lithgow, N.S.W., Australia, Metallurgist.
1890. Blakey, A. J., Dudbridge Mills, Stroud, Gloucestershire, Dyer.
1904. Bleakley, Wm., Dean's Mill, Swinton, Lancs., Cotton Mill Manager.
1893. Blears, John, c/o Langworthy Bros. and Co., Ltd., Greengate Mills, Salford, Dyer and Calico Printer.
O.M. Bles, A. J. S., 32, Chorlton Street, Manchester, Chemical Merchant.
1905. Bliss, H. J. W., c/o The Thames Varnish Co., Island Wharf, Rainham, Essex, Chemist.
1889. Bloede, Victor G., Station D., Baltimore, Md., U.S.A., Manufacturing Chemist.
1891. Bloomer, Fred. J., Penpont, Clydach, R.S.O., Glamorgan, Nickel Works Manager.
1886. Blount, Bertram, Laboratory, 76 and 78, York Street, Westminster, S.W., Analytical Chemist.
1888. Bloxam, A. G., 105, Birkbeck Bank Chambers, Holborn, W.C., Chemist and Patent Agent.
1890. Bloxam, W. Popplewell, Clothworkers Research Laboratory, The University, Leeds, Research Chemist.
1903. Blumenthal, Lionel, The Lindens, Stanley Road, Broughton Park, Manchester, Chemist.
1886. Blundstone, E. R., 77, York Street, Westminster, S.W., and (Journals) Heathfield, Park Road, Hampton Hill, Middlesex, Consulting Chemist.
1906. Blyth, M. Wynter, 36, Eastcheap, London, E.C., Analytical and Consulting Chemist.
1905. Blyth, Thomas R., Uphall Chemical Works, Ilford, Essex, Analytical Chemist.
O.M. Boake, A., Warton Road, Stratford, E., Manufacturing Chemist.
1888. Boake, Edmund J., Aberffraw, Nursery Road, Loughton, Essex, Manufacturing Chemist.
1899. Boehm, Fred., 16, Jewry Street, London, E.C., Chemical Agent and Merchant.
1898. Bogert, Prof. Marston T., Department of Organic Chemistry, Columbia University, New York City, U.S.A., Instructor in Organic Chemistry.
1903. Boissevain, Chas. E. H., 92, van Eeghenstraat, Amsterdam, Holland, Chemical Manufacturer.
1903. Bolam, Dr. H. W., 2, Summerfield, Leith, N.B. Lecturer on Chemistry.
1901. Bolton, E. Richards, 16, Flanchford Road, Ravenscourt Park, W., Manufacturing Chemist.
1905. Bond, John, Crowlands, Southport, Engineer.
1905. Bond, Josiah, Patagonia, Arizona, U.S.A., Mining Engineer.
1905. Bone, Dr. W. A., F.R.S., West House, Lidgett Park Road, Roundhay, Leeds, Lecturer in Chemistry and Metallurgy.
1892. Bookman, Dr. S., 9, East 62nd Street, New York City, U.S.A., Chemist.
1888. Boor, Leonard G., 21, Mincing Lane, London, E.C., Chemical Merchant.
1896. Boot, John C., Klatten, Java, Netherlands Indies, Chemist.
1904. Booth, N. Parr, Laboratory, Cadbury Bros., Ltd., Bournville, near Birmingham, Chemist.
1894. Booth, Robt., 110, Cannon Street, London, E.C., Engineer.
1891. Boothby, Chas., (Journals) 10, Church Row, Limehouse, E., and 70, Bedford Court Mansions, Bedford Square, London, W.C., Chemist.
1903. Boral, Robin, Rhodes Mount, Rhodes, near Manchester, Works Manager.
1897. Borland, C. R., P.O. Box 683, Concord, Mass., U.S.A., Smokeless Powder Manufacturer.

O.M. Berland, W. D., Beacon Lodge, Bean, via Dartford, Kent, Manufacturer of Explosives.

1903. Bernett, S., 19, St. Dunstan's Hill, London, E.C., Technical Chemist.

1903. Berosohek, Dr. L., 24, West 82nd Street, New York City, U.S.A., Chemist.

1903. Bossi, Dr. Arnold L., Arnold Print Works, North Adams, Mass., U.S.A., Assistant Manager.

1890. Bost, W. D. Ashton, Cartvale Chemical Works, Paisley, N.B., Chemical Manufacturer.

O.M. Bothamley, C. H., Tanglewood, Southside, Weston-super-Mare, Somerset, County Director of Technical Instruction.

1890. Bott, Dr. W. Norman, 16, St. Helen's Place, London, E.C., Consulting Chemist.

1884. Böttinger, Dr. H. T., Elberfeld, Germany; and (subs.) c/o The Bayer Co., Ltd., 19, St. Dunstan's Hill, E.C., Colour Manufacturer.

O.M. Bottle, Alex., 4, Godwyne Road, Dover, Pharmaceutical Chemist.

1901. Bottomley, Dr. J. Frank., c/o The Thermal Syndicate, Ltd., Neptune Road, Wallsend-on-Tyne, Consulting Chemist.

1906. Bottomley, W., c/o The United Alkali Co., Ltd., Fleetwood Salt Works, Fleetwood, Engineer.

O.M. Boulton, H. E., 64, Cannon Street, London, E.C., Chemical Manufacturer.

1890. Boulton, James, Crayford, Mills, Stratford, E., Manufacturing Chemist.

O.M. Boulton, Sir Samuel B., Bart., 64, Cannon Street, London, E.C., Chemical Manufacturer.

1883. Boulton, T. S., 14, Freegrove Road, Caledonian Road, N., Manager.

1900. Bourcoud, Augustin E., Comp. General de Productos Quimicos del Abofio, Gijón, Spain, Civil Engineer.

1905. Bourne, Lyman M., 119, Montague Street, Brooklyn, N.Y., U.S.A., Chemist.

1906. Boutwell, Arthur T., c/o Smith & Dove Manufacturing Co., Andover, Mass., U.S.A., Bleacher and Dyer.

1884. Bow, R. H., 7, South Gray Street, Edinburgh, Civil Engineer.

1904. Bowden, Thos., Durn Lea, Todmorden Road, Littleborough, Lancs., Dyer and Chemist.

1905. Bowen, Henry, c/o St. Louis Chemical Co., St. Louis, Mich., U.S.A., Secretary.

1906. Bowen, Ralph A., c/o National Aniline & Chemical Co., 36, Purchase Street, Boston, Mass., U.S.A.

1885. Bowen, S. B., Brickfield Chemical Works, Llanelly, South Wales, Chemical Manufacturer.

1899. Bowen, Wm., R.R.I., Fowler (Rural Route), Fresno Co., Cal., U.S.A., Chemist.

1888. Bower, Frank, Brewery House, Spitalfields, E., Analytical Chemist.

1897. Bower, Wm. H., 29th Street and Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemical Manufacturer.

1892. Bowes, Harry, Staveley, Broomfield Road, Heaton Moor, Stockport, Analytical Chemist.

1903. Bowey, John, jun., 567, Dufferin Avenue, London, Ont., Canada, Chemist.

1889. Bowing, Jno., 101, North Street, Wandsworth, S.W., Consulting Chemist.

1883. Bowley, Jos. John, Wellington Works, Battersea Bridge, and (Journals) 64, Redcliffe Gardens, London, S.W., Chemical Manufacturer.

1899. Bowley, J. Plunkett, 1, Wellington Road, Battersea, and (Journals) 64, Redcliffe Gardens, London, S.W., Varnish Manufacturer.

1883. Bowman, Dr. F. H., 4, Albert Square, Manchester, Chemical Manufacturer.

1894. Bowman, Jas. H., Canada Chemical Manufacturing Co., London, Ont., Canada, Chemist.

1894. Bowman, R., c/o Bowman's Ltd., Lythgoe's Lane, Warrington, Chemical Manufacturer.

1907. Bowman, Richard S., Sea View Terrace, Seaton Carew, Co. Durham, Chemist.

1898. Bowman, William, 29, Cortlandt Street, New York City, U.S.A., Chemist.

1904. Boyce, Frances E., near Fire Brigade Station, Fort, Bombay, India, Technical Chemist.

1893. Boyes, Frank, c/o Goodall, Backhouse, and Co., White Horse Street, Leeds, Technical Chemist.

O.M. Boyd, W., P.O. Box 212, Germiston, Transvaal, Technical Chemist.

1899. Boyes, Herb. J., 7, Alameda Barao de Piracicaba, Sao Paulo, Brazil, Chemist.

1905. Brabrook, G. Hale, Box 333, Taunton, Mass., U.S.A., Manufacturer.

1906. Bracegirdle, Harold W., 1 Mytton Street, Hulme, Manchester, Chemist.

1885. Bradburn, J. A., 311, Montgomery Street, Syracuse, N.Y., U.S.A., Manufacturing Chemist.

1883. Bradbury, A., Queen Buildings, 11, Dale Street, Liverpool, Chemical Broker.

1902. Bradbury, S., Fernoliffe, Milton Grove, Glebelands Road, Ashton-on-Mersey, Chemist.

1895. Bradford, Henry, c/o A. H. Carey, Goodwood, near Chichester, Analytical Chemist.

1896. Bragg, Everett B., 1838, Chicago Avenue, Evanston, Ill., U.S.A., Manufacturing Chemist.

1891. Braithwaite, Isaac, Holly Croft, Kendal, Westmoreland, Drysalter.

1897. Braithwaite, Jno. O., Holme Lacey, Warren Road, Chingford, Essex, Pharmaceutical Research Chemist.

1904. Braman, Winfred W., Box 353, State College, Pennsylvania, U.S.A., Assistant Instructor.

1903. Brame, J. S. S., 5, Coleraine Road, Blackheath, S.E., Demonstrator in Chemistry.

O.M. Bramham, W., 86, Bow Road, London, E., and (communications) 115, Broadhurst Gardens, West Hampstead, N.W., Chemical Engineer.

O.M. Bramwell, G. H., Cowley Hill, St. Helens, Lancashire, Alkali Manufacturer.

1904. Brandeis, R., Oesterreichischer Verein f. Chem. und Metall. Production, Aussig, Austria, Chemical Manufacturer.

1906. Brandt, H. O., 66, Sackville Street, Manchester, Merchant.

1902. Branegan, Jas. Aug., 555, North 16th Street, Philadelphia, Pa., U.S.A., Chemical Salesman.

O.M. Branson, F. W., Wynneholme, Far Headingley, Leeds, Pharmaceutical Chemist.

1903. Brassard, Fred. A., 46, Vicar Lane, Bradford, Yorks, Aniline Dyestuff Importer.

1901. Brearley, Harry, Salamander Stahlwerke, Jaegel, Riga, Russia, Analytical Chemist.

1906. Breckenridge, John E., American Agricultural Chemical Co., Carteret, N.J., U.S.A., Chemist.

1888. Breffitt, Wm., Glasshoughton, Castleford, Yorks., Glass Manufacturer.

1905. Brettell-Vaughan, E., 15, Queen Street, London, E.C., Storage Battery Analyst.

1901. Brewer, Dr. C. E., Wake Forest, N.C., U.S.A., Professor of Chemistry.

1900. Brewis, E. T., 31, Belgrave Road, Leyton, E., Chemist.

1894. Breyer, Theodor, 842, Lunt Avenue, Rogers Park, Chicago, Ill., U.S.A., Chemist.

1885. Briant, L., 24, Holborn Viaduct, London, E.C., Analytical Chemist.

1890. Brierley, J. T., Highfield, Golden Hill, Leyland, near Preston, Lancs., Analytical Chemist.

1894. Briggs, J. Burnett, Vauxhall Soap Works, 4, Blackstock Street, Liverpool, Soap Manufacturer.

1893. Briggs, J. F., 2, Frankfort Road, Herne Hill, S.E., Technical Chemist.

1885. Briggs, T. Lynton, 188, Central Avenue, Flushing, Long Island, N.Y., U.S.A., Technical Chemist.

1890. Brindley, G. F., 3, Itchome, Ushiwatsu Cho, Kojimachi-Ku, Tokio, Japan, Chemical Engineer.

1905. Bristol, Dr. H. Stanley, 74, Pinckney Street, Boston, Mass., U.S.A., Chemist.

1886. Bristow, G. W., c/o Walter J. Crook, 20, Billiter Lane, London, E.C., Chemical Manager.

1887. Broadbent, H., c/o Goodall, Backhouse, and Co., Sovereign Street, Leeds, Chemist.

1898. Broadhurst, W. Hanson, 393, Lafayette Avenue, Brooklyn, N.Y., U.S.A., Chemist.

1899. Brook, Arthur, Firework Factory, Sutton, Surrey, Firework Manufacturer.
O.M. Brook, J., Gwern-Tyno, Colwyn Bay, North Wales, Chairman of United Alkali Co., Ltd.
1905. Broemmel, G. M., 2501, California Street, San Francisco, Cal., U.S.A., Chemist.
1896. Brooke, C. B., jun., Colne House, Brantham, near Manningtree, Xylonite Manufacturer.
1900. Brooke, Jno. R., Government Laboratory, Singapore, S.S., Chemist.
1894. Brookes, E. A., c/o The Chilian Mills Co., Ltd., Chiguayante, Concepcion, Chile, Chemist.
1895. Brookman, Fred W., 6, West Street, Rochdale, Manure Works Manager.
1906. Brooks, Cecil J., c/o The Borneo Co., Ltd., Kuching, Sarawak, Metallurgist.
1903. Brooks, H. Kibbe, Claremont, N.H., U.S.A., Chemist.
1907. Broome, James S., 18, Seedley Park Road, Pendleton, Manchester, Science Lecturer.
1901. Broome, Jos., 5, Webster Terrace, Roselle Park, N.J., U.S.A., Chemical Engineer.
O.M. Brotherton, E. A., M.P., Commercial Buildings, Leeds, Ammonia Distiller.
1884. Brown, Prof. A. Crum, F.R.S., 8, Belgrave Crescent, Edinburgh, Professor of Chemistry.
1905. Brown, Prof. Adrian J., West Heath House, Northfield, near Birmingham, Professor of Brewing.
1902. Brown, A. H. M., 133, Kent Street, London, Ont., Canada, Metallurgist.
1891. Brown, Cæsar R., 23, Gower Road, Forest Gate, E., Works Foreman.
O.M. Brown, D., 93, Abbey Hill, Edinburgh, Chemical Manufacturer.
O.M. Brown, D., Donaghmore, Tyrone, Ireland, Soap Manufacturer.
1890. Brown, Edw. Hilton, c/o W. Ropes and Co., St. Petersburg, Russia, Analytical Chemist.
1903. Brown, Frank C., P.O. Box 211, Framingham, Mass., U.S.A., Foreman.
1904. Brown, Dr. Fred. W., 470, Lenox Avenue, New York City, U.S.A., Chemist.
1894. Brown, Geo. E., c/o "The British Journal of Photography," 24, Wellington Street, Strand, London, W.C., Chemist.
1905. Brown, Harold G. S., c/o Messrs. G. H. Ogston and Moore, Strada degle Argentieri, 19, Messina, Sicily, Analyst.
1900. Brown, Harry F., c/o E. I. du Pont Co., 716, Market Street, Wilmington, Del., U.S.A., Chemist.
1905. Brown, Hawthorne J., Oak Villa, Elton, Bury, Lancs., Paper Maker.
O.M. Brown, Henry, Benskin's Brewery, Watford, Herts., Brewing Chemist.
1899. Brown, Dr. Henry C., The Chemical Works, King's Lynn, Chemical Manufacturer.
O.M. Brown, Dr. Horace T., F.R.S., 52, Nevern Square Kensington, S.W, Brewing Chemist.
1905. Brown, Hugh B., c/o Jas. Robertson & Sons, Ltd., Thrushgrove Works, Paisley, Chemist.
O.M. Brown, Dr. J. Campbell, 8, Abercromby Square, Liverpool, Professor of Chemistry.
1891. Brown, J. Henry, Minas d'Aljustrel, Alemtejo, Portugal, Technical Chemist.
1901. Brown, Jos., Ashleigh House, Savile Town, Dewsbury, Manufacturing Chemist.
1905. Brown, Nicol, 4, The Grove, Highgate, N., Mining, Director.
1906. Brown, Percy S., c/o Western Electric Co., West and Bethune Streets, New York City, U.S.A., Chemist.
1892. Brown, Reginald B., c/o Badische Co., Ltd., 2, Samuel Ogden Street, Manchester, Technical Chemist.
1889. Brown, Robt., The Firs, Hartford, Northwich, Engineer.
1901. Brown, Samuel B., Ruthven, Bowden Lane, Marple, Cheshire, Calico Printer.
O.M. Brown, Walter, c/o Jas. H. Dennis and Co., Ltd., Widnes, Technical Chemist.
1900. Brown, Walter R., Victor Chemical Works, 89, Board of Trade Buildings, Chicago, Ill., U.S.A., Chemist and General Superintendent.
1901. Browne, Dr. Arthur L., 213, Courtland Street, Baltimore, Md., U.S.A., Analytical Chemist.
1906. Browne-Cave, E. J. C., "Strathallan," Bootle, Liverpool, Works Chemist.
1905. Browning, Prof. K. C., Medical College, Colombo, Ceylon, Professor of Chemistry.
O.M. Browning, W., Broad Oak, Accrington, Calico Printer.
1901. Brownlie, David, Cordale Works, Renton, Dumbartonshire, Chemist.
1902. Brownrigg, Marcus P., Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Analytical Chemist.
1902. Brownsdon, Dr. H. W., King's Norton Metal Co., Ltd., Abbey Wood, Kent, Works Chemist.
1902. Bruce, Alex., Laboratory, Hyde Park Corner, Colombo, Ceylon, Chemist.
1890. Bruce, Jas., Craik, Saskatchewan, Canada, Distiller.
1900. Bruce, Wm. T., c/o Hugh Wallace and Co., Ltd., 5, Fenchurch Street, London, E.C., Director.
1892. Bruckmann, G. T., 192, 18th Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
1905. Bruinier, A. G., 534, Canal Street, New York City, U.S.A., Agent for Kalle and Co.,
O.M. Brunner, H., Holly Mount, Tarbock Road, Huyton, near Liverpool, Chemical Manufacturer.
1894. Brunner, H. Bertram, Winnington Park, Northwich, Chemist and Electrician.
1887. Brunner, J. F. L., M.P., c/o Brunner, Mond and Co., Ltd., 39, Victoria Street, London, S.W., Chemical Manufacturer.
O.M. Brunner, Sir J. T., Bart., M.P., Druid's Cross, Wavertree, Liverpool, Chemical Manufacturer.
1902. Brunner, Roscoe, The Winnington Hall Club, Winnington, Northwich, Alkali Manufacturer.
1905. Brunt, R. A., Box 71, Windsor, Ont., Canada, Sugar Chemist.
1894. Brunton, J. Dixon, Wire Mill, Musselburgh, N.B., Wire Manufacturer.
1904. Bryant, Arthur P., c/o Clinton Sugar Refining Co., Clinton, Iowa, U.S.A., Chemist.
1903. Bryant, V. Seymour, 80, Beeches Road, West Bromwich, Analytical Chemist.
1905. Bryce, Clarence H., c/o Benj. Moore and Co., 244, Water Street, Brooklyn, N.Y., U.S.A., Factory Superintendent.
1894. Bryce, Thos., Tharsis Mines, Huelva, Spain, Chemist.
1897. Bryson, Jas., Pumpherston Oil Works, Midcalder, N.B., Oil Works Manager.
1892. Buchanan, D. G., (Subs.) 40, St. Vincent Place, Glasgow, and (Journals) c/o Gibbs and Co., Iquique, Chili, Analyst.
1904. Buchanan, E. F., 80, Byers Avenue, Akron, Ohio, U.S.A., Chemist.
1888. Buchanan, Jas., jun., Caledonia Foundry, Brasenose Road, Liverpool, Engineer.
1904. Buchanan, J. L., 3, The Wiend, Lower Bebington, Cheshire, Analytical Chemist.
1904. Buchanan, Joshua D., c/o Nobel's Explosives Co., Ltd., Polmont Station, N.B., Chemist.
1897. Buck, Chas. A., 521, Locust Street, South Bethlehem, Pa., U.S.A., Chief Chemist (Bethlehem Iron Co.).
1906. Buckie, Robert H., 82, Sydenham Road, London, S.E., Works Chemist.
1897. Bucknill, Jno. A., P.O. Box 52, Government Patent Office, Pretoria, Transvaal, Comptroller General.
1900. Bull, Dr. Benjamin S., 104, Humber Road, Blackheath, S.E., Technical Chemist.
1902. Bull, Irving C., P.O. Box, 294, Middletown, N.Y., U.S.A., Chemist.
1899. Bult, Herbert J., 18, Billiter Street, London, E.C Chemist.
1907 Bult, Stanley R., 18, Billiter Street, London, E.C Chemist.
O.M. Bamby, H., Coltness Ironworks, Newmains, N.B., Ironworks Manager.

O.M. Bunker, H. E., 19, Napier Street, Toronto, Ont., Canada, Technical Chemist.
1901. Bunting, Henry H., c/o Peruvian Corporation, Ltd., Lima, Peru, Analyst.
1894. Bunting, W. Lightfoot, Forest Bank, Crawshawbooth, near Manchester, Calico Printer.
1905. Bunzl, Hugo, 175, High Street, Chorlton-on-Medlock, Manchester, Chemist.
1893. Burbridge, Jas., India-rubber Mills, Tottenham, N., India-rubber Manufacturer.
1886. Burdekin, G., jun., 10, Clifton Terrace, St. Helens, Lancashire, Chemical Works Manager.
1896. Burford, Samuel F., Beechworth, Stoneygate Road, Leicester, Analytical Chemist.
1889. Bürger, Dr. J., 1, Birch Avenue, Talbot Road, Old Trafford, Manchester, Technical Chemist.
1901. Burgess, Prof. C. F., University of Wisconsin, Madison, Wis., U.S.A., Electro-chemical Engineer.
1889. Burgess, Geo., Hale Road, Ditton, Widnes, Chemist.
1889. Burgess, Wm. T., 20, Priory Road, Bedford Park, London, W., Analytical Chemist.
1902. Burkard, Dr. Ernst, The Heyden Chemical Works, Garfield, N.J., U.S.A., Chemist.
1889. Burkhardt, Dr. G. A., c/o Bohrgesellschaft Erkelenz, Erkelenz, Rheinland, Germany, Chemist.
1897. Burland, Lt.-Col. Jeffrey H., 824, Sherbrooke Street, Montreal, Canada, Paper and Card Manufacturer.
1900. Burleigh, Wm. F., c/o Murphy Varnish Co., Newark, N.J., U.S.A., Technical Chemist.
1897. Burls, Frank B., 4, Dyer's Hall Road, Leytonstone, Essex, Chemist.
1898. Burls, Herbert T., (Journals) c/o Royal Societies Club, St. James Street, S.W., and (communications) Foulis Terrace, Onslow Gardens, S.W., Mechanical Engineer.
1901. Burnand, Sydney, Manbré Saccharine Co., Ltd, Hammersmith, W., Manager.
O.M. Burnard, R., Plymouth Chemical Works, Plymouth, Chemical Manufacturer.
1891. Burnet, Henry K., North Brook Vitriol Works, Bradford, Yorks., Sulphuric Acid Maker.
1897. Burnet, Jno. Jas., 18, University Avenue, Glasgow, Architect.
1907. Burnham, Frank E., c/o Avery Chemical Co., 7, Sears Street, Boston, Mass., U.S.A., Chemist.
1893. Burnham, J. C., Cordite Factory, Aruvankad, Nilgiri Hills, India, Analytical Chemist.
1900. Burnside, Chas. F., California Powder Works, Santa Cruz, Cal., U.S.A., Chemist.
1900. Burr, Edmund C., 1722, Vallejo Street, San Francisco, Cal., U.S.A., Manufacturer.
O.M. Burrell, B. A., 8, Springfield Mount, Leeds, Analytical Chemist.
1906. Burrough, Ernest J., Cale Street Distillery, Chelsea, S.W., Rectifier.
1892. Burrough, Horace, jun., 509, West Lombard Street, Baltimore, Md., U.S.A., Technical Chemist.
1888. Burrows, Edw., Home Villa, Low Fell, Gateshead-on-Tyne, Alkali Works Manager
1907. Burt, Dr. Milo C., c/o Taylor, Burt & Co., Holyoke, Mass., U.S.A.
1905. Burtenshaw, Wm. H., P.O. Box 814, Detroit, Mich., U.S.A., Secretary, Michigan Carbon Works.
1901. Burton, Alf., 44, York Street, Toronto, Canada, Dyer and Finisher.
1905. Burton, Jas. K., 336, Drexel Building, Philadelphia, Pa., U.S.A., Consulting Chemist.
1903. Burton, Jno., 2, Green Street, Bethnal Green, E., Dye and Chemical Manufacturer.
1904. Burton, T. R., c/o Scott, Greenwood and Son, 19, Ludgate Hill, London, E.C., Technical Journalist.
1892. Burton, Wm., The Hollies, Clifton Junction, near Manchester, Potter's Chemist.
1897. Burwell, A. W., Kyle Street, Lakewood, *via* Cleveland, Ohio, U.S.A., Consulting Chemist.
1895. Bury, J. H., Church Chemical Works, near Accrington, Chemical Manufacturer.
1906. Busby, Fred. E., Arnold Print Works, North Adams, Mass., U.S.A., Chemist.
1897. Bush, J. M., c/o W. J. Bush and Co., Ltd., Ash Grove, Hackney, E., Manufacturing Chemist.
1897. Butler, David B., 41, Old Queen Street, Westminster, S.W., Cement Expert.
1903. Butler, Fredk., Ash Tree Lane, Hough Green, near Widnes, Manager (Ditton Copper Works).
1890. Butler, Paul, Lowell, Mass., U.S.A., Ammunition Manufacturer.
1885. Butler, Samuel, The Cedars, Compton, Wolverhampton, Brewer.
1905. Butler, T. H., c/o Frau Wensel, Forstweg 14, Jena, Germany, Chemical Student.
1886. Butler, W. W., c/o Mitchells & Butlers, Ltd., The Brewery Library, Cape Hill, Birmingham, Brewer.
1903. Buttenshaw, E. L., Thurleigh, Priory Road, Gale, Cheshire, Analytical Chemist.
O.M. Butterfield, J. C., 79, Endlesham Road, Balham, S.W., Analytical Chemist.
1892. Butterfield, W. J. A., 66, Victoria Street, Westminster, S.W., Analytical Chemist.
1897. Butters, Charles, 28–31, Bishopsgate Street Within, London, E.C., and (Journals) Rosalawn, Berkeley, Cal., U.S.A., Metallurgist.
1900. Butterworth, Elwell R., c/o Reversible Collar Co., 111, Putnam Avenue, Cambridge, Mass., U.S.A., Chemist.
1902. Butterworth, F. J., P.O. Box 54, Newark, N.J., U.S.A., Chemist.
1892. Buttfield, Horace V., 13, Wellington Road, Bush Hill Park, Enfield, N., Chemical Demonstrator.
O.M. Byard, A. G., c/o Burt, Boulton, and Haywood, Apartado, 8, Bilbao, Spain, Technical Chemist.
1905. Byrne, F. A., 2, Ludgate Hill, Birmingham, Director of Chemical Co.
1899. Byrnes, Dr. Eugene A., 918, F. Street, N.W., Washington, D.C., U.S.A., Patent Lawyer.
1893. Byrom, T. H., Laboratory, Wigan Coal and Iron Co., Wigan, Analytical Chemist.
1887. Bythway, M., 44, Lloyd Street, Albert Square, Manchester, Drysalter.

C

1884. Cabot, Godfrey L., 82, Water Street, Boston, Mass., U.S.A., Chemist.
1906. Caddick, Arthur, 9, Albert Crescent, Lincoln, Works Chemist.
1889. Cadett, Jas., Ashtead, Surrey, Chemical Engineer.
1902. Cady, Wm. H., 127, Power Street, Providence, R.I., U.S.A., Colour Chemist.
1905. Cain, Dr. J. C., 28, Pembury Road, Lower Clapton, N.E., Colour Chemist.
1891. Caines, G. S. A., 7, Rochester Terrace, Camden Road, London, N.W., Analytical Chemist.
1897. Cairns, Wm., 5, Carlton Place, Glasgow, Plumber.
1891. Caldecott, W. Arthur, Box 1167, Johannesburg, Transvaal, South Africa, Metallurgist.
1905. Calder, Prof. Edwin E., Long Meadow, R.I., U.S.A., Professor of Chemistry.
1897. Calder, W. A. S., Ormidale, Little Moor Hill, Smethwick, Chemical Manufacturer.
1888. Caldwell, Wm., Murray Street, Paisley, N.B., Drysalter.
1891. Calkin, Wm. S., Spring Forge, Pa., U.S.A., Paper Pulp Works Chemist.
1902. Calm, Chas. E., 190, Michigan Street, Chicago, Ill., U.S.A., Manufacturing Chemist.
1904. Calvert, Dr. Harry T., West Riding of Yorkshire Rivers Board, Wakefield, Chemist.
1901. Calvert, Jos. E., 293, Butler Street, Etna, Allegheny Co., Pa., U.S.A., Analytical Chemist.
1895. Cambier, Jacob, 910, Spruce Street, Pueblo, Colo., U.S.A., Chemist.
1894. Cameron, Alex., Whitcher Place, Rochester Road, Camden Road, N.W., Chemical Engineer.
1891. Cameron, Jas., 70, Old Chester Road, Woodside, Rock Ferry, Cheshire, Chemist.
1904. Cameron, Walter S., 220, West 146th Street, New York City, U.S.A., Manufacturing Perfumer.

O.M. Cammack, J., 67, King Edward Road, Denton's Green, St. Helens, Lancashire, Technical Chemist.

1886. Campbell, Andrew, c/o Burmah Oil Co., Ltd., Dunneedaw, Rangoon, Burmah, Analytical Chemist.

O.M. Campbell, Archibald, Berry Lodge, Rugeley, Staffordshire, Technical Chemist.

1902. Campbell, Ashley, Colonial Sugar Refining Co., Ltd., Yarraville Refinery, Melbourne, Vic., Australia, Analytical Chemist.

1906. Campbell, Geo. H., 15, Spadina Road, Toronto, Canada, Manufacturing Chemist.

1899. Campbell, Jas. Eunyce, 22, Cambridge Street, Worcester, Mass., U.S.A., Chemical Engineer.

1904. Campbell, J. H., 41, Summit Street, Brooklyn, N.Y., U.S.A., Chemist.

1901. Campbell, Kenneth F., M.Inst.C.E., 1, Peel Street, Huddersfield, Civil Engineer.

1904. Campion, A., Laboratory, 144, Wellington Street, Glasgow, Chemist and Metallurgist.

1897. Canfield, F. D., jun., c/o Cuban Sugar Refining Co., Cardenas, Cuba, Sugar Refiner.

1893. Cannon, J. C., Staverton House, Shoreham, Sussex, Analyst

O.M. Cannon, M., 25, Stormont Road, Clapham Common, S.W., Vinegar Works Manager.

1891. Canziani, Enrico, 3, Palace Green, Kensington, W., Civil Engineer.

1891. Carden, Albert J., Dunster House, 12, Mark Lane, E.C., Distiller.

1904. Carel, Prof. Hubert C., Laboratory, University of Minnesota, Minneapolis, Minn., U.S.A., Chemist, (State Board of Health).

1893. Carey, Arthur, The Groves, Grassendale Park, near Liverpool, Chemist.

O.M. Carey, Eustace, The United Alkali Co., Ltd., 30, James Street, Liverpool; and (Journals) The Groves, Grassendale Park, near Liverpool, Chemical Manufacturer.

1906. Carey, William G., Moulton Settlement, Lyman Mission, City Road, London., E.C., Chemist.

1904. Cargill, J. T., c/o Finlay, Fleming and Co., Rangoon, Burmah, East India Merchant.

O.M. Carlile, T., St. Bryde's, Dunblane, N.B., Chemical Manufacturer.

1895. Carlsson, Hugo, Fagersta, Sweden, Analytical Chemist.

1893. Carmichael, Dr. H., 176, Federal Street, Boston, Mass., U.S.A., Analytical Chemist.

1896. Carmichael, Herbert, Bureau of Mines, Victoria, British Columbia, Public Analyst and Assayer.

1884. Carmody, Prof. Patrick, Government Laboratory, Port of Spain, Trinidad, Analytical Chemist.

1903. Carneiro da Cunha, J. M., Comp. Agricola and Mercantil, Rua do Apollo, 28, Pernambuco, Brazil, Manager.

1897. Carnell, Wm. C., c/o Tacony Chemical Works, Bridesburg, Philadelphia, Pa., U.S.A., Chemist.

O.M. Caro, Dr. H., C. 8 N. 9, Mannheim, Baden, Germany, Technical Chemist.

1906. Caro, Dr. Nikodem, Meinekestrasse 20, Berlin, Germany, Analytical Chemist.

1893. Carpenter, C. C., South Metropolitan Gas Co., 709A, Old Kent Road, London, S.E., Civil Engineer.

1900. Carpenter, Frank B., 11, South 12th Street, Richmond, Va., U.S.A., Chemist.

1900. Carpenter, Harry B., c/o Lister's Agricultural Chemical Works, Newark, N.J., U.S.A.

1903. Carpenter, H. C. Harold, 11, Oak Road, Withington, Manchester, Chemist and Metallurgist.

1906. Carpenter, P. H., Cawnpore Sugar Works, Cawnpore, India, Analyst.

O.M. Carpenter, R. Forbes, Prestwich, Greencroft Gardens, West Hampstead, N.W., Chief Inspector under the Alkali, &c., Works Acts.

1904. Carr, Francis H., Kelvin, Church Avenue, Sidcup, and (Journals), Burroughes, Wellcome and Co., Ltd., Dartford, Kent, Manufacturing Chemist.

1904. Carroll, Jas. L., 23, Division Place, Newark, N.J., U.S.A., Secretary (American Oil and Supply Co.).

1886. Carruthers, J. G., Burnbrae House, Milngavie, N.B., Dyeworks Manager.

1901. Carson, Geo. C., Hotel Broadway, Denver, Colo., U.S.A., Mining Engineer.

1906. Cart, John Trevor, c/o Messrs. C. A. Parsons and Co., Heaton Works, Newcastle-on-Tyne, Chemist.

O.M. Carteighe, M., 180, New Bond Street, London, W., Pharmaceutical Chemist.

1904. Carter, A., Cuba Street, Petone, Wellington, New Zealand, Works Manager.

1905. Carter, Robert A., c/o Roessler and Hasslacher Chemical Co., Box 68, South Amboy, N.J., U.S.A., Chemist.

1895. Carter, Stewart F., Glenlyon Dyeworks, Sayleville, R.I., U.S.A., Superintending Chemist.

1903. Carter, Thomas, 322, Scarr Hill, Bradford, Yorks, Works Chemist.

1886. Carter, W. Chas., c/o Dominion Iron and Steel Co., Sydney, C.B., Canada, Analytical Chemist.

1889. Carulla, F. J. R., 84, Rose Hill Street, Derby, Chemical Manufacturer.

1906. Carveth, Dr. H. R., Niagara Electrochemical Co., Niagara Falls, N.Y., U.S.A., Works Manager.

1906. Casaburi, Dr. V., c/o Ford Morocco Co., Wilmington, Del., U.S.A., Leather Chemist.

1903. Caspari, Dr. W. A., 28, Coleshill Road, Teddington, Chemist and Physicist.

1895. Catlin, Chas. A., 133, Hope Street, Providence, R.I., U.S.A., Chemist (Rumford Chemical Works).

1896. Caven, Robt. M., University College, Nottingham, Lecturer in Chemistry.

O.M. Cawley, G., 25, Victoria Street, Westminster, S.W., Chemical Engineer.

O.M. Cawley, J., 278, Passaic Street, Newark, N.J., U.S.A., Analytical Chemist.

1897. Cawley, Thos. A., British Gelatin Works, New Bedford Road, Luton, Gelatin Manufacturer.

1900. Cayvan, Llewellyn L., 927, West Monroe Street, Chicago, Ill., U.S.A., Chemist.

1902. Cerasoli, Alburto, c/o Dr. L. Mond, 18, Avenue Rd., Regent's Park, N.W., Engineer.

1906. Chadsey, S. B., c/o International Harvester Co., Hamilton, Ontario, Canada, Chemist.

1891. Chadwick, Walter M., 24, West 3rd Street, Bayonne, N.J., U.S.A., Chemical Works Manager.

1894. Chaloner, G. W., 26, Eagle Wharf Road, Hoxton, N., Chemical Manager.

1901. Chamberlain, G. E., 103, South Kensington Avenue, La Grange, Ill., U.S.A., Chemist.

1902. Champion, Edmund C., 510, South Washington Avenue, Iola, Kansas, U.S.A., Chemist.

O.M. Chance, A. M., Chemical Works, Oldbury, near Birmingham, Chemical Manufacturer.

O.M. Chandler, Dr. C. F., Columbia University, West 116th Street, New York City, U.S.A., Professor of Chemistry.

1893. Chaplin, Dr. Edw. M., Public Analyst's Laboratory, Wakefield, Yorks., Analytical Chemist.

1906. Chaplin, Wm. H., 13, Penywern Road, Earl's Court, London, S.W., Wine Merchant.

1890. Chapman, Alf. C., 8, Duke Street, Aldgate, E.C., Analytical Chemist.

1906. Chapman, Arthur J., Baronsmere, Stanhope Avenue, Church End, Finchley, N., Analytical Chemist.

1905. Chapman, D. L., 10, Parsonage Road, Withington, Manchester, Demonstrator in Chemistry.

1906. Chapman, E. A., 2, Kensington Park, Stapleton Road, Bristol, Works Chemist.

1903. Chapman, Geo. W., Swift Fertilizer Works, 913 Prudential Building, Atlanta, Ga., U.S.A., Superintendent.

O.M. Chapman, Spencer, 36, Mark Lane, E.C., Chemical Manufacturer.

1894. Charlier, A. C. J., 6, Talbot Road, South Tottenham, N., Consulting Chemist.

1902. Charlton, Thos., 252, Irvington Place, Denver, Colo., U.S.A., Manufacturing Chemist.

1900. Chase, March F., c/o Mineral Point Zinc Co., Depue, Ill., U.S.A., Chemist.

1902. Chase, R. L., Arnold Printworks, North Adams, Mass., U.S.A., Manager.
1896. Chattock, Herbert E., 73, Apsley Road, Clifton, Bristol, Oilcake Manufacturer.
1905. Cheeseman, Frank P., 100, William Street, New York City, U.S.A., Paint Manufacturer.
1901. Cheetham, Howard, 18, St. Ann Street, Manchester, Chartered Patent Agent.
1905. Cheke, Thos. W., 105, London Road, Sawbridgeworth, Analytical Chemist.
1894. Cheney, J. P., c/o Cheney Bros., South Manchester, Conn., U.S.A., Silk Manufacturer's Chemist.
1885. Cheyne, A. M., c/o Messrs. Burgoyne, 16, Coleman Street, London, E.C., Analytical Chemist.
1905. Chick, Oliver, 52, High Street, Hornsey, N., Analytical Chemist.
1902. Chilwell, John, Post Office, Auckland, New Zealand, Analyst.
1906. Chittenden, George, The Francis Frost Co., Ltd., Toronto, Canada, Chemist.
1893. Cholerton, A. F., 40½, Belgrave Gate, Leicester, Manufacturing Chemist.
1890. Chorley, Jno. C., Bewsey, Oxford Road, Birkdale, Lancs., Analytical Chemist.
O.M. Christie, J., Levenfield, Alexandria, N.B., Dyer and Printer.
1903. Christie, John, c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Analytical Chemist.
1906. Christie, Dr. W. A. K., Technical Chemist.
1898. Christison, Geo., Cremona, Cambridge Drive, Glasgow, Engineer.
O.M. Chrystal, W. J., 7, West George Street, Glasgow, Chemical Manufacturer.
1904. Chubb, H. M., Wharfedale Villas, Tadcaster, Yorks., Brewery Chemist.
O.M. Church, Professor A. H., F.R.S., Shelsley, Kew, Surrey, Professor of Chemistry in the Royal Academy.
1890. Church, Elihu D., jun., 63, Wall Street, New York City, U.S.A., Soda Manufacturer.
1906. Church, Sumner R., c/o Barrett Manufacturing Co., 17, Battery Place, New York City, U.S.A., Chemical Engineer.
1896. Claflin, Alan A., (Communications) Box 1189, Boston; and (Journals) Littleton, Mass., U.S.A., Manufacturing Chemist.
1900. Clamer, Guilliam H., 46, Richmond Street, Philadelphia, Pa., U.S.A., Chemist.
1885. Clanahan, H. C., 79, Mosley Street, Manchester, Chemical Merchant.
1901. Clapham, Henry E., Laurel Bank, Wilsden, near Bradford, Yorks., Technical Chemist.
1905. Clapp, Geo. A., 503, Walnut Street, Newtonville, Mass., U.S.A., Chemist.
1891. Clapp, Ralph R., c/o Standard Ammonia Co., Ltd., Iceland Wharf, Old Ford, E., Ammonia Works Manager.
1889. Clapperton, J., jun., Analytical Chemist.
1903. Clare, Henry, Hepscott, Morpeth, Northumberland, Schoolmaster.
1905. Clark, Alfred N., Box 168, Wallaceburg, Ont., Canada, Technical Chemist and Engineer.
1906. Clark, Allan J., c/o Homestake Mining Co., Lead, S. Dakota, U.S.A., Metallurgist.
1904. Clark, Arthur W., c/o Johnson and Johnson, New Brunswick, N.J., U.S.A., Chemist and Bacteriologist.
1896. Clark, Donald, Bairnsdale, Victoria, Australia, Director of School of Mines.
1904. Clark, Ernest, Royal Technical Institute, Salford, Assistant Lecturer in Chemistry.
1904. Clark, Prof. Friend E., Central University of Kentucky, Danville, Ky., U.S.A., Professor of Chemistry.
1904. Clark, Dr. Homer, c/o The Vacuum Varnish and Chemical Co., 6, Seaview Avenue, East Norwalk, Conn., U.S.A., Chemical Manufacturer.
O.M. Clark, Dr. J., 138, Bath Street, Glasgow, Analytical
1900. Clark, Jno., Broadway Works, Millwall Docks, London, E., Manufacturing Chemist.
1906. Clark, M. H., c/o Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.
1902. Clark, Robt. M., Rockbank, Partickhill, Glasgow, Chemist.
1906. Clark, T. W. Firth, Laboratory, Johnson Street, Mile End, London, E., Analyst.
1906. Clark, Wm. B., 42, Robertson Street, Greenock, Chemist.
1907. Clark, Wm. H., 152, Newport Road, Middlesbrough, Analytical Chemist.
1903. Clark, Dr. W. Inglis, 104, South Canongate, Edinburgh, Manufacturing Chemist.
1902. Clark, Wm. Linus, Champion Coated Paper Co., Hamilton, Ohio, U.S.A., Chemist.
1904. Clarke, A. R., 613–617, Eastern Avenue, Toronto, Canada, Leather Manufacturer.
1891. Clarke, Goddard, M.P., South Lodge, Champion Hill, S.E.; and (Journals) 60—64, Artillery Lane, London, E., Drysalter.
1903. Clarke, Robt. W., (Journals) c/o Clinical Research Association, Ltd., 1, Southwark Street, London, S.E., (subs.) 3, Aberdeen Villas, Chase Road, Southgate, N., Analyst.
1897. Clarke, Wm. B., c/o Edison-Swan U.E.L. Co., Ltd., Ponders End, N., Electro-Chemist.
O.M. Claudet, A. C., 6, Coleman Street, E.C.; and (Journals) 9, Daleham Gardens, Hampstead, N.W., Metallurgist.
1889. Claus, Wm. H., c/o Claus and Ree, Clayton, Manchester, Manufacturing Chemist.
O.M. Clayton, E. G., Chemical Laboratory, 23, Holborn Viaduct, London, E.C., Consulting Chemist.
1895. Clayton, Dr. G. C., Etonfield, Wavertree, Liverpool.
1891. Clayton, J. W., c/o Clayton and Jowett, Ltd., Concert Street, Liverpool, Essence Distiller.
1894. Clayton, Robt. H., Woodleigh, Blackfield Lane, Kersal, Manchester, Chemist.
1905. Clayton, W. E., Royal Victoria Yard, Deptford, S.E., Superintendent.
1907. Clement, Leonard, 13, Champion Park, Denmark Hill, London, S.E., Chemist.
1893. Clemes, J. H., The Bracken, Newquay, Cornwall.
1886. Cleminshaw, E., Alkali Works, Oldbury, near Birmingham, Technical Chemist.
1883. Clemons, G. H., Cudbear Street, Hunslet Road, Leeds, Dyeware Manufacturer.
1884. Clerk, Dugald, 18, Southampton Buildings, Chancery Lane, W.C., Engineer.
1899. Cleveland, D. B., 1403, First National Bank Building, Cincinnati, Ohio, U.S.A., Chemist.
1905. Clexton, Thos. J., 285, Congress Street, Boston, Mass., U.S.A., Manager (A. Klipstein & Co.).
1906. Clifford, Jos., Ivy House, Prestbury, near Macclesfield, Chemist.
1900. Clifford, Wm., Sewage Outfall Works, Wolverhampton, Sewage Works Manager.
O.M. Cloud, T. C., 4, Lloyd's Avenue, Fenchurch Street, London, E.C., Metallurgist.
O.M. Clowes, Dr. F., 40, Craven Street, Charing Cross, W.C.; and the Grange, College Road, Dulwich, S.E., Chief Chemist (L.C.C.).
1891. Clutton, J. H., Elliott's Metal Co., Ltd., Burry Port, R.S.O., Carmarthenshire, Assayer.
1900. Clymer, Wm. R., c/o National Carbon Co., Cleveland, Ohio, U.S.A., Chemist.
1899. Coates, Chas. E., jun., Louisiana State University, Baton Rouge, La., U.S.A., Professor of Chemistry.
1888. Coats, Jno. T., 105, Broughton Street, Edinburgh, Manufacturing Chemist.
1893. Cobb, Jno. W., Farnley Ironworks, near Leeds, Technical Assistant to Managing Director.
1904. Coblentz, Lambert, 1708, Sutter Street, San Francisco, Cal., U.S.A., Chemist.
1894. Coblentz, Dr. Virgil, College of Pharmacy, 115, West 68th Street, New York City, U.S.A., Professor of Chemistry.
1899. Cochran, Alfred, 559, Madison Street, Brooklyn, N.Y., U.S.A.

1898. Cochrane, A. Lynde, 9, Charles Street, Boston, Mass., U.S.A., Clerk (Cochrane Chemical Co.).
1901. Cockburn, John A., Ardeer, Stevenston, Ayrshire, Analytical Chemist.
1902. Cocking, Allan T., Carhampton House, Four Oaks, Sutton Coldfield, Ammunition Manufacturer.
1905. Coes, Chas. S., 119, East River Street, Hyde Park, Mass., U.S.A., Oil Chemist.
1906. Coffman, Herbert, 314, East Seneca Street, Ithaca, N.Y., U.S.A., Cement Works Chemist.
1903. Cofman-Nicoresti, J., 24, St. Gabriel's Road, Cricklewood, N.W., Chemist.
1903. Coggeshall, Dr. G. W., Chestnut Street, Dedham, Mass., U.S.A., Chemical Manufacturer.
1887. Coghill, P. de G., Borax Works, Old Swan, Liverpool, Technical Chemist.
1884. Cogswell, W. B., Syracuse, N.Y., U.S.A., Chemical Engineer.
O.M. Cohen, Dr. J., 13, Cardigan Road, Leeds, Analytical Chemist.
1897. Cohn, Alfred J., 122, East 74th Street, New York City, U.S.A., Chemist.
1901. Cohn, Sigmund, 13, Dutch Street, New York City, U.S.A., Metallurgical Chemist.
1904. Cohoe, Prof. W. P., 110, Park Road, Toronto, Canada, Professor of Chemistry.
1903. Colbert, W., British S.A. Dynamite Factory, Modderfontein, Transvaal, Analytical Chemist.
1891. Colby, Albert L., 217, West 110th Street, New York City, U.S.A., Metallurgical Engineer.
1899. Colby, E. A., Baker Platinum Works, Newark, N.J., U.S.A., Metallurgical Chemist.
O.M. Colby, W. H., Carreg-wen, Aberystwith, Wales.
1893. Coleman, W. H., 78, Egerton Road, Withington, Manchester, Tar Works Chemist.
O.M. Collens, E., Vinegar Works, Stourport, Worcestershire, Manager.
1905. Collett, John H., Hillfield, Gloucester, Chemical Manufacturer.
1887. Collett, J. M., Hillfield, Gloucester, Chemical Manufacturer.
1901. Colley, Bernard T., c/o Velardena M. and S. Co., Velardena, Durango, Mexico, Assayer.
1903. Collier, Pierre, Companhia Industrial Pernambucana, Pernambuco, Brazil, Civil Engineer.
1893. Collin, Dr. C. A., Ferguslie Threadworks, Paisley, N.B., Textile Chemist.
1898. Collingridge, Frank, 73, Fountain Road, Edgbaston, Birmingham, Chemist.
1883. Collins, J. H., Crinnis, Par Station, Cornwall, Technical Chemist.
1899. Collins, S. Hoare, Armstrong College, Newcastle-on-Tyne, Agricultural Chemist.
1888. Collins, W. Hepworth, c/o Edw. Wihl & Co., 17, Nicholas Street, Manchester, Analytical Chemist.
1899. Collis, Walter T., 89, Greenfield Road, Harborne, Birmingham, Chemist.
1891. Colman, Dr. H. G., Elmside, Worcester Park, Surrey, Analytical Chemist.
1892. Colquhoun, Lewis, c/o South African Explosives Co., Modderfontein, Transvaal, Analytical Chemist.
1894. Colquhoun, W., Plas Penyddol, Bersham, near Wrexham, North Wales, Engineer.
1901. Colwell, J. Kear, Finsbury Town Hall, Rosebery Avenue, E.C., Analytical and Consulting Chemist.
1906. Comber, A. W., Suramangalam, Salem District, South India, Manager (Magnesite Works).
1900. Comey, Arthur M., 12, Pearl Street, Boston, Mass., U.S.A., Technical Chemist.
1906. Compton, Miss N. J., Library, University of Nebraska, Lincoln, Neb., U.S.A., Librarian.
1899. Conant, Francis M., Megansett, Mass., U.S.A., Chemical Engineer.
1906. Condit, Louis C., Chemical Laboratory, B. and O. R. R., Mount Clare, Baltimore, Md., U.S.A., Chemist.
1901. Connah, Jas., 12, Kiddepore Gardens, Hampstead, N.W., Government Analyst.
1906. Conner, Arthur R., 1070, Fort St. West, Detroit, Mich., U.S.A., Chemist.
1883. Connor, C. C., 4, Queen's Elms, Belfast, Ireland, Chemist.
1891. Conradson, Pontus H., Galena Oil Works, Franklin, Pa., U.S.A., Analytical Chemist.
1906. Conrau, Oliver, Sugar Estate "La Grange," St. Croix, Danish West Indies, Administrator.
1889. Conroy, Dr. Jas. T., Adirondack, Grassendale Park, Liverpool, Chemist.
1887. Constable, W. H., (Journals) Australian Alum Works, Runcorn; and (communications) Riversdale, Dee Banks, Chester, Analytical Chemist.
1902. Converse, W. A., Rooms 226—224, Postal Telegraph Building, Chicago, Ill., U.S.A., Chemist.
O.M. Cook, H. J., The Firs, Woodford Green, Essex, Soap Manufacturer.
1903. Cook, Jas. W., London and Provincial Dye Works, Hackney Wick, N.E., Dyer.
1888. Cook, Jno. J., Atlas Foundry, St. Helens, Lancashire, Ironfounder.
1898. Cook, Thos. Alex., East London Soap Works, Bow, E., Soapmaker.
1899. Cook, Walter G., 9, Hendon Lane, Finchley, N., Analytical Chemist.
1891. Cooke, Arthur W., c/o Brotherton and Co., Ltd., Holmes Street, Dewsbury Road, Leeds, Analytical Chemist.
1904. Cooke, W. Ternent, The University, Adelaide, South Australia, Lecturer in Chemistry.
1901. Cooper, T. S., 36, Demesne Road, Alexandra Park, Manchester, Calico Printing Chemist.
1891. Cooper, Walter J., The Elms, Lower Penarth, South Wales, Cement Works Manager.
1906. Cooper, William, Public Analyst's Laboratory, 67, Surrey Street, Sheffield, Analytical Chemist.
1897. Cooper, Wm. R., 113, Tulse Hill, S.W., Electrical Engineer.
1890. Corcoran, Bryan, 31, Mark Lane, London, E.C., Chemical Engineer.
1887. Cordner-James, J. H., Finsbury House, Blomfield Street, London, E.C., Mining Engineer.
1905. Cormack, Wm., c/o G. Nelson, Dale and Co., Ltd., Emscote Mills, Warwick, Chemist.
1899. Cornelison, Dr. Robt. W., Bloomfield, N.J., U.S.A., Consulting Chemist.
1906. Cornwell, R. de Vere, Salisbury, Rhodesia, Chemist.
1903. Corrêa de Brito, Dr. L., Rua do Commercio, 6, Recife, Pernambuco, Brazil, Civil Engineer.
1889. Corrie, David, c/o Nobel's Explosives Co., Ltd., Polmont Station, N.B., Technical Chemist.
1903. Cortright, R. M., 20, South Centre Street, Bethlehem, Pa., U.S.A., Assistant Chemist.
1894. Coste, J. H., 40, Craven Street, W.C., and (Journals) 54, Alconbury Road, Upper Clapton, N.E., Analytical Chemist.
1891. Cotton, W. F., Hollywood Roebuck, Co. Dublin, Gas Works Manager.
1905. Cotton, Wm. H., 16, Hauptstrasse, Höchst a/Main, Germany, Chemist.
1906. Coupe, Miles, 46, Millarbarn Lane, Waterfoot, near Manchester, Chemist.
1898. Coupe-Annable, H. W., c/o Tungsten and Rare Metals Co., Queen's Road, Battersea, S.W., Chemist.
1894. Court, Heywood, 67, Surrey Street, Sheffield, Analytical Chemist.
1898. Courtney, Samuel, 37, The Mount, Belfast, Ireland, Manager.
1894. Cousins, W. J., 17, Temple Chambers, Temple Avenue, E.C., Consulting Chemist and Director.
1906. Cowan, George D., Bridge House, Bridge Road, Millwall, E., Manager, Desilverising Works.
1903. Cowan, Wallace, 6, Salisbury Road, Edinburgh, Analytical Chemist.
1893. Cowan, W. J., 12, Park Avenue, Wood Green, N., Fine Colour Manufacturer.
1897. Cowburn, Arthur W., 29, Princess Street, Manchester, Chemical Merchant and Analytical Chemist.
1904. Cowee, Harvey D., 161, River Street, Troy, N.Y., U.S.A., Chemist.

1905. Cowles, Horace W., jun., Box 225, Hinsdale, Du Page Co., Ill., U.S.A., Assistant Chemist.
1891. Cowsley, A. J., 225, Barry Road, Dulwich, S.E., Analytical Chemist.
1891. Cowper-Coles, Sherard Osborn, Grosvenor Mansions, Victoria Street, Westminster, S.W., Metallurgical Engineer.
1905. Cox, Harold N., 398, McDonough Street, Brooklyn, N.Y., U.S.A., Chemist.
1902. Coyle, Benj. C., City Laboratory, 17, Castle Street, Dublin, Analytical Chemist.
1884. Craig, Geo., Chemical Laboratory, 95, Bath Street, Glasgow, Technical Chemist.
1895. Craig, Thos. J., Cathkin View, Clincarthill, Rutherglen, N.B., Chemist.
1904. Cramer, A., jun., 882, East 29th Street, Paterson, N.J., U.S.A., Chemist.
1901. Crane, Fred. D., 28, Hillside Avenue, Montclair, N.J., U.S.A., Consulting Chemist.
1902. Crane, Jasper E., c/o The Arlington Co., Arlington, N.J., U.S.A., Chemist.
1898. Cranfield, Wm., 11, Avondale Place, Halifax, Yorks., Teacher of Chemistry.
1903. Cranmer, Ridgeway, 170, 88th Street, Bay Ridge, Brooklyn, N.Y., U.S.A., Chemist.
1902. Craven, Alfd. B., 91, Fielding Terrace, Armley, Leeds, Analytical Chemist.
1889. Craven, Chas. E., Oak Villa, Bramley, near Leeds, Dyer.
1899. Craven, Jas, c/o Columbia Creosoting Co., Shirley, Ind., U.S.A., Chemist.
1906. Craven, J. A., 119, Town Street, Armley, Leeds, Chemist.
1891. Craven, Jno., jun., c/o Dominion Tar and Chemical Co., Ltd., Sydney, C.B., Canada, Chemist.
1906. Craven, John L., P. O. Box 3568, Boston, Mass., U.S.A., Chemist and Salesman.
1885. Craw, John, 15, Cadogan Street, Glasgow, Drysalter.
O.M. Crawford, D., Langdale's Chemical Manure Co., Ltd., St. Lawrence, Newcastle-on-Tyne, Manager.
1890. Crawshaw, E., 25, Tollington Park, London, N., Dye Merchant.
1900. Crayen, Dr. Gustav, 354, West 23rd Street, New York City, U.S.A.
1905. Crean, Jno. F., 25, Abercromby Square, Liverpool, Oil Refiner.
O.M. Cresswell, C. G., Ermyngarth, Ashtead, Surrey; and 9, Bridge Street, Westminster, S.W., Chemist.
1901. Cribb, Cecil, 136, Shaftesbury Avenue, London, W., Analytical and Consulting Chemist.
1905. Crighton, W. H., 138, Evering Road, Stoke Newington, N., Chemist.
1890. Criper, Wm. R., c/o Messrs. D. Weldie and Co., Konnagar, near Calcutta, India, Manufacturing Chemist.
1902. Croasdale, Dr. Stuart, 1574, York Street, Denver, Colo., U.S.A., Mining Engineer and Metallurgist.
1889. Cronquist, Prof. A. Werner, Storksund, Stockholm, Sweden, Inspector General of Explosives.
1901. Cronquist, G. W., Hyllinge, Grufva, Sweden, Fire Brick Works Manager.
O.M. Crookes, Sir Wm., F.R.S., 7, Kensington Park Gardens, Notting Hill, W., Analytical Chemist.
1896. Crosby, Thos., Llanelly Steelworks, Llanelly, South Wales, Metallurgist.
O.M. Crosfield, A. L., 46, Bidston Road, Oxton, Birkenhead, (Journals) c/o Prof. B. Moore, Biochemical Dept., The University, Liverpool, Analytical Chemist and Assayer.
1896. Crosfield, Capt. G. R., Volunteer Quarters, Sankey Street, Warrington, Soap Manufacturer.
1884. Cross, C. F., 4, New Court, Lincoln's Inn, London, W.C., Analytical Chemist.
1894. Crossley, Prof. Arthur W., Pharmaceutical Society, 17, Bloomsbury Square, London, W.C., Professor of Chemistry.
1904. Crossley, T. Linsey, c/o Nashua River Paper Co., East Pepperell, Mass., U.S.A., Analytical Chemist.
1888. Crossman, Tom, Albion Brewery, Coldhurst Street,
1894. Crow, Henry W., 94, Romford Road, Stratford, E., Tar Distiller.
1894. Crow, Dr. J. K., 2, Ulundi Road, Blackheath, S.E., Technical Chemist.
1902. Crowell, Henry H., c/o Jos. Bancroft and Sons Co., Wilmington, Del., U.S.A., Dyer.
1893. Crowther, Edw., Woodland Dyeworks, Headingley, Leeds, Dyer.
1883. Crowther, Horace W., The Beeches, West Bromwich, Technical Chemist.
1899. Crowther, J., Tenuta Etrusca Miniere, Campiglia Marittima, Toscana, Italy, Metallurgist.
1906. Crowther, R. E., c/o Mark Fletcher and Sons, Ltd., Moss Lane, Whitefield, Manchester, Chemist.
1884. Crowther, Walter M., Chemical Works, Gomersal, near Leeds, Manufacturing Chemist.
1884. Crumbie, W. D., 146, Washington Street, East Orange, N.J., U.S.A., Analytical Chemist.
1906. Cruser, Dr. Fred. Van D., c/o Union Metallic Cartridge Co., Bridgeport, Conn., U.S.A., Chemical Engineer.
1902. Crush, E. H., 3, Westcombe Park Road, Blackheath, S.E., Technical Chemist.
1892. Cullen, Wm. Dynamite Factory, Modderfontein, Transvaal, Chemist.
1903. Cullen, W. H., The Castner-Kellner Alkali Co., Ltd., Wallsend-on-Tyne, Engineer.
1897. Culmann, Dr. Julius, c/o G. Siegle und Co., 79, Duane Street, New York City, U.S.A., Chemist and Colourist.
1905. Culver, Ralph F., 16, Quincy Street, North Adams, Mass., U.S.A., Chemist.
1883. Cuming, James, jun., Chemical Works, Yarraville, Melbourne, Australia, Chemical and Fertiliser Manufacturer.
1905. Cuming, R. Burns, Currie Street, Adelaide, South Australia, Manufacturing Chemist.
1897. Cunliffe, Albert J., Claytonfield, Clayton-le-Woods, Chorley, Lancashire, Calico Printer.
1907. Cunningham, James E., Minas Peña del Hierro, Provincia de Huelva, Spain, Analytical Chemist.
1906. Cunnington, Alfred V., c/o Brunner, Mond and Co., Ltd., Northwich, Cheshire, Chemical Works Manager.
O.M. Curphey, W. S., 7, Derby Crescent, Kelvinside, Glasgow, Alkali Works Inspector.
1902. Currier, Edw. Eug., 74, Fremont Avenue, Everett, Mass., U.S.A., Chemist.
1898. Curtis, Marvin, 103, Front Street, San Francisco, Cal., U.S.A., Wine Chemist.
1903. Cushing, Robt. P., c/o Kistler, Lesh & Co., Lock Haven, Pa., U.S.A., Chemist.
1902. Cutbush, Chas. G., 149, Westcombe Hill, Blackheath, S.E., Electrical Engineer.
1899. Cutler, Fred. F., 183, Essex Street, Boston, Mass., U.S.A., Publisher.
1904. Cutts, Henry E., 55, Fulton Street, New York City, U.S.A., Technical Chemist.

D

O.M. Dacie, J. C., Soap Works, Putney, S.W., Soap Manufacturer.
1906. Dains, F. B., Washburn College, Topeka, Kas., U.S.A., Professor of Chemistry.
1897. Dains, Herbert H., c/o J. E. Forpiaux, 2, Union Court, London, E.C., Analytical Chemist.
1905. Dalal, Vasanji Premji, Nepean Sea Road, Malabar Hill, Bombay, Lecturer on Chemistry.
1904. Dale, G., Waverley Terrace, Hood Lane, Warrington, Technical Chemist.
1907. Dalley, Henry, 9, East 69th Street, New York City, U.S.A., President.
1905. Dampney, Gerald F., Hunter's Hill, Sydney, N.S.W., Australia, Paint Manufacturer.
1884. Daniell, Louis C., (Journals) Royal Standard Brewery, Tamworth, New South Wales, and (subs.) c/o W. T. Allen and Co., [illegible]

1904. Danker, Dan. J., 247, Atlantic Avenue, Boston, Mass., U.S.A., Dyestuff and Chemical Manufacturer.
1905. Danker, Fred E., 73, Sawyer Avenue, Dorchester, Mass., U.S.A., Salesman (Oakes Manufacturing Co.).
1903. Dannenbaum, Dr. H., National Ammonia Co., Frankford, Philadelphia, Pa., U.S.A., Secretary and Treasurer.
1902. Danziger, Jos. L., 259, West 112th Street, New York City, U.S.A., Analytical Chemist.
1885. Darby, Jno. H., Brymbo Hall, near Wrexham, Ironmaster.
1894. Darling, G. A., P.O. Box 3720, Johannesburg, Transvaal, S.A., Metallurgical Chemist.
O.M. Darling, W. H., 26, Dover Street, Manchester, Analytical Chemist.
1887. Davenport, Dr. B. F., 161, Tremont Street, Boston, Mass., U.S.A., Consulting Chemist.
1900. Davidson, Alex., jun., 8, Traquair Park, Corstorphine, Midlothian, N.B., Analytical Chemist.
1899. Davidson, Charles, 328, Golfhill Drive, Dennistoun, Glasgow, Analytical Chemist.
1905. Davidson, Frank A., 182, Mount Vernon Street, West Roxbury, Mass., U.S.A., Pharm. Chemist.
1901. Davidson, G. M., Chicago and N.W. Railroad Shops, P.O. Station E., Chicago, Ill., U.S.A., Chemist.
1883. Davidson, J. E., 40, Percy Gardens, Tynemouth, Chemical Manufacturer.
1891. Davidson, Richard, 133, Victoria Road, Dundee, Oil Merchant's Clerk.
O.M. Davidson, R. Holden, c/o United Alkali Co., Ltd., Ammonia Soda Works, Fleetwood, Manager.
1904. Davidson, Robert, c/o Dalgety and Co., Ltd., 15, Bent Street, Sydney, N.S.W., Australia.
1905. Davidson, Thos. A., c/o Naylor Bros., Varnish Works, Southall, Middlesex, Chemist.
1905. Davidson, Dr. Wm. B., City Gas Works, Saltley, Birmingham, Chemist.
1889. Davies, G. W., 8, Spring Hill, Stockport, Chemical Lecturer.
1906. Davies, Harry R., 58, Hamilton Street, Readville, Mass., U.S.A., Chemist.
1898. Davies, Herbert E., The Laboratory, 28, Chapel Street, Liverpool, Analytical Chemist.
1907. Davies, James, 16, Suffolk Street, Rotherhithe, London, S.E., Scientific Apparatus Maker.
1896. Davies, Llewellyn J., 103, Bute Road, Cardiff, Analytical and Consulting Chemist.
1886. Davies, M. Lloyd, North American Chemical Co., Bay City, Mich., U.S.A., Alkali Works Manager.
1897. Davies, Saml. H., c/o Rowntree and Co., Ltd., Cocoa Works, York, Research Chemist.
1903. Davies, Thomas, 56, Wellesley Street, Toronto, Ont., Canada, Manufacturer.
1900. Davis, Arthur C., 2, Downing Grove, Cambridge, Cement Maker.
O.M. Davis, A. R., Fern Bank, Hawarden, Flintshire, Analytical Chemist.
1901. Davis, Bernard F., c/o Borneo Co., Bidi, Sarawak, Metallurgical Engineer.
1902. Davis, Charles B., c/o National Brewers' Academy, 402, West 23rd Street, New York City, U.S.A., Technical Chemist.
1902. Davis, Emerson, 30, Watson Street, Detroit, Mich., U.S.A., Chemist.
1893. Davis, Fred., 51, Imperial Buildings, Ludgate Circus, London, E.C., Consulting Chemist.
O.M. Davis, George E., 265, Strand, London, W.C., Chemical Engineer.
O.M. Davis, H. W., Government Laboratory, Clement's Inn Passage, Strand, W.C., Analytical Chemist.
1906. Davis, V. P., c/o American Sheet and Tin Plate Co., Vandergrift, Pa., U.S.A., Chemist.
1897. Davis, Wm. A., 8, Quenington Mansions, Rostrevor Road, Fulham, S.W., Chemist.
1903. Davison, Alex. Young, 219, Pleasant Street, Winthrop, Mass., U.S.A., Dyestuff and Chemical Merchant.
1900. Daw, Fred W., Alexander Place, Ebbw Vale, Mon. Metallurgical Chemist.
1903. Dawes, Arthur W., 3, Madison Place, Albany N.Y., U.S.A., Chemist.
O.M. Dawson, C. A., 40, Russell Road, Sefton Park Liverpool, Technical Chemist.
1886. Dawson, W. Haywood, British Alizarin Co., Ltd. Silvertown, E., and (Journals) 187, Eglinto Road, Woolwich, S.E., Technical Chemist.
1901. Day, Dr. David T., U.S. Geological Survey, Wash ington, D.C., U.S.A., Geologist.
O.M. Deacon, H. Wade, 8, Ullet Road, Liverpool; an (Journals) c/o F. W. Wright, 22, Peel Hous Lane, Widnes, Alkali Manufacturer.
O.M. Deakin, H. T., Dewhurst, Egerton, near Bolton Dyer.
1903. Dean, Harry, 23, Spinkfield Road, Birkby, Hudders field, Chemist.
1906. Dean, Harry, Armstrong College, Newcastle-on Tyne, Demonstrator.
1899. Deane, Leopold M., 5, Whitehall Road, Rugby Explosives Chemist.
1905. Dearman, E., c/o The Lavers Manufacturing Co. Ltd., Woolwich, N.S.W., Australia, Tar Dis tiller.
1892. Deaville, B., Beech Avenue, Nottingham, Manu facturing Chemist.
1903. De Blois, W. H., c/o General Chemical Co., Hudso Heights, N.J., U.S.A., Chemist.
1899. De Castro, J. Paul, Laboratory, Effingham House Arundel Street, Strand, W.C., Consulting Chemis and Assayer.
1902. De Cow, J. A., 14, Sun Life Building, Montreal Canada, Chemist.
1893. De Clerck, Maurice, Heule-lez-Courtrai, Belgium.
1884. Deering, W. H., Chemical Department, Roya Arsenal, Woolwich, S.E., Analytical Chemist.
1900. Deerr, Noel, Blairmont, Berbice, British Guiana Analytical Chemist.
1902. Deghuée, Dr. Jos. A., 247, Harrison Street, Brook lyn, N.Y., U.S.A., Chemist.
1901. De Jonge, Cornelius, 36, Doughty Street, Brooklyn N.Y., U.S.A., Pharmaceutical Chemist.
1893. Delahaye, Philibert, 105, Rue St. Lazare, Paris (IX.) Gas Engineer.
1901. Delany, Chas., c/o Elliott Bros., Ltd., O'Connel Street, Sydney, N.S.W., Australia, Chemist.
1888. Dempsey, Geo. C., 165, Market Street, Lowell Mass., U.S.A., Chemist.
1904. Dempwolf, Chas., jun., 713, South George Street York, Pa., U.S.A., Chemical Manufacturer.
1899. Denham, Wm. S., 2, Kelvinside Terrace North Glasgow, Chemist.
1891. Denison, Joseph R., Lingholme, Heaton, Bradford Yorks., Analytical Chemist.
1898. Dent, Dr. Frankland, Government Analyst' Laboratory, Singapore, S.S., Consulting Chemist
1905. Derby, Wallace G., c/o Nichols Copper Co., Laure Hill, New York City, U.S.A., Assayer.
1901. Devas, Dr. Ernest W., Fairview, Hale Grove Edgware, N.W., Technical Chemist.
1906. Deverell, Louis C., c/o Straits Trading Co., Ltd. Singapore, S.S., Chief Chemist.
1898. Dewar, Alex. H., c/o The Linoleum Manufacturing Co., Staines, Middlesex, Chemist.
O.M. Dewar, Sir J., F.R.S., Royal Institution, Albemarl Street, W. (Journals); and 1, Scroope Terrace Cambridge, Professor of Chemistry and Physics
1889. Dewey, Fred. P., Lanier Heights, Washington, D.C. U.S.A., Metallurgist.
1904. Dewhirst, J. A., Borough Laboratory, Halifax Yorks., Analyst.
1891. De Wilde, Prof. P., 1, Quai du Léman, Geneva, Switzerland, Professor of Chemistry.
1903. Diamond, Wm., c/o Simon-Carves, Ltd., Barnes Collieries, near Barnsley, Yorks., Works Manager.
O.M. Dibdin, W. J., Edinburgh Mansions, Howick Place S.W.; and (Journals) Purley Bury, Purley Downs Road, Sanderstead, Surrey, Analytical Chemist.

1897. Dick, Jno., c/o Jno. Dick, Ltd., 77, York Street, Toronto, Ont., Canada, Manufacturer.
1902. Dick, Jno., Wharf Road, Cubitt Town, London, E., Manager and Chemist.
1904. Dick, W. D., c/o Hugh Baird and Sons, 29, St. Vincent Street, Glasgow, Analytical Chemist.
1896. Dickenson, F. M., c/o Broken Hill Proprietary Co., 3, Great Winchester Street, E.C., Secretary.
1904. Dickenson-Gair, C. J., 55, Lyham Road, Brixton, S.W., Analytical Chemist.
1902. Dickerman, Prof. Judson C., University of Wisconsin, Madison, Wis., U.S.A., Professor of Chemistry.
1893. Dickerson, E. N., 141, Broadway, New York City, U.S.A., Lawyer.
O.M. Dickinson, A. J., 57, Lewisham High Road, New Cross, S.E., Tar Distiller.
1906. Dickinson, Cyril, Abbotsford, Hollycroft Avenue, Hampstead, N.W., Analytical Chemist.
1898. Dickson, Samuel, 2, Broadway, Westminster, S.W., Analytical Chemist.
1899. Dieckmann, Dr. Otto, 1182, Harrison Avenue, Cincinnati, Ohio, U.S.A., Chemist.
1901. Diehl, Oscar C., c/o Saginaw Salt Co., St. Charles, Mich., U.S.A., Chemist.
1894. Diestel, Wm., 128, Duane Street, New York City, U.S.A., Dyestuff Importer.
1906. Dillon, Fred N., 16, Prospect Street, Fitchburg, Mass., U.S.A., Engineer.
1898. Dillon, Wm., Highfield, Wetherby, Yorks, Oil, Colour, and Varnish Manufacturer.
O.M. Divers, Dr. E., F.R.S., 3, Canning Place, Palace Gate, Kensington, W., Professor of Chemistry.
1903. Divine, Robt. E., c/o W. E. Garrigues, Foot of Leib Street, Detroit, Mich., U.S.A., Chemist.
1899. Dixon, Fred W., 557, West 144th Street, New York City, U.S.A., Dyer.
1888. Dixon, Prof. Harold B., F.R.S., Owens College, Manchester, Professor of Chemistry.
1884. Dixon, Wm., 102, Spring Street, Bury, Lancashire, Science Master.
1902. Dixon, Wm. A., 97, Pitt Street, Sydney, N.S.W., Australia, Public Analyst and Assayer.
1892. Dobb, Thos., c/o J. T. Dobb & Son, West Bar, Sheffield, Pharmaceutical Chemist.
O.M. Dobbie, Dr. J. J., F.R.S., Royal Scottish Museum, Chambers Street, Edinburgh, Director.
1901. Dobbie, Jas., Laurel Bank, Broomfield Road, Ayr, N.B., Tanner.
O.M. Dobbin, Dr. L., Chemical Laboratory, University, Edinburgh, Professor of Chemistry.
1906. Dobson, Samuel, 22, Dangan Road, Cambridge Park, Wanstead, N.E., Paint Works Manager.
1890. Dodd, A. J., Heathfield House, Belvedere, Kent, Works Manager.
1889. Dodd, W. Ralph, Trederwen, Village Road, Enfield, Middlesex, Chemical Works Manager.
1906. Dodds, Thos., c/o Reckitt & Sons, Ltd., and (Journals) 3, Morrill Street, Holderness Road, Hull, Works Manager and Chemist.
1900. Dodge, Dr. Francis D., 291, Henry Street, Brooklyn, N.Y., U.S.A., Chemist.
1907. Dodge, Frank E., 6951, Hegeman Street, Tacony, Pa., U.S.A., Chemist.
1906. Dodsworth, Walter A., Journal of Commerce, 32, Broadway, New York City, U.S.A., Editor.
1897. Doerflinger, Wm. F., c/o Acker Process Co., Niagara Falls, N.Y., U.S.A., Research Chemist.
1897. Dohme, Dr. Alf. R. L., Messrs. Sharp and Dohme, Baltimore, Md., U.S.A., Manufacturing Chemist.
1905. Dolan, H., Dunesk, Grappenhall Road, Stockton Heath, Warrington, Chemist.
1903. Dole, Richard B., c/o U.S. Geological Survey, Washington, D.C., U.S.A., Chemist.
1897. Dolge, Carl B., Westport, Conn., U.S.A., Manufacturer of Instruments and Antiseptics.
1902. Donald, Dr. Jas. T., 112, St. Francois Xavier Street, Montreal, Canada, Consulting Chemist.
1906. Donald, Richard A., 80, King Street East, Toronto, Canada, Wood Distiller.
[illegible] Donald, W., Saltcoats, N.B., Analytical Chemist.
1900. Donald, Wm., Ridgefield Park, Bergen Co., N.J., U.S.A., Assayer and Chemist.
1902. Donaldson, Thos., c/o South African Explosives Co., Ltd., Modderfontein, Transvaal, Chemist.
1905. Donnan, Prof. F. G., Physico-Chemical Laboratory, The University, Liverpool, Professor of Physical Chemistry.
1886. Doolittle, Orrin S., c/o Semet Solvay Co., 160, William Street, New York City, U.S.A., Chemist.
1905. Doolittle, Roscoe E., 17, South 15th Street, Newark, N.J., U.S.A., Chemist.
1890. Dore, Jas., Copper Works, High Street, Bromley-by-Bow, E., Distiller's Engineer.
1896. Doremus, Dr. Chas. A., 55, West 53rd Street, New York City, U.S.A., Professor of Chemistry.
O.M. Dott, D. B., Ravenslea, Musselburgh, N.B., Analytical Chemist.
1906. Doty, Henry D., c/o Manhattan Rubber Manufacturing Co., Passaic, N.J., U.S.A., Chemist.
1897. Douglas, Geo., Heather Bank, Bingley, Yorks., Dyer.
1894. Douglas, Loudon M., 3, Lauder Road, Edinburgh, Chemical Manufacturer.
1884. Douglas, William, Diamond Plantation, Demerara, British Guiana, Chemical Engineer.
1900. Doulton, H. Lewis, Royal Doulton Potteries, Lambeth, S.E., Potter.
1900. Dow, Dr. Allan W., 73, Upper Mountain Avenue, Montclair, N.J., U.S.A., Chemist.
1898. Dow, Herbert H., Midland, Mich., U.S.A., Manufacturing Chemist.
1905. Dowbiggin, James, Craiglands, Albert Park, Lancaster, Chemist.
1885. Dowson, J. Emerson, 39, Victoria Street, Westminster, S.W., Civil Engineer.
1901. Doxrûd, Christian, Christiania, Norway, Professor of Chemical Technology.
1902. Drake, Bryant S., Barksdale, Wis., U.S.A., Chemist.
1885. Drake, Chas. A., Three Mills Distillery, Bromley-by-Bow, E., Brewer.
1886. Dreaper, W. P., 41, Quilter Road, Felixstowe, Suffolk, Technical Chemist.
O.M. Drew, D., Lower House Print Works, near Burnley, Calico Printer.
1906. Drew, W. Newton, Raincliffe, Eccleshield, near Sheffield, Chemical Manufacturer.
1896. Drewsen, Dr. Viggo B., 5, Beekman Street, New York City, U.S.A., Wood Pulp and Paper Expert.
O.M. Dreyfus, Dr. C., Clayton Aniline Co., Ltd., Clayton, Manchester, Dye Manufacturer.
1905. Dreyfus, Dr. Isaac, c/o Schoellkopf & Co., Perry and Mississippi Streets, Buffalo, N.Y., U.S.A., Chief Chemist.
1904. Dreyfus, Dr. L. A., c/o The Muralo Co., New Brighton, N.Y., U.S.A., Chemist.
1893. Dreyfus, S., 1, Sunnyside Terrace, North Road, Clayton, Manchester, Chemist.
1899. Dreyfus, Dr. Wm., 162, East 95th Street, New York City, U.S.A., Chemist.
1899. Drobegg, G., 81, Maiden Lane, New York City, U.S.A., Superintending Chemist.
1889. Drummond, Hon. Sir George, K.C.M.G., Montreal, Canada.
1898. Drummond, Dr. Isaac W., 436, West 22nd Street, New York City, U.S.A., Chemist.
1904. Dubois, Dr. Norman A., 22, Hawthorne Avenue, Yonkers, N.Y., U.S.A., Instructor in Chemistry.
1903. Dubuque, Edwin D., 310, Realty Building, Elmira, N.Y., U.S.A., Chemist.
1899. Ducas, B. P., 161, Front Street, New York City, U.S.A., Chemical and Dyestuff Importer.
1907. Ducca, Dr. Wilhelm, 315, Avenue C., Bayonne, N.J., U.S.A., Chemist.
1905. Duché, E., 6, Eastcheap, London, E.C., Merchant.
1897. Duckham, Alex., Phœnix Wharf, West Ferry Road, Millwall, E., Works Chemist.
1905. Duckworth, Harry S., Dover, N.H., U.S.A., Paper-works Chemist.
1899. Dudley, Dr. C. B., 1219, 12th Avenue, Altoona, Pa., U.S.A., Analytical Chemist.
1887. Dudley, Prof. W. L., Vanderbilt University, Nashville, Tenn., U.S.A., Professor of Chemistry.

1906. Duerr, E. Oliver, Alan Drive, Hale, Cheshire, Fruit Preserver.
1899. Duff, Wm. S., Sebert Villa, Bushwood, Leytonstone, Essex, Manufacturing Chemist.
1905. Duffus, W. B., Las Minas de Rio Tinto, Prov. de Huelva, Spain, Chemist.
1901. Dufty, Lawrence, 8, Clarke Street, Sheffield, Analytical Chemist.
1905. Duggan, Edw. J., The Charles E. Sholes Co., 164, Front Street, New York City, U.S.A., Vice-President.
O.M. Duggan, T. R., 60, Foyle Road, Blackheath, S.E., Analytical Chemist.
1898. Duisberg, Dr. Carl, The Bayer Co., Ltd., (Journals) Elberfeld, Germany; (subscriptions) 19, St. Dunstan's Hill, E.C., Chemist.
1905. Dukes, Bernhard, 1, Great James Street, Bedford Row, London, W.C., Patent Agent.
1888. Dukes, T. William, Box 10, Vryheid, South Africa, Merchant.
1906. Duncalfe, Roger, Forge Mills, Bestwood Colliery, Nottingham, Glue Manufacturer.
1889. Duncan, Arthur W., 1, Trafalgar Road, Higher Bentcliffe, Pendleton, Manchester, Analytical Chemist.
1904. Duncan, R. A., P.O. Box, 509, Honolulu, Hawaii, Chemist.
1904. Duncan, Wm. Wheeler, 406, Massachusetts Avenue, Boston, Mass., U.S.A., Chemist.
1906. Dunford, Jno. H., Trent Side Bone Works, Nottingham, Assistant Manager.
1898. Dunham, Edw. K., 338, East 26th Street, New York City, U.S.A., Professor of Bacteriology and Hygiene.
1905. Dunlop, Harry, Cragdarroch, Cove, Dumbartonshire, Chemist.
1892. Dunn, Fred., 193, Collins Street, Melbourne, Victoria, Australia, Analytical Chemist.
O.M. Dunn, Dr. J. T., 10, Dean Street, Newcastle-on-Tyne, Consulting Chemist.
O.M. Dunn, P., Northern Assurance Buildings, Albert Square, Manchester, Chemical Merchant.
1901. Dunsford, Geo., Laboratory, Wigan Coal and Iron Co., Ltd., Wigan, Analytical Chemist.
Q.M. Dupré, Dr. A., F.R.S., Edinburgh Mansions, Howick Place, S.W., Consulting Chemist.
1905. Durand, Halsey, Dept. of Health, 55th Street and 6th Avenue, New York City, U.S.A., Chemist.
1897. Durant, H. T., P. O. Box 603, Buluwayo, Matabeleland, South Africa, Metallurgist.
1905. Durfee, Winthrop C., 190, High Street, Boston, Mass., U.S.A., Manufacturing Chemist.
1897. Durkee, Frank W., Tuft's College, Medford, Mass., U.S.A., Assistant Professor of Chemistry.
1907. Durrans, Thos. H., 1, Cornwall Terrace, Regent's Park, London, N.W., Chemist.
1899. Duryea, Chester B., c/o Edwardsburg Starch Co., Cardinal, Ont., Canada, Starch Manufacturer.
1906. Dushman, Saul, School of Practical Science, Toronto, Canada, Electrochemist.
1891. Dvorkovitz, Dr. P., 45, St. Mary Axe, London, E.C., Technical Chemist.
1903. Dyck, George E., c/o Virginia Carolina Chemical Co., Station C., Memphis, Tenn., U.S.A., Analytical Chemist.
O.M. Dyer, Dr. B., 17, Great Tower Street, London, E.C., Analytical and Consulting Chemist.
O.M. Dyson, C. E., Flint, North Wales.
1902. Dyson, George W., 89, Cowlishaw Road, Sheffield, Analyst.
1892. Dyson, Septimus, 8, Belmont Avenue, Harrogate, Manufacturing Chemist.

E

1905. Eager, Chas. E., 124, High Street, Boston, Mass., U.S.A., Merchant.
1904. Eames, Charles J., 99, Water Street, New York City, U.S.A., Consulting Chemist.
1899. Earnshaw, Edward H., c/o The Union Gas and Electric Co., 4th and Plum Streets, Cincinnati, Ohio, U.S.A., Chemist.
O.M. Earp, W. R., c/o Rowland A. Earp, Buckfastleigh, Devon, Chemical Manufacturer.
1902. Easterbrooks, Frank D., Raritan Copper Works, Perth Amboy, N.J., U.S.A., Chemist.
1884. Eastick, C. E., 7, King Edward Street, Whitechapel, E., Sugar Works Manager.
O.M. Eastick, J. J., 2, St. Dunstan's Hill, London, E.C., Analytical and Consulting Chemist.
1890. Eastlake, A. W., Grosmont, Palace Road, Streatham Hill, S.W., Petroleum Works Manager.
1905. Easton, Herbert Fyfe, Herodsfoot, St. Keyne, R.S.O., Cornwall, Manager of Explosives Factory.
1891. Eastwick, Jos. H., 2216, North 51st Street, Philadelphia, Pa., U.S.A., Chemist.
1885. Eastwood, Edw., 7, Bolton Road, Port Sunlight, Birkenhead, Soapmaker.
1902. Eastwood, Robert F., 90, Peel House Lane, Widnes, Chemist.
1906. Eaton, B. J., Institute of Medical Research, Kuala Lumpur, Selangor, Fed. Malay States, Government Chemist.
1903. Eaton, Edward N., 1628–315, Dearborn Street, Chicago, Ill., U.S.A., Chemist.
1902. Eckel, Edwin Clarence, U.S. Geological Survey, Washington, D.C., U.S.A., Geologist.
1892. Eddy, Harrison P., Sewage Purification Works, Worcester, Mass., U.S.A., Superintendent.
1901. Eddy, W. Clifton, corner of Glover and Penn Streets, Woodbury, N.J., U.S.A., Superintendent.
1894. Ede, Henry E., 10 Violet Bank, Nether Edge, Sheffield, Chemist.
1885. Edge, Anthony, 79, Milton Street, Readville, Mass., U.S.A., Chemist.
1900. Edgerley, Daniel W., Chilton Paint Co., 120, High Street, Boston, Mass., U.S.A., Chemist.
1902. Edison, Thos. Alva, Edison Laboratory, Orange N.J., U.S.A., Inventor and Manufacturer.
1902. Edwards, H. Seaton, 19, Park Road, Port Sunlight, Cheshire, Analyst.
1903. Edwards, R. S., Columbia Hotel, Portland, Maine, U.S.A., Chemist.
1906. Egleson, J. E., Capelton, Quebec, Canada, Chemist.
1895. Ehrenfeld, Prof. Chas. H., York Collegiate Institute York, Pa., U.S.A., Professor of Chemistry.
1896. Ehrhardt, Ernest F., Badische Anilin und Soda Fabrik, Ludwigshafen a/Rhein, Germany Research Chemist.
1895. Ekenberg, Dr. M., 72, Victoria Street, Westminster S.W., Technical Chemist.
1885. Elborough, T., 59, Mark Lane, London, E.C. Manure Manufacturer.
1901. Elkan, Leo A., 594, Dearborn Avenue, Chicago Ill., U.S.A., Tanner.
1901. Elkins, Arthur W., 520, Park Avenue, East Orange N.J., U.S.A., Civil Engineer.
1884. Elliott, Dr. A. H., Consolidated Gas Co., 4, Irvin Place, New York City, U.S.A., Chemist.
1906. Elliott, Edward, c/o Reckitt and Sons, Ltd. Bourke Street, Redfern, Sydney, N.S.W. Chemical Engineer.
1907. Elliott, George K., c/o Lunkenheimer Co., Cincinnati, Ohio, U.S.A., Chief Chemist.
1896. Elliott, Dr. J. F., c/o Grimwade and Co., 6, Trinity Square, E.C.; and (Journals), O'Connell Street Sydney, N.S.W., Manufacturing Chemist.
1904. Elliott, Philip, c/o Lanosoap, Ltd., Marion Street Works, Bradford, Yorks, Works Chemist.
1902. Elliott, Victor G., Chemical Works, Rozelle, Sydney N.S.W., Australia, Manufacturing Chemist.
1906. Ellis, Arthur E., 7, West 129th Street, New York City, U.S.A., Chemist.
1905. Ellis, Carleton, 168, South Broadway, White Plains N.Y., U.S.A., Chemical Engineer.
1885. Ellis, C. J., Almorah Villa, Milngavie, near Glasgow Technical Chemist.
1893. Ellis, E. Victor, 7, Hillside Crescent, Edinburgh Analytical Chemist.

1894. Ellis, G. Bolee, 70, Chancery Lane, London, W.C., Patent Agent.
O.M. Ellis, T., 120, Regent Road, Leicester, Chemical Merchant.
1907. Ellis, Theodore H., 641, Calvert Building, Baltimore, Md., U.S.A., Oil Refiner.
1891. Ellis, Prof. W. Hodgson, School of Practical Science, Toronto, Ont., Canada, Professor of Applied Chemistry.
1891. Ellison, Henry, Northfield, Cleckheaton, Yorks., Manufacturing Chemist.
O.M. Elmore, A. S., 4, Broad Street Place, London, E.C., Electro-Metallurgist.
1907. Elsden, A. Vincent, 77, Coleraine Road, Blackheath, S.E., Analytical Chemist.
1904. Elson, J. Hugh, Monroe Drug Co., Unionville, Mo., U.S.A., General Manager.
1901. Emerson, Dr. W. H., Georgia School of Technology, Atlanta, Ga., U.S.A., Professor of Chemistry.
1902. Emery, Arthur L., c/o Smith, Emery and Co., 1068, Broadway, Oakland, Cal., U.S.A., Chemical Engineer.
1905. Emery, Delevan, Bradford, Pa., U.S.A., Oil Refiner.
1899. Emery, E. G., Pinole, Contra Costa Co., Cal., U.S.A., Technical Chemist and Engineer.
1907. Emmons, Frank W., c/o Washburn Crosby Co., Minneapolis, Minn., U.S.A., Chemist.
1907. Emrich, Horace H., Perth Amboy Plant, Am. S. and R. Co., Mauser, N.J., U.S.A., Mining Engineer.
O.M. Endemann, Dr. H., 23, William Street, New York City, U.S.A., Analytical Chemist.
1897. Enequist, Erik W., 1651, New York Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1894. Enequist, John, 3710, Avenue J., Brooklyn, N.Y., U.S.A., Chemical Engineer.
1904. Englehard, Charles, 41, Cortlandt Street, New York City, U.S.A., Platinum Importer.
1895. English, Frank H., 47, Shelley Avenue, East Ham, E., Analytical Chemist.
1899. Enright, Bernard, c/o St. Louis Portland Cement Co., St. Louis, Mo., U.S.A., Chemist.
1906. Ephraim, Dr. Julius, Königgraetzerstrasse 69, Berlin, S.W., 11, Germany, Chemist and Patent Agent.
1904. Erdmann, Prof. Dr. H., Bismarck Strasse 12 II., Charlottenburg, Berlin, Professor of Inorganic Chemistry.
1907. Erdoes, Julius, 242, East 122nd Street, New York City, U.S.A., Chemical Engineer.
1902. Erhart, Wm. H., 81, Maiden Lane, New York City, U.S.A., Manufacturing Chemist.
1904. Ermen, Walter F. A., 10, Marsden Street, Manchester, Analytical Chemist.
1905. Ernst, C. A., Lansdowne, Pa., U.S.A., Chemist.
1888. Erskine, J. K., P.O. Box 88, Benoni, Transvaal, Analytical Chemist.
1897. Escher, Paul, c/o Smith, Emery and Co., 1068, Broadway, Oakland, Cal., U.S.A., Chemist.
1884. Eslman, A., 25, Roe Lane, Southport, Lancashire, Analytical Chemist.
O.M. Estcourt, C., 5, Seymour Grove, Old Trafford, Manchester, Consulting Chemist.
1905. Etheridge, Arthur T., 22, Ardoch Crescent, Stevenston, Ayrshire, N.B., Chemist.
1903. Euler, C. G., 18-20, Platt Street, New York City, U.S.A., Agent for Essential Oils.
1883. Evans, Enoch, 660, Coventry Road, Birmingham, Accountant.
1898. Evans, Ernest D., The Western Tanning Co., Bedminster, Bristol, Tanner.
1903. Evans, F. Sparke, Avonside Tannery, Bristol, Tanner.
1905. Evans, Geo. A., 332, Yonge Street, Toronto, Canada, Pharmacist.
1896. Evans, Jacob V. R., Ridgway, Pa., U.S.A., Chemist.
1894. Evans, James Bittenhouse, 19, High Street, Pottstown, Pa., U.S.A., Chemist.
1883. Evans, Sir John, K.C.B., F.R.S., Britwell, Berkhamsted, Herts, Paper Maker.
1905. Evans, John, 67, Surrey Street, Sheffield, Analytical Chemist.
1899. Evans, R. E., 3, Glanrea, Stratford-on-Avon, Brewing Chemist.
1896. Evans, Dr. Thos., University of Cincinnati, Ohio, U.S.A., Instructor in Technical Chemistry.
1903. Evans, Wm. J., 91, Fulton Street, New York City, U.S.A., Manufacturing Chemist.
1898. Evans, Wm. Perceval, Canterbury College, Christchurch, New Zealand, Professor of Chemistry.
1904. Everitt, Walter, 83, The Grove, Ealing, W., Analyst.
O.M. Evershed, F., c/o Clarke, Nickolls and Coombs, Hackney Wick, N.E., Chemist.
1903. Evershed, John, Union Oil Mills, Copenhagen Place, Limehouse, E., Chemist.
1907. Eves, Archie P., 762, East Buchtel Avenue, Akron, Ohio, U.S.A., Chemist.
1894. Ewan, Dr. Thos., 57, Montgomerie Street, Kirklee, Glasgow, Chemist (Aluminium Co.).
1904. Ewing, Dr. A. Ramsay, 1, Alton Gardens, Hillhead, Glasgow, Technical Chemist.
1892. Exley, Arthur, Braemore, Vesper Road, Kirkstall, Leeds, Tanner.
1905. Eynon, Lewis, 57, Darenth Road, Stamford Hill, N., Chief Chemist (London Beetroot Sugar Association).

F

1898. Fadé, Louis, c/o Dr. F. Stockhausen, Deutsche Gold und Silber Scheide-Anstalt, Frankfort a/M., Germany, Chemist and Director.
O.M. Fahlberg, Dr. C., Nassau a/Lahn, Germany, Manufacturing Chemist.
1902. Fahrig, Dr. Ernst., 3642, Old York Road, Philadelphia, Pa., U.S.A., Consulting Chemical Engineer.
1902. Faill, Jas., 51, Partickhill Road, Glasgow, Technical Chemist.
1902. Fairchild, Benj. T., P.O. Box 1120, New York City, U.S.A., Manufacturing Chemist.
1905. Fairchild, Jno. G., 150, Rodney Street, Brooklyn, N.Y., U.S.A., Chemist.
1903. Fairhall, E. J., c/o A. Boake, Roberts & Co., Ltd., 4, Rue Lamartine, Lille (Nord), France, Chemist.
O.M. Fairley, T., 17, East Parade, and (Communications) 8, Newton Grove, Leeds, Analytical Chemist.
O.M. Fairlie, H. C., Camelon Chemical Works, Falkirk, N.B., Chemical Manufacturer.
1901. Fairlie, Jas., Camelon Chemical Works, Falkirk, N.B., Manufacturing Chemist.
1894. Fairweather, Wallace, 62, St. Vincent Street, Glasgow, Patent Agent.
1902. Fairweather, Wallace C., 65-66, Chancery Lane, W.C., Engineer.
1898. Falding, F. J., 55, Broadway, New York City, U.S.A., Chemical Engineer.
1891. Fallon, J. H. M., Boulhaf-le-Dyr, Ligne de Tebessa, Algeria, Fertiliser Expert.
1897. Farmer, John E., Beddington Farm, near Croydon, Assistant Manager (Sewage Works).
O.M. Farrant, N., c/o J. Nicholson and Sons, Chemical Works, Hunslet, Leeds, Chemist.
1897. Farrell, Frank J., 44, Prince of Wales Mansions, Battersea Park, S.W., Analytical Chemist.
O.M. Farries, T., 12, Coleman Street, London, E.C., Manufacturing Chemist.
O.M. Farrington, T., 5, Summerhill Terrace, Cork, Ireland, Chemical Engineer.
1902. Fasnacht, E. A., The Hollies, Clayton Bridge, Manchester, Technical Chemist.
O.M. Faulkner, F., The Laboratory, 83, Bath Row, Birmingham, Consulting Brewer's Chemist.
1891. Fawcett, Jas. H., c/o Bank of Australasia, 4 Threadneedle Street, London, E.C., Metallurgist.
1884. Fawsitt, C. A., Atlas Chemical Works, East Milton Street, Glasgow, Chemical Manufacturer.
1903. Fawsitt, Dr. Chas. E., 9, Tennessee Terrace, Glasgow, Assistant in Chemistry.

1906. Easley, Edward J., 88, Broad Street, Boston, Mass., U.S.A., Aniline Colour Dealer.
1903. Feilmann, Dr. M. E., 92, Victoria Street, Westminster, S.W., Chemist.
1902. Feld, Walther, Hauptstrasse 14, Zehlendorf-Wannseebahn, Germany, Chemical Works Director.
1905. Felton, Herbert L., 524, East Second Street, South Boston, Mass., U.S.A., Distiller.
1899. Ferguson, Geo., Gleniffer Soap Works, Paisley, N.B., Soap Manufacturer.
1900. Ferguson, Geo. A., College of Pharmacy, 115, West 68th Street, New York City, U.S.A., Professor of Analytical Chemistry.
1896. Ferguson, J. Hart, Loch Katrine Distillery, Camlachie, Glasgow, Distillery Manager.
O.M. Ferguson, Prof. J., The University, Glasgow, Professor of Chemistry.
1902. Fergusson, Donald M., c/o Acadia Sugar Refining Co., Halifax, N.S., Canada, Analytical Chemist.
1883. Fergusson, H., Prince Regent's Wharf, Victoria Docks, E., Technical Chemist.
1905. Fernberger, Harry M., Dollar Bay, Houghton Co., Mich., U.S.A., Chemist.
1906. Fernyhough, F., The Abbey Cottage, Leek, Staffordshire, Printworks Manager.
1905. Fiebiger, Peter, 530, Canal Street, New York City, U.S.A., Colour Chemist.
1893. Fiebing, John H., 644, 28th Street, Milwaukee, Wis., U.S.A., Leather Trade Chemist.
1905. Field, Charles, III., 57, Waban Hill Road, Chestnut Hill, Mass., U.S.A., Research Chemist.
1885. Field, E. W., Cloud House, Sandiacre, near Nottingham, Brewer.
1887. Field, S. S., 3, Glenluce Road, Blackheath, S.E., Manufacturing Chemist.
1891. Field, Wm. Eddington, 65, Sutherland Road, Armadale, Melbourne, Victoria, Chemist.
1884. Filcock, P., Sunny Bank, Prestbury Road, Macclesfield, Analytical Chemist.
1900. Fillis, Frank, Brookland, London Road, Neath, South Wales, Cement Works Manager.
1907. Finch, Archibald M., Vitriol and Chemical Works, Cwmbran, R.S.O., Monmouthshire, Chemical Manufacturer.
1904. Finch, Martin L., Vitriol and Chemical Works, Cattedown, Plymouth, Chairman of Directors.
1905. Findlay, Dr. Alex., The University, Birmingham, Lecturer on Physical Chemistry.
1899. Fingland, Jno. J., Sandon, B.C., Canada.
1899. Finley, Norval H., 7229, Hermitage Street, Belmar Station, Pittsburg, Pa., U.S.A., Chemist.
1904. Finn, Cornelius P., Pontefract Road, Castleford, Yorks, Technical Chemist.
1903. Fischer, Dr. Carl, 213–215, Water Street, New York City, U.S.A., Chemist.
1903. Fish, Chas. C. R., 10, Park Square, Boston, Mass., U.S.A., Chemist.
1905. Fish, Chas. H., Cocheco Manufacturing Co., Dover, N.H., U.S.A., Textile Manufacturer.
1900. Fisher, Henry, 57, East 63rd Street, New York City, U.S.A., Teacher of Chemistry.
O.M. Fisher, W. W., 5, St. Margaret's Road, Oxford, Chemical Lecturer.
1906. Fiske, Aug. H., 141, Milk Street, Boston, Mass., U.S.A., Chemist.
1895. Fison, Jno., Messrs. Jas. Fison and Sons, Thetford, Norfolk, Chemical Manufacturer.
1904. Fitch, A. J., 19, Grange Road, Canonbury, N., Brewer's Chemist.
O.M. Fitzbrown, G., Ditton Copper Works, Widnes, Metallurgist.
1897. Fitzgerald, Francis A. J., Fitzgerald and Bennie Laboratories, P.O. Box 29, Niagara Falls, N.Y., U.S.A., Chemical Engineer.
1902. FitzGibbon, Thos., 116, Harbord Street, Fulham, S.W., Analytical Chemist.
1900. Fitz-Randolph, E. R., State Laboratory of Hygiene, Trenton, N.J., U.S.A., Bacteriologist and Chemist.
1893. Flamme, E., c/o Kraemer and Flamme, Halbrenn a/N., Germany, Manufacturing Chemist.
1901. Flavelle, Jos. W., Toronto Technical School, College Street, Toronto, Canada, Chemist.
1892. Fleming, J. Arnold, Britannia Pottery, 126, Glebe Street, Glasgow, Potter.
1903. Fleming, Jno. A., 1757, Willard Street, N.W., Washington, D.C., U.S.A., Engineer.
O.M. Fletcher, A. E., Coombe Lea, Dorking, Surrey, Ex-Chief Inspector Alkali, &c., Works.
1893. Fletcher, E. Morley, 3, Woodhouse Cliff, Leeds, Alkali Works Inspector.
O.M. Fletcher, F. W., c/o Fletcher, Fletcher & Co., Ltd., Holloway, N., Manufacturing Chemist.
1891. Fletcher, R. Jaques, North Geelong, Victoria, Manufacturing Chemist.
1904. Fletcher, Wm. E., Box 83, Tamaqua, Pa., U.S.A., Chemist.
1899. Focht, Louis, 105, E. Hanover Street, Trenton, N.J. U.S.A., Civil Engineer.
1890. Foden, Alfred, 19, Lancaster Avenue, Sefton Park, Liverpool, Metallurgical Chemist.
1900. Foersterling, Dr. H., c/o Roessler Hasslacher Chem. Co., Perth Amboy, N.J., U.S.A., Chemist.
1900. Fogetti, Lucien, 4070, Lake Avenue, Chicago, Ill., U.S.A., Chemist.
1895. Fogg, Chas. A., Graythorne, Albert Road, Bolton-le-Moors, Lecturer on Chemistry.
1901. Folsom, Herbert A., 112, Water Street, Boston, Mass., U.S.A., Textile Chemist.
1900. Forbes, Eli, Clinton, Mass., U.S.A., Chemist.
1895. Forbes, Paul R., 15, William Street, New York City, U.S.A., Chemist and Assayer.
1893. Ford, J. B., jun., Michigan Alkali Co., Wyandotte, Mich., U.S.A., Secretary and Treasurer.
1889. Ford, Jno. S., Abbey Brewery, Edinburgh, Analyst.
1905. Foregger, Dr. R. von, c/o Roessler & Hasslacher Chemical Co., 100, William Street; and (Journals) P.O. Box 1999, New York City, U.S.A., Chemist.
1899. Forel, Geo., 18, Rue Hohenlohe, Strasburg, Alsace, Germany, Chemist.
1885. Formoy, J. Arthur, Chestham, Grange Road, Sutton, Surrey, Oil Expert.
1904. Forrest, Chas. N., New York Testing Laboratory, Long Island City, N.Y., U.S.A., Chemist.
1898. Forrest, J. Kerr, Hawsleigh, Balaclava Road, St. Kilda East, Victoria, Australia, Manufacturing Chemist.
1890. Forrester, A. M., c/o Richmond Guano Co., Richmond, Va., U.S.A., Analytical Chemist.
1905. Forrester, H. A., Usina de Gas, Retiro, Buenos Ayres, S. America, Chemical Works Manager.
1902. Forstall, Alf. E., 58, William Street, New York City, U.S.A., Consulting Gas Engineer.
1901. Forster, Miss E. L. B., King's College, Strand, London, W.C., Analyst.
1902. Forster, Ferdinand E. P., c/o Messrs. Bass and Co., 19, Guild Street, Burton-on-Trent, Chemist.
1899. Forster, Dr. M. O., F.R.S., Royal College of Science, South Kensington, S.W., Demonstrator of Chemistry.
1884. Forster, Ralph C., c/o Messrs. Bessler, Waechter, and Co., 18 and 19, Fenchurch Street, London, E.C., Chemical Merchant.
1884. Forth, Henry, Meadowcroft, Marple, Cheshire, Drysalter.
1907. Forward, Charles C., Iroquois, Ontario, Canada, Chemist.
O.M. Foster, R. Le Neve, Bollindane, Wilmslow, Cheshire, Manufacturing Chemist.
1906. Foster, Robt. K., 120, Victoria Parade, Collingwood, Melbourne, Victoria, Pharmaceutical Chemist.
1888. Foster, Wm., St. Martin's Terrace, Newton Park, Leeds, Manufacturing Chemist.
1903. Fotheringham, John, North Brazilian Sugar Factories, Ltd., Tiuma, Pernambuco, Brazil, Chemist.
1906. Foucar, J. Louis, 29, St. John's Park, Blackheath, S.E., Chemist.
1904. Foust, Thomas B., c/o Box Ash C. & I. Co., Abbott Creek, Tenn., U.S.A., Chemist.

1891. Fowler, Sir Gilbert J., Broad Oak, Urmston, near Manchester, Consulting Chemist (Manchester Corporation Rivers Committee).

1898. Fowler, Thos. V., P.O. Box 168, Buffalo, N.Y., U.S.A., Chemical Works Manager.

1903. Fox, A. Stanley, Rosehurst, Athelstan Road, Faversham, Kent, Chemist (Cotton Powder Co., Ltd.).

1898. Fox, Jno., 42, Highfield Road, Rock Ferry, Cheshire, Analyst.

O.M. Fox, T., jun., c/o Fox, Bros. and Co., Ltd., Wellington, Somerset, Wool Manufacturer.

1905. France, Edward W., Philadelphia Textile School, Broad and Pine Streets, Philadelphia, Pa., U.S.A., Director.

1901. France, G. Herbert, Woodroyd Dyeworks, Low Moor, Bradford, Yorks., Dyer.

1899. Franchot, Stanislaus P., c/o National Electrolytic Co., Niagara Falls, N.Y., U.S.A., Chemist.

1885. Francis, Edwd., Park Ravine, Nottingham, Chemical Lecturer.

O.M. Francis, E. G., 29, Matheson Road, West Kensington, W., Glucose Works Manager.

O.M. Francis, G. B., 38, Southwark Street, London, S.E., Wholesale Druggist.

O.M. Francis, W. H., Cleveland, Thornton Road, Clapham Park, S.W., Wholesale Druggist.

1902. Francksen, Dr. Aug., 4903, Garden Street, Bridesburg, Philadelphia, Pa., U.S.A., Chemist.

1906. Frank, Prof. Dr. A., Berlinerstrasse 26, Charlottenburg, Germany, Chemist.

1894. Frank, Jerome W., 29, Broadway, New York City, U.S.A., Chemist.

1886. Frankenburg, Isidor, Greengate Rubber Works, Salford, Manchester, India-rubber Manufacturer.

1895. Frankforter, Dr. G. B., University of Minnesota, Minneapolis, Minn., U.S.A., Prof. of Chemistry.

1904. Frankl, A., Clotilde Chemical Works, Nagy Bocskó, Hungary, Chief Manager.

O.M. Frankland, H., Streonshalh, The Crescent, Linthorpe, Middlesbro', Analytical Chemist.

O.M. Frankland, Prof. P. F., F.R.S., The University, Birmingham, Professor of Chemistry.

1906. Fraps, Geo. S., Texas A. & M. College, College Station, Texas, U.S.A., Professor of Chemistry.

1904. Frasch, George B., Chemist.

1901. Frasch, Hans A., 52, Broadway, New York City, U.S.A., Manager.

1900. Frasch, Herman, 82, Beaver Street, New York City, U.S.A., Oil Refiner.

1904. Fraser, Jas. D., 8, Percy Street, Ibrox, Glasgow, Chemist.

1891. Fraser, L. McG., 98, Commercial Road East, London, E., Chemical Engineer.

1902. Fraser, R. A., 519, Produce Exchange, Manchester, Fellmonger.

1886. Fraser, W. J., 121, Adelaide Road, London, N.W., Mechanical Engineer.

1907. Fraser, Wm. M., c/o The Texas Co., Port Arthur, Texas, U.S.A., Chemist.

1902. Frederick, Geo. E., jun., P.O. Box 762, New York City, U.S.A., Chemical Merchant.

1885. Freear, H. M., Hardwick Road, Woburn Sands, Beds., Analytical Chemist.

1899. French, Alf., St. Bartholomew's Hospital, Rochester, Kent, Dispenser.

1900. French, Thos., 1, Kelvinside Terrace West, Glasgow, Chemist.

1903. Frerichs, Dr. F. W., Herf and Frerichs Chemical Co.; and (Journals), 3823, Westminster Place, St. Louis, Mo., U.S.A., Manufacturing Chemist.

1903. Frew, John, Dunrod Cottage, Hamilton, N.B.

1907. Frewing, Henry, c/o Otto Isler and Co., Manchester, Chemical Merchant.

1908. Friend, C. Cleaver, c/o The D. B. Martin Co., 2001, North 24th Street, Philadelphia, Pa., U.S.A., Chemist.

1894. Frey, H., [illegible] E. 52, Beach Street, New York

1902. Frey, Jno. W., Waukesha, Schuh, [illegible] U.S.A., Cotton Manufacturer.

O.M. Friswell, R. J., 43-48, St. Dunstan Street, London, E.C., Consulting Chemist.

1898. Frith, J. Mason, Linden Lodge, Runcorn, Cheshire, Lime Burner.

1899. Fritzsche, Karl, c/o Schimmel and Co., Miltitz, near Leipsig, Germany, Manufacturer of Essential Oils.

1906. Frohner, Edward, jun., c/o Standard Table Oil Cloth Co., Youngstown, Ohio, U.S.A., Manager.

1890. Frost, Dr. Howard V., 3068, Drexel Boulevard, Chicago, Ill., U.S.A., Professor of Chemistry.

1884. Frost, Joe, Storths Mill, Moldgreen, Huddersfield, Manufacturing Chemist.

O.M. Fryer, Dr. A. C., 13, Eaton Crescent, Clifton, Bristol, Alkali Works Inspector.

1904. Fryer, Percival J., 27, Minster Road, West Hampstead, N.W., Analyst.

1906. Fuchs, Herman C., 83, Marlborough Road, Brooklyn, N.Y., U.S.A., Dry Colour Chemist.

1903. Fudge, T., 604, Avenue E., Bayonne, N.J., U.S.A., Chemist.

1889. Fuerst, Jos. F., 17, Philpot Lane, London, E.C., Chemical and Oil Merchant.

1895. Fuerst, W. F., 2, Stone Street, New York City, U.S.A., Chemical Merchant.

1894. Fuller, Chas. J. P., 603, Chorley New Road, Horwich, near Bolton, Analytical Chemist.

1902. Fuller, Henry C., c/o E. E. Brown, 6, State Street, Worcester, Mass., U.S.A., Analytical Chemist.

1899. Fuller, Robt. F., Neston Park, Corsham, Wilts., Rubber Manufacturer.

1899. Fuller, W. M., c/o Morris and Griffin, Malindee, Newport, Mon., Chemical Manufacturer.

O.M. Fuller, Wm., 8, Orchard Road, Blackheath, S.E., Chemist.

1898. Fulmer, Elton, Pullman, Wash., U.S.A., Professor of Chemistry.

1896. Fulton-Smith, I., 20, Bold Street, Warrington, Brewer.

1906. Furlong, John R., 182, Commercial Road, London, E., Research Chemist.

1906. Futers, Stephen H., Glenraven House, Hael-y-Fal, Maesteg, Glamorgan, Analyst.

1885. Fyfe, Jno., 7, West George Street, Glasgow, Oil Works Director.

G

1898. Gabain, Chas. E., Messrs. Gabain Frères, Havre, France, Manufacturer of Edible Fats.

O.M. Gabbett, E. R., 64, Vanbrugh Road, Blackheath, S.E.; (Journals) Prince Regent's Wharf, Silvertown, E., Chemical Engineer.

1904. Gadd, Henry Wippell, 190, Pace Street, Boston, Analytical Chemist.

1906. Gagnebin, Chas. L., 140, Oliver Street, Boston, Mass., U.S.A., Dyestuff Merchant.

1890. Gajjar, T. K., Techno-chemical Laboratory, Girgaum, Bombay, India, Consulting Chemist.

1884. Gall, Henry, 4, Rue Albert July, Versailles, France, Technical Chemist.

1905. Gall, J. B., c/o Callender's Cable and Construction Co., Belvedere, Kent, Chemist.

1897. Gallatly, J. C., 101, Armadale Street, Dennistoun, Glasgow, Assistant to Professor of Metallurgy.

1905. Gallinagh, James P., Electricity Works, Limerick, Ireland, Borough Electrical Engineer.

1901. Gallivan, Frank B., 48, Wallingford Road, Boston, Mass., U.S.A., Chemist.

1903. Gallum, Albert F., Milwaukee, Wis., U.S.A., Tanner.

1901. Gallup, W. Arthur, Amstel Printworks, North Adams, Mass., U.S.A., Printer.

1901. Galpin, Henry P., 32, West 23rd Street, New York City, U.S.A., Chemist.

1901. Galt, Hugh, Alum, Ontario, Canada, [illegible]

1887. Gamble, Jas. N., The Laboratory, Procter and Gamble Co., Ivorydale, Ohio, U.S.A., Soap Manufacturer and Oil Refiner.
O.M. Gamble, Sir Josias, Bart., Haresfinch, St. Helens, Lancs., Chemical Manufacturer.
1894. Gane, Eustace H., 95, Fulton Street, New York City, U.S.A., Pharmaceutical Chemist.
1888. Gans, Adolf, Farbenfabrik von L. Cassella & Co., Frankfort a/Main, Germany, Dye Works Manager.
1901. Gansser, Dr. A., c/o Messrs. Lepetit, Dollfus and Gansser, Garessio-Ponte (Provincia di Cuneo), Italy, Chemical Engineer.
1896. Gardair, Aimé, 51, Rue St. Ferréol, Marseilles, France, Director of Chemical Co.
1893. Gardiner, H. J., 90, Cannon Street, London, E.C., Chemical Manufacturer.
1905. Gardner, Franc E., 633, North Western Avenue, Chicago, Ill., U.S.A., President, Gardner-Barada Chemical Co.
1891. Gardner, Prof. Walter M., Technical College, Bradford, Director of Chemistry and Dyeing Department.
1897. Garfield, Jos., Thackley, Bradford, Yorks., Civil Engineer.
1888. Garibaldi, Joachim A., 21, Church Place, Gibraltar, Chemist.
1905. Garle, John L., Sanctuary House, Tothill Street, Westminster, Consulting Chemist.
1904. Garnar, G. Lestor, Monticello, Sullivan Co., N.Y., U.S.A., Superintendent of Leather Works.
1904. Garnaus, John C., P.O. Box 326, New York City, U.S.A., Dyestuff Merchant.
1890. Garrett, Dr. F. C., Armstrong College, Newcastle-on-Tyne, Teacher of Science.
1900. Garrigues, W. E., Foot of Lieb Street, Detroit, Mich., U.S.A., Chemical Engineer.
1906. Garroway, Major John, 58, Buchanan Street, Glasgow, Chemist.
1899. Garroway, Wm., 694, Duke Street, Glasgow, Chemical Manufacturer.
1898. Garry, H. Stanley, 66, Mapperley Road, Nottingham, Manure Works Manager.
O.M. Garton, R., Messrs. Hill, Garton, & Co., Southampton Wharf, Battersea, S.W., Glucose Manufacturer.
1886. Gascoyne, Dr. W. J., 2741, North Charles Street, Baltimore, Md., U.S.A., Analytical Chemist.
O.M. Gaskell, Holbrook, Woolton Wood, Woolton, near Liverpool, Alkali Manufacturer.
O.M. Gaskell, Holbrook, jun., Erindale, Frodsham, Cheshire, Engineer.
1902. Gaskell, Holbrook III., Hillcroft, Church Road, Woolton, near Liverpool, Engineer.
1897. Gaster, Leon, 32, Victoria Street, Westminster, S.W., Electrical Engineer.
1895. Gate, Tom Erskine, (Journals) The Santubong Cutch and Tanning Extract Co., Ltd., Santubong, Sarawak, Borneo, and (subscriptions) Calder House, Dewsbury, Yorks., Manufacturing Chemist.
O.M. Gatheral, Geo., 174, Soho Hill, Handsworth, Birmingham.
1906. Gaunt, Percy, Norman Road, Rusholme, Manchester, Chemist.
1903. Gaylord, Wallace K., Throop Polytechnic Institute, Pasadena, Cal., U.S.A., Professor of Chemistry.
1904. Gazdar, J. J., 5, Wroxham Mansions, Canfield Gardens, South Hampstead, N.W., Barrister-at-Law.
1905. Geisenheimer, Albert, P.O. Box 994, New York City, U.S.A., Dyestuff Merchant.
1891. Geisler, Dr. Jos. F., New York Mercantile Exchange Building, 6, Harrison St., New York City, U.S.A., Consulting Chemist.
1901. Gemmell, G. H., 4, Lindsay Place, George IV. Bridge, Edinburgh, Analytical Chemist.
1901. Gent, Percy W., 789, Highland Avenue, Forest Hill, Newark, N.J., U.S.A., Chemist.
1897. Gent, Wm. T., Springfield, Misterton, near Gainsboro', Metallurgical Chemist.
1905. Genth, Fred. A., jun., 232, Walnut Street, Philadelphia, Pa., U.S.A., Chemist.
1905. George, J. K., 60, Wall Street, New York City, U.S.A., Manufacturer.
1902. George, Wm. K., c/o Standard Silver Co., Ltd., 35, Hayter Street, Toronto, Ont., Canada, Manufacturer.
1903. Georgii, Max, 606, F. Street, N.W., Washington, D.C., U.S.A., Patent Attorney.
1904. Gerard, Thos. A., 122, Foxhill Road, Nottingham, Soap Manufacturer.
1906. Gerkensmeyer, Henry H., 109, South Eastern Avenue, Joliet, Ill., U.S.A., Chemist.
O.M. Gerland, Dr. B. W., 105, Plantation Street, Accrington, Consulting Chemist.
1905. Geussler, Dr. Otto, c/o Farbenfabr. vorm. F. Bayer, Elberfeld, Germany, Chemist.
1903. Ghose, Anukul, 42, Shambazar Street, Calcutta, India, Analyst.
1891. Gibb, Thos., Wilford, Dornoch Terrace, Brisbane, Queensland, Metallurgist.
1903. Gibbings, Wm., 11, Howard Drive, Grassendale, Liverpool, Works Manager.
O.M. Gibbins, H. B., 177, Redland Road, Bristol
1902. Gibbon, Edw., Belvedere, Park Road, Clydach, R.S.O., Glam., Works Chemist.
1904. Gibbs, A. E., Wyandotte, Mich., U.S.A., Manufacturing Chemist.
1883. Gibbs, D. Cecil, Soap Manufacturer.
O.M. Gibbs, Wm. P., Fabriken, Hjerpen, Jemtland, Sweden, Analytical Chemist.
1893. Gibbs, W. T., Buckingham, Prov. Quebec, Canada, Manufacturing Chemist.
O.M. Gibson, Dr. J., 20, George Square, Edinburgh, Chemical Lecturer.
O.M. Gibson, J. M., c/o Buckley Brick and Tile Co., Buckley, *via* Chester, Brick and Tile Manufacturer.
1905. Gibson, John, Victorian Portland Cement Works, Burnley Street North, Richmond, Vic., Australia, Manager.
1906. Gibson, Robt. R., Boise, Idaho, U.S.A., Chemist.
1905. Gibson, Wm. F., Burham Cement Works, near Aylesford, Kent, Works Chemist.
1904. Giese, Otto E., 4, Cedar Street, Manhattan, New York City, U.S.A., Importer.
1899. Gifford, Wm. E., 408, New Jersey Railroad Avenue, Newark, N.J., U.S.A., Chemist.
1892. Gilbard, T. Francis H., 245, Dalston Lane, Hackney, N.E., Analytical Chemist.
1905. Gilbertson, Isaac H., 5, Broad Street, Rhodes, near Middleton, Lancs., Calico Printer.
1903. Gilby, Joseph W., c/o Brotherton and Co., Ltd., Haigh Park Chemical Works, Stourton, Leeds, Works Chemist.
O.M. Gilchrist, Percy Carlyle, F.R.S., A.R.S.M., M.Inst.C.E. & M.E., Chequer Lawn, St. Albans, Herts.
1884. Gilchrist, Peter S., Charlotte, N.C., U.S.A., Chemical Engineer.
1900. Gildersleeve, W. H., Middlesboro', Ky., U.S.A., Chemist.
O.M. Giles, W. B., The Grange, Leyton, Essex, Chemical Manufacturer.
1886. Gill, Dr. Aug. H., Massachusetts Institute of Technology, Boston, Mass, U.S.A., Assoc. Professor of Technical Analysis.
1901. Gill, Wm. S., c/o Farquhar and Gill, North of Scotland Colour Works, Aberdeen, Colour and Varnish Manufacturer.
1903. Gillean, R. Hampson, c/o General Chemical Co., Bayonne, N.J., U.S.A., Chemist.
1901. Gilles, Wm. S., The Cottage, Rocking, near Braintree, Essex, Technical Chemist.
1903. Gillett, Wm. Lowry, Hotel San Remo, Central Park West and 75th Street, New York City, U.S.A., Chemical Engineer.
1906. Gillies, Donald B., Tonopah, Nevada, U.S.A., Mining Engineer.
1905. Gilliland, Elijah P., 79, Highland Avenue, Salem, Mass., U.S.A., Foreman Tanner.
1888. Gillman, Gustave, Ferrocarril de Murcia a Granada, Aguilas, Prov. de Murcia, Spain, Civil Engineer.

1892. Gilmour, J. D., 192, Bathcadgens Road, Glasgow, Chemist.
1891. Gimingham, Edw. A., 28, Stamford Hill Mansions, Stamford Hill, N., Electrician.
1904. Ginsburg, Louis, 438, Main Street, New Britain, Conn., U.S.A., Match Manufacturer.
1886. Girdwood, Dr. G. P., 111, University Street, Montreal, Canada, Professor of Chemistry.
1906. Girtin, Thomas, H. L. Raphael's Refinery, Thomas Street, Burdett Road, London, E., Bullion Refiner.
1903. Gladding, Thos. S., 55, Fulton Street, New York City, U.S.A., Analytical Chemist.
1886. Glaeser, F. A., Carpenters' Road, Stratford, E., Varnish Manufacturer.
1906. Glasel, Dr. Chas. J., Tanner.
1889. Glaser, Chas., 22, South Gay Street, Baltimore, Md., U.S.A., Consulting Chemist.
1906. Glass, A. Melville, 37, Chancery Lane, London, W.C., Patent Agent.
1907. Gleason, Fred. J., Walpole, Mass., U.S.A., Superintendent (Mass. Chemical Co.).
1901. Glegg, Robt., Agricultural Laboratory, Marischal College, Aberdeen, Analytical Chemist.
1894. Glen, Chas., Glengowan Printworks, Caldercruix, N.B., Calico Printer.
1890. Glen, J., jun., Glengowan Printworks, Caldercruix, N.B., Calico Printer.
1900. Glendenning, Arthur, 31, Bright Street, Middlesbrough, Analytical Chemist.
1884. Glendinning, H., Winnington Park, Northwich, Cheshire, Technical Chemist.
1904. Glendinning, T. A., Wellpark Brewery, Glasgow, Brewery Chemist.
1895. Glenn, Wm., Baltimore Chrome Works, 1348, Block Street, Baltimore, Md., U.S.A., Chrome Manufacturer.
1888. Gloag, Robt. F., Grove Hill, Middlesbrough, Secretary
O.M. Glover, G. T., 24, Craven Hill Gardens, Lancaster Gate, W., Chemical Works Manager.
1896. Glover, H., East Falls, Schuylkill, Philadelphia, Pa., U.S.A., Chemical Works Superintendent.
1905. Glover, Nathan H., 355, River Street, Mattapan, Boston, Mass., U.S.A., Gum Manufacturer.
O.M. Glover, William, 25, North View, Heaton, Newcastle-on-Tyne, Technical Chemist.
1903. Goetschius, Howard B., Little Ferry, N.J., U.S.A., Chemist.
1896. Goetz, Isidore, 5, Brondesbury Park, London, N.W., Mine Manager.
1905. Gokhale, Dr. K. N., The Indian Pharmacy, Girgaum, Bombay, India, Manager.
1898. Golding, Jno., Ashby Road, Kegworth, Derby, Agricultural Chemist.
1906. Goldschmidt, Dr. Karl, Chemical Works, Essen-Ruhr, Germany, Manufacturing Chemist.
O.M. Goldschmidt, Dr. S. A., 43-51, Sedgwick Street, Brooklyn, N.Y., U.S.A., Chemical Manufacturer.
1897. Goldschmiedt, Dr. Guido, Laboratory, II Salmgasse 1, Prag, Austria, Professor in Imperial German University.
1895. Goldsmith, Byron B., 19, East 74th Street, New York City, U.S.A., Vice-President (American Lead Pencil Co.).
1899. Goldsmith, Dr. Jno. N., British Xylonite Co., Ltd., Manningtree, Essex, Chemist.
1906. Goodall, Wm. Leslie, Finboro' Road, Stowmarket, Suffolk, Works Chemist.
1900. Goodchild, Wm. H., (Journals) Porcura, Boicza, Vei Devs, Hungary, and (subscriptions) Elmwood Lodge, Long Lane, Finchley, N., Chemist.
1898. Goode, J. Archibald, 18, Crampton Street, London, S.E., Analytical Chemist.
1906. Goodhue, Leonard H., c/o Boston Rubber Shoe Co., Melrose, Mass., U.S.A., Chemist.
1903. Gooding, E. Claude, Willow House, Washford, Somerset, Chemical Student.
1898. Goodrich, Chas. G., Akron, Ohio, U.S.A., Rubber Manufacturer.
1884. Goodwin, C. C., Beechfield, St. Margaret's Road, Altrincham, Cheshire, Accountant.
1894. Goodwin, Dr. W. L., The School of Mines, Kingston, Canada, Professor of Chemistry.
O.M. Goppelsroeder, Dr. F., Lutzenstrasse, 38, Basel, Switzerland, Professor of Chemistry.
1898. Gordon, Colin, Stores' Wharf, Wharf Road, Poplar, E., Chemical Engineer.
1884. Gordon, J. G., Queen Anne's Mansions, Westminster, S.W., Steel Manufacturer.
1883. Gore, Dr. G., F.R.S., 20, Easy Row, Birmingham, Metallurgist.
1906. Gorrie, David, c/o D. Gorrie & Sons, South Methven Street, Perth, N.B., Engineer.
1905. Goraline, Wm. H., Rochester Sewer Pipe Co., Rochester, N.Y., U.S.A., Secretary and Manager.
1891. Gorvin, Jno. C., English Crown Spelter Co., Ltd., Swansea, Works Manager.
O.M. Gossage, F. H., Camp Hill, Woolton, Liverpool, Alkali Manufacturer.
1897. Gossage, W. Winwood, Widnes, Lancashire, Soap Manufacturer.
1904. Gotthelf, August H., Hastings-on-Hudson, N.Y., U.S.A., Chemist.
1890. Goulding, Sir Wm. J., Bart., North Wall, Dublin, Manure Manufacturer.
1903. Govers, F. X., 250, Main Street, Owego, Tioga Co., N.Y., U.S.A., Manager and Chemist.
O.M. Gowland, Prof. W., 13, Russell Road, Kensington, W., Professor of Metallurgy (Royal School of Mines).
1886. Goyder, G. A., 12, Pirie Street, Adelaide, South Australia, Chemist.
1890. Grabfield, Dr. J. P., c/o Morris and Co., 35th Street and 11th Avenue, New York City, U.S.A., Chemist.
1906. Graesser, Norman H., Argoed Hall, Llangollen, N. Wales, Manufacturing Chemist.
1883. Graesser, R., Cefn, near Ruabon, North Wales, Manufacturing Chemist.
O.M. Graham, Prof. C., The Reculvers, Hastings, Consulting Chemist.
O.M. Graham, C. C., Oriel House, Scarborough, Yorks., Technical Chemist.
1883. Grandage, H., City Chambers, 2, Darley Street, Bradford, Dyer.
1897. Granger, Dr. J. Darnell, 25, All Saints Street, Nottingham, Analytical Chemist.
1900. Granja, Rafael, Ceres Chemical Co., Kingston, N.Y., U.S.A., Chemist.
1905. Grant, Alexander, 13, Kilgraston Road, Edinburgh, Baker.
1903. Grant, Henry C., c/o Grasselli Chemical Co., 80, Wall Street, New York City, U.S.A., Manager.
1896. Graves, Geo. H., c/o General Chemical Co., Bridgeport, Conn., U.S.A., Manufacturing Chemist.
1896. Graves, Walter G., 364, Harkness Avenue, Cleveland, Ohio, U.S.A., Chemist.
1895. Gray, Elisha B., c/o United Oil and Refining Co., Beaumont, Texas, U.S.A., Oil Inspector and Chemist.
1884. Gray, G. Watson, 8, Inner Temple, Dale Street, Liverpool, Consulting Chemist and Assayer.
1904. Gray, Jas., Heymann's Laboratory, P.O. Box 3427, Johannesburg, Transvaal, Chemist.
1901. Gray, J. Campbell, Glengoyt, Strines, near Stockport, Printworks Chemist.
1886. Gray, Jno., 13, Queen's Road, Rock Ferry, near Birkenhead, Oil Works Chemist.
1902. Gray, John, Port Credit, Ont., Canada, Starch Manufacturer.
1903. Gray, Jno. Lathrop, c/o Tide Water Oil Co., Foot 22nd Street, Bayonne, N.J., U.S.A., Assistant Superintendent (Paraffin Works).
1896. Gray, Dr. Thos., The Technical College, Glasgow, Professor of Technical Chemistry.
1905. Gray, W. B., Messrs. Lever Bros., Balmain, Sydney, N.S.W., Australia, Analytical Chemist.
1903. Gray, Wm. S., 76, William Street, New York City, U.S.A., Chemical Merchant.
1901. Greaves, Albert E., c/o P. Spence and Sons, Ltd., Goole Alum Works, Goole, Yorks., Works Chemist.
1891. Greaves, I. A. S., Morton, [illegible]

1894. Greaves, Wm., Powell-Duffryn Coal, Ltd., Bye Product Works, Bargoed, near Cardiff, South Wales, Chemical Engineer and Chemist.
1894. Greeff, R. W., 20, Eastcheap, London, E.C., Chemical Agent.
1900. Green, Alfred H., Oaklands, Lowton, Newton-le-Willows, Lancs., Manufacturing Chemist.
O.M. Green, Prof. Arthur G., 49, Cardigan Road, Headingley, and Clothworkers' Department, The University, Leeds, Professor of Dyeing.
1907. Green, Clarence, c/o Nicholson and Co., Beaumont Works, St. Albans, Herts, Chemist.
1906. Green, Ernest, 113, Hulton Street, Moss Side, Manchester, Science Teacher.
1903. Green, G. F. Dudbridge, Lea Conservancy Board, Hackney Wick, N.E., Manufacturing Chemist.
O.M. Green, H., Hayle Mill, Maidstone, Paper Manufacturer.
1896. Green, Jno. Wilberforce, 108, Kenilworth Avenue, Wimbledon Park, S.W., Technical Chemist.
O.M. Green, L., Lower Tovil, Maidstone, Paper Manufacturer.
O.M. Greenaway, A. J., The Orchard, Chertsey, Surrey, Sub-Editor of Chemical Society's Journal.
1906. Greene, George M., 99, Mercer Street, Jersey City, N.J., U.S.A., Chemist.
1884. Greenhalgh, Jas. Herbert, Whitebirk, Green Mount, Bury, Lancs., Assistant Manager of Printworks.
O.M. Greenway, T. J., Chillagoe, North Queensland, Australia, Metallurgist.
1902. Greenwood, Conrad Varley, Horsfield, Colne, Lancs., Cotton Mill Manager.
O.M. Greenwood, Holmes, Regent House, Hartmann Street, Accrington, Lancashire, Technical Chemist.
1897. Gref, Anthony, 128, Duane Street, New York City, U.S.A., Patent Lawyer.
1907. Gregory, Joshua C., 128, Wellington Street, Glasgow, Analytical and Consulting Chemist.
1905. Greiner, F. M., Ensley, Alabama, U.S.A., Steel Melter.
O.M. Greville, H. L., 39, Croft Road, Bromley, Kent, Consulting Chemist.
1906. Grice, Walter T., 9, Dalhousie Square, Calcutta, India, Chemist.
1900. Griffin, Dr. Jno. J., Catholic University of America, Washington, D.C., U.S.A., Professor of Chemistry.
1890. Griffin, Jno. R., Kemble Street, Kingsway, W.C., Chemical Apparatus Maker.
1886. Griffin, Martin L., Mechanicville, Saratoga Co., N.Y., U.S.A., Consulting Chemist.
1902. Griffiths, Manfred E., Temple Road, Stowmarket, Suffolk, Explosives Chemist.
1894. Griffiths, Thos., The Cedars, Clapham Common, S.W., Manufacturing Chemist.
1902. Grimwade, Wilfrid R., 335—343, Spencer Street, West Melbourne, Vic., Australia, Manufacturing Chemist.
O.M. Grimwood, R., 60, Woodland Rise, Muswell Hill Road, N., Analytical Chemist.
1900. Grimwood, Robt. G., 43, Leaside Avenue, Muswell Hill, N., Analytical Chemist.
O.M. Grindley, J., Upper North Street, Poplar, London, E., Tar Distiller.
1905. Grip, August E., 495, Columbia Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
1888. Gripper, Harold, Great Central Railway, Gorton, Manchester, Analytical Chemist.
1906. Groenewoude, Sidney H., 36, Grosvenor Road, Highbury, N., Analytical Chemist.
1897. Gronemeyer, Herman H., 315, Amesbury Avenue, Cleveland, Ohio, U.S.A., Chemical Superintendent.
O.M. Grossmann, Dr. J., Northern Assurance Buildings, Albert Square, Manchester, Consulting Chemist and Chemical Engineer.
O.M. Groves, C. E., F.R.S., 352, Kennington Road, London, S.E., Chemist (Thames Conservancy).
1903. Grundy, F. Barnes, Victoria Mills, Bredbury, near Stockport, Technical Chemist.
1888. Gudeman, Dr. Edw., 903, Postal Telegraph Building, Chicago, Ill., U.S.A., Chemist.
1906. Guess, Geo. A., c/o Cananea Consolidated Copper Co., Cananea, Sonora, Mexico, Chemist.
1898. Guest, Harry A., c/o Federal Lead Co., Flat River, Mo., U.S.A., Chemist.
1899. Guest, Edw. Graham, 5, Church Hill, Edinburgh, Cereals Chemist.
1899. Guild, Frank N., University of Arizona, Tucson, Arizona, U.S.A., Professor of Chemistry.
1906. Gulline, Percy, Merrimack Manufacturing Co., Lowell, Mass., U.S.A., Printworks Superintendent.
1905. Gummere, W., 125, East Hanover Street, Trenton, N.J., U.S.A., Chemist.
1904. Gundlach, Walter, 155, East 79th Street, New York City, U.S.A., Superintendent of Colour Works.
1905. Gundlich, Dr. Charles, c/o Thorium Chemical Co., Maywood, N.J., U.S.A., Technical Chemist.
1903. Gunn, Gilbert, 181, Bury New Road, Heywood, Lancs., Paper Mill Chemist.
1900. Günther, Chas. E., Liebig's Extract of Meat Co., Ltd., 4, Lloyd's Avenue, London, E.C., Merchant.
1902. Günther, Wm. J. W., c/o Colonial Sugar Refining Co., Ltd., 1, O'Connell Street, Sydney, N.S.W., Australia, Inspector.
1894. Gurney, J. Clare, Fundicion de Plomo de D. Miguel Zapata, Portman, Prov. de Murcia, Spain, Analytical Chemist.
1899. Gutcher, Wm., Singapore Oil Mills, Singapore, S.S., Superintendent Engineer.
1903. Guthrie, Alan, South End, Northallerton, Yorks, and (Journals) c/o Cooper, Allen and Co., Cawnpore, India, Leather Chemist.
1903. Guthrie, Alex., Inglewood, Eaton Road, Coventry, Manager.
1901. Guthrie, John M., 199, Ferry Road, Leith, N.B., Analytical Chemist.
1903. Guttmann, Dr. Leo F., College of the City of New York, New York City, U.S.A., Research Chemist.
1892. Guttmann, Oscar, 12, Mark Lane, London, E.C., Consulting Chemical Engineer, M.Inst.C.E.
1904. Gyr, Dr. K. H., Zug, Switzerland, Analytical Chemist.

H

1902. Haas, Herbert, Union Ironworks, San Francisco, Cal., U.S.A., and (Journals) c/o Compania Metallurgica de Torreon, Torreon, Coahuila, Mexico, Metallurgical Engineer.
O.M. Habirshaw, W. M., 341, Madison Avenue, New York City, U.S.A., Chemical Engineer.
1904. Hacking, D. H., Henfield House, Clayton-le-Moors, near Accrington, Lancs., Soap Manufacturer.
1883. Hacking, W. H., The Grange, Clayton-le-Moors, near Accrington.
1900. Haddock, Arthur G., 60, Highbury, Newcastle-on-Tyne, Technical Chemist.
1907. Haddock, Franklin, 27, Marion Street, West Lynn, Mass., U.S.A., Leather Manufacturer.
1898. Haddow, Geo., Parkview, Redding, Polmont Station, N.B., Chemist.
1887. Hadfield, R.A., Hecla Works, Sheffield; 28, Hertford Street, Mayfair, London, W., and (Journals) Parkhead House, Sheffield, Steel Founder.
1884. Hadkinson, F., Pamphila Oil and Soap Works, Mitylene, Mediterranean, Oil Refiner and Soap Manufacturer.
O.M. Hadkinson, R., Smyrna, Asia Minor, Oil Refiner.
1904. Hadley, Geo., 58, Halesowen Street, Blackheath, Staffs., Spelter Works Manager.
1906. Haefele, J. E., 44, Randolph Avenue, East Rutherford, N.J., U.S.A., Chemist.
1902. Haff, Max M., Laboratory, 188, Metcalfe Street, Ottawa, Canada, Chemist.
1906. Hagen, Dr. Carl, 47, Victoria Street, London, S.W., Representative of Du Pont Powder Co.
1887. Haig, Robert, Dallarfield, [illegible] Engineer.

1906. Haigh, S. Wilson, 4, York Street, Dewsbury, Yorks., Chemical Engineer.

1898. Haigh, De Lagnel, 22, Norwood Avenue, Summit, N.J., U.S.A., Chemist.

1883. Hailes, A. J. de, 15, Red Lion Square, London, W.C., Analytical Chemist.

1905. Haines, Harold W., 183, West 121st Street, New York City, U.S.A., Chemist.

1889. Haines, Reuben, Haines Street, near Chew Street, Germantown, Philadelphia, Pa., U.S.A., Analytical Chemist.

O.M. Hake, C. N., 423, Flinders Lane, Melbourne, Victoria, Australia, Inspector of Explosives.

1903. Halbert, Thos., c/o British South African Explosives Co., Modderfontein, Transvaal, Chemist.

1888. Hale, Edw. P., Endmoor, near Kendal, Analytical Chemist.

1903. Hale, Dr. Frank E., Mount Prospect Laboratory, Flatbush Avenue and Eastern Parkway, Brooklyn, N.Y., U.S.A., Chemist.

1887. Hall, Allan T., c/o Sissons Bros. and Co., Ltd., Hull, Oil Refiner and Varnish Manufacturer.

1905. Hall, Archibald A., Armstrong College, Newcastle-on-Tyne, Demonstrator in Chemistry.

1886. Hall, Archibald D., 7, Fenchurch Avenue, London, E.C., Analytical Chemist.

1898. Hall, Clarence A., 51, Allen Lane, Mount Airy, Philadelphia, Pa., U.S.A., Chemist.

O.M. Hall, Edgar, Silver Spur, Stanthorpe, Queensland, Australia, Technical Chemist.

1902. Hall, Henry, c/o Booth and Co., Irk Vale Works, Middleton, Lancashire, Dyer and Finisher.

1903. Hall, Jas. W., Bombay, Baroda and Central India Railway, Sabarmata, near Ahmedabad, India, Linseed Oil Mills Manager.

1885. Hall, Jno. A., Victoria Chemical Works, Victoria, British Columbia, Analytical Chemist.

1900. Hall, Jos. J., 810, Sixth Avenue East, Cedar Rapids, Iowa, U.S.A., Chemist.

O.M. Hall, S., East London Soap Works, Bow, London, E., Soap Manufacturer.

1896. Hall, S. Godfrey, East London Soap Works, Bow, E.; (Journals) 19, Aberdeen Park, Highbury, N., Soap Maker.

1886. Haller, Geo., Sussex House, 52, Leadenhall Street, London, E.C., Chemical Merchant.

1903. Haller, H. Loft, 26, Scale Lane, Hull, Analytical Chemist.

1895. Halliwell, Edw., c/o Ribble Joint Committee, 2, Stanley Place, Preston, Chief Inspector.

1900. Hallock, Dr. Albert P., 440, First Avenue, New York City, U.S.A., Chemist.

1892. Hamaguchi, K., Hiro Mura, Arito Gori, Wakayama Ken., Japan, Soy Manufacturer.

1904. Hamblet, Abel Martin, c/o Oxford Paper Co., Rumford Falls, Maine, U.S.A., Chemist.

1897. Hambly, Fred. J., Buckingham, Quebec, Canada, Chemist.

1901. Hambuechen, Carl, c/o Pittsburg Reduction Co., East St. Louis, Ill., U.S.A., Electro-Chemist.

1904. Hamilton, E. H., c/o Arizona Smelting Co., Humbolt, Arizona, U.S.A., General Superintendent.

1885. Hamilton, Oswald, Lancaster Cottage, Old Stratford, near Stony Stratford, Chemical Engineer.

1892. Hamilton, Robt., 40, Sefton Terrace, Beeston Hill, Leeds, Analytical Chemist.

1884. Hamilton, Robert, Glengarnock Chemical Co., Ltd., Glengarnock, N.B., Works Manager.

1903. Hammersley, W. Stanley, 15, Rue des Carriers, Soignies, Belgium, Tanner.

O.M. Hammill, M. J., The Gables, St. Helens, Alkali Manufacturer.

O.M. Hammond, J., Gas Works, Eastbourne, Sussex, Gas Manager.

1902. Hampson, B. A., Hampson's Collieries, Waschbank, Natal, S. Africa, Assayer.

1903. Hampton, F. T., Hill City, Tenn., U.S.A., Civil Engineer.

1906. Hancock, H. Irving, Blue Point, N.Y., U.S.A., Chemist.

1903. Hancock, Thos. J., c/o General Chemical Co., Hagemeyer, Ia., U.S.A., Chemist.

1906. Hancock, Walter C., 16, Upper Charlotte Street, Middleton Square, London, E.C., Chemist.

1896. Hand, Daniel, 30, Mount Pleasant Avenue, Newark, N.J., U.S.A., Chemist.

1899. Handy, Jas. O., 325, Water Street, Pittsburg, Pa., U.S.A., Chemist.

1888. Hanks, Abbot A., 2562, Washington Street, San Francisco, Cal., U.S.A., Assayer.

1901. Hanna, Charles E., P.O. Box 2302, Montreal, Canada, Secretary.

1899. Hanna, Dillinger C., 4262, Parkside Avenue, Philadelphia, Pa., U.S.A., Chemist and Superintendent.

1905. Hanna, W. W., 109, North Water Street, Philadelphia, Pa., U.S.A., Aniline Colour Manufacturer.

1905. Hanson, H. Norman, Field Head, Brighouse, Yorks., Research Assistant.

1905. Harcourt, Prof. R., Ontario Agricultural College, Guelph, Ont., Canada, Professor of Chemistry.

1904. Hard, Dr. James, M.B., Cordobanes 16, Mexico City, Mexico, Chemist and Pathologist.

1901. Hardcastle, G. Fred., 17, Chaucer Street, Leicester, Teacher of Science and Technology.

1894. Harden, Dr. Arthur, 2, Marlborough Road, Richmond, Surrey, Lecturer in Chemistry.

1900. Hardwick, W. Roscoe, 13, Batavia Buildings, Haskins Hey, Liverpool, Chemist.

1905. Hardy, Chas. H., c/o Reckitt & Sons, Ltd., Hull, Chemist.

1902. Hardy, G. D., 11, Montague Place, Toronto, Ont., Canada, Metallurgist.

1906. Hargreaves, Frank, c/o The Electrolytic Alkali Co., Ltd., Middlewich, Cheshire, Chemist.

1896. Hargreaves, Jas., May Villa, Peel House Lane, Widnes, Lancashire, Chemical Engineer.

O.M. Hargreaves, Jno., Widnes, Alkali Manufacturer.

1904. Harker, Dr. George, 35, Boulevarde, Petersham, Sydney, N.S.W., Australia, Chemist.

O.M. Harland, R. H., Plough Court, 37, Lombard Street, London, E.C., Consulting Chemist.

1904. Harley, B., 12, Russell Street, Falkirk, N.B., Analytical Chemist.

1893. Harlock, E. B., Newton House, Middlewich, Chemical Manufacturer.

1898. Harman, Edw. A., Gas Works, Huddersfield, Gas Engineer, M.Inst.C.E.

1905. Harper, Dr. Henry W., University of Texas, 2706, San Antonio Street, Austin, Texas, U.S.A., Professor of Chemistry.

1904. Harrington, Dr. B. J., University Library, McGill University, Montreal, Canada, Director.

1903. Harrington, E. M., 109, Broad Street, Woodbury, N.J., U.S.A., Explosives Manufacturer.

1905. Harrington, John H., 139, High Street, Perth Amboy, N.J., U.S.A., Chemist.

O.M. Harrington, W. B., Leeview, Montenotte, Cork, Ireland, Chemical Manufacturer.

1893. Harris, Arthur, 22, Marsh Gate Lane, Stratford, E., Soap Maker.

1885. Harris, Booth, jun., Beeleigh, Victoria Road, Barkhurst Hill, Essex, Soap Maker.

O.M. Harris, David, F.R.S.E., Lyncombe Bank, Prior Park Road, Bath, Chemical Manufacturer.

1897. Harris, Fred. W., Corporation Chemical Department, 26, John Street, Glasgow, Public Analyst.

1906. Harris, Jonathan, W., 259, South Clinton Street, Chicago, Ill., U.S.A., Chemist.

1900. Harris, L. A., Wyoming, Wood Vale, Leckhill Lane, London, S.E., Chemist.

1907. Harris, Thos. E., c/o The Union Acid Co., 17, Cooper Street, Manchester, Chemical Merchants.

1906. Harris, Wm. G., jun., 31, William Street, Toronto, Canada, Metallurgist.

O.M. Harrison, A., Thames Sugar Refinery, Silvertown, London, E., Sugar Works Chemist.

1905. Harrison, E. E., Langdale, Bowker Vale, Todmorden, South Croydon, Analytical Chemist.

1883. Harrison, G. Heather, Hagley, Stourbridge, Chemist.

1904. Harrison, H. E., 1668, Buckingham Place, Chicago, Ill., U.S.A., Chemist.
1892. Harrison, Prof. John B., C.M.G., 45, Westbourne Park Road, Bayswater, W., Government Analyst.
1896. Hart, Bertram, c/o Tennants and Co., Clayton, Manchester, Analyst.
1886. Hart, Bertram H., Rosslyn, High Street, Sidcup, Kent, Analytical Chemist.
O.M. Hart, Dr. E., Gayley Hall, Lafayette College, Easton, Pa., U.S.A., Professor of Chemistry.
1905. Hart, George Adam, Sewage Engineers' Office, Municipal Buildings, Leeds, Civil Engineer.
1890. Hart, H. W., 5, Cambridge Road, Ansdell, Lytham, Lancashire, Analytical Chemist.
1897. Hart, Wm. Beamont, Manchester Laboratory, 8, Exchange Street, Manchester, Consulting Chemist.
1883. Hartley, Joseph, 102, Kirkmanshulme Lane, Longsight, Manchester, Technical Chemist.
1889. Hartley, R. Kent, Springwood House, Middleton Junction, near Manchester, Chemical Works Manager.
O.M. Hartley, Prof. W. N., D.Sc., F.R.S., Royal College of Science, Dublin, Professor of Chemistry.
1897. Hartmann, Ernest E., c/o United Club, No. 4, Yokohama, Japan, Chemist.
1892. Hartridge, Jas. Hills, Holmwood, Hendon, N., Manufacturing Chemist.
1905. Hartshorne, Wm. D., 40, Pleasant Street; and (Journals) Arlington Mills, Methuen, Mass., U.S.A., Agent.
1905. Hartwell, F. O., c/o Holyoke Card and Paper Co., Springfield, Mass., U.S.A., Purchasing Agent.
1901. Hartwell, S. Warren, 215, North 2nd Street, Easton, Pa., U.S.A., Chemist.
1901. Hartzell, Harry S., 126, North 4th Street, Allentown, Pa., U.S.A., Chemist.
1899. Harvey, Chas., 17, Alloa Road, Goodmayes, Ilford, Essex, Manufacturing Chemist.
1892. Harvey, E. Feild, Omrac, St. John's, Newfoundland, Chemist.
1885. Harvey, Ernest W., Stoneleigh, Grove Road, Clapham Park, S.W., A.R.S.M., Engineer.
1891. Harvey, Sidney, South-Eastern Laboratory, Canterbury, Analytical Chemist.
1899. Harvey, Thos. F., 84, Henry Road, West Bridgford, Nottingham, Analyst (Drug Co.).
1883. Harvey, T. H., Cattedown, Plymouth, Chemical Manufacturer.
1903. Hasenclever, Max, Chemische Fabrik Rhenania, Aachen, Prussia, Chemical Manufacturer.
1906. Haskell, Walter F., 234, Bridge Street, Westbrook, Maine, U.S.A., Textile Chemist and Colourist.
1900. Haslwanter, Chas., 86, Pilling Street, Brooklyn, N.Y., U.S.A., Analytical Chemist.
1897. Hasslacher, Jacob, P.O. Box 1999, New York, U.S.A., President, Roessler-Hasslacher Chemical Co.
1903. Hasting, J. J., c/o Louis Leavitt, North 11th Street and Driggs Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1903. Hatschek, Emil, c/o S. Bornett and Co., Ltd., 19, St. Dunstan's Hill, London, E.C., Engineer.
1887. Hatton, Wm. P., c/o W. R. Hatton and Sons, Wormwood Scrubs, W., Starch Works Manager.
1906. Hattrick, J. M., 7, Bridge Street, Sydney, N.S.W., Australia, Agronom.
1900. Havens, Dr. F. S., 1434 Pine Street, Philadelphia, Pa., U.S.A., Silk Conditioner.
1906. Havercroft, Arthur E., 3, Carlton Terrace, Hornsea, Yorks, Chemist.
1899. Hawdon, H. S., Cleadon, near Sunderland, Manager.
1895. Hawker, E. W., Adelaide Club, Adelaide, South Australia, Metallurgist.
1902. Hawkins, Clement C., c/o The Chatfield Manufacturing Co., Carthage, Ohio, U.S.A., Chemist.
1897. Hawkins, Ernest M., Lime Tree Farm House, Stone Street, Petham, Canterbury, Chemist.
O.M. Hawkins, H., White's Farm, Gottenham, Chippenham, Wilts, Explosive Works Manager.
1905. Hawkins, Henry, Moyola Villa, Lisnadown, Limerick, Ireland, Gas Engineer.
1893. Hawkins, J. Dawson, c/o Colo. Phila. Reduction Co., Colorado City, Colo., U.S.A., Smelting Works Manager.
1905. Hawley, Fred G., Box 10, La Canasea, Sonora, Mexico, Assayer and Chemist.
1887. Hawliczek, Josef, 77A, Lord Street, Liverpool, Consulting Chemical Expert.
1899. Haworth, Dr. Edw., Sunnyside, Norman Road, Runcorn, Cheshire, Chemist.
1903. Haworth, Herbert, Crown Works, Appley Bridge, near Wigan, Director (Grove Chemical Co.).
1904. Hawthorn, J. H., Municipal Technical School, Leicester, Head Master.
1895. Hay, Alex. B., Kelvindock Chemical Works, Maryhill, Glasgow, Manufacturing Chemist.
1898. Haycraft, Jos. H., St. Peter's, Adelaide, South Australia, Metallurgical Chemist.
1904. Hayman, Jack V. J., Semper Aurea, Burwell, Cambridge, Chemist.
1894. Haynes, David O., 90, William Street, New York City, U.S.A., Proprietor, "Pharmaceutical Era."
1902. Hays, B. F., c/o E. R. Squibb and Sons, 80, Beekman Street, New York City, U.S.A., Chemist.
1906. Hayworth, W. P., 119, Clapton Common, London, N.E., Chemist.
1902. Hazard, Dr. Elmer C., Shrewsbury, N.J., U.S.A., Chemist.
1905. Hazard, Fred. R., P.O. Box 2, Syracuse, N.Y., U.S.A., President (Solvay Process Co.).
1903. Hazen, Chas. R., 106a Belmont Place, Westmount, Quebec, Canada, Chemist.
1894. Heal, Carlton, Duston, near Northampton, Chemist.
1903. Heald, Henry I., Hove House, Adwick Road, Mexborough, near Rotherham, Yorks, Manager of Earthenware Factory.
1890. Heape, Chas., 19, George Street, Manchester, Calico Printer.
O.M. Heath, R. C., Myton Grange, near Warwick, Chemical Manufacturer.
1905. Heathcote, Henry L., Warwick Avenue, Earlsdon, Coventry, Research Chemist.
1904. Heaton, Noel, 20, Baker Road, Harlesden, N.W., Colour Manufacturer.
1895. Hebden, Jno. C., P.O. Box 824, Providence, R.I., U.S.A., Works Manager and Chemist.
1905. Heberlein, Dr. Edw., c/o H. T. Enthoven & Sons, Ltd., 247, Rotherhithe Street, London, S.E., Works Manager.
1889. Hecht, Jos. L., Bettendorf Metal Wheel Co., Davenport, Iowa, U.S.A., Analytical Chemist.
1895. Hecker, Paul, 102, Fenchurch Street, London, E.C., Chemical Merchant.
1900. Heckman, J. Conrad, Larkin Soap Manufacturing Co., Seneca Street, Buffalo, N.Y., U.S.A., Chemist.
1889. Heckmann, C., 9, Görlitzerufer, Berlin, S.O., Germany, Chemical Apparatus Maker.
1885. Hedley, Armorer, Durrant House, Bournemouth, Hants.
1895. Hedley, Geo. H., Hedge Mill, Loudwater, Bucks., Chemical Manufacturer.
1902. Heebner, Prof. Chas. F., Ontario College of Pharmacy, Toronto, Canada, Professor of Pharmaceutical Chemistry.
1903. Hegeman, John W., 102, Barbey Street, Brooklyn, N.Y., U.S.A., Chemist.
1906. Hehner, Charles, c/o H. and A. Saunders, Eclipse Building, King Street, Toronto, Canada, Assistant Manager.
O.M. Hehner, Otto, 11, Billiter Square, London, E.C., Analytical and Consulting Chemist.
1902. Heike, Rudolph E., American Sugar Refining Co., P.O. Box L, Jersey City, N.J., U.S.A., Chemist.
1905. Heilborn, Jacob, 503, Washington Street, Brookline, Mass., U.S.A., Traveller.
1898. Hellaman, W. H., 2530, Regent Street, Berkeley, Cal., U.S.A., Expert Field Assistant.
1887. Hellier, E. A., Avonside Varnish Works, St. Philip's Marsh, Bristol, Varnish Manufacturer.
1885. Hellon, Dr. E., 40, New Lowther Street, Whitehaven, Analytical and Consulting Chemist.

O.M. Helps, H. J., 87, Hassocks Road, Bromley, Kent, Government Analyst.

1903. Helps, D. H., c/o Reading Gas Co., King's Road, Works, Reading, Engineer and Manager.

1903. Hemingway, Frank C. R., 132, Front Street, New York City, U.S.A.

1883. Hemingway, H., 6, Albemarle Mansions, Hampstead, N.W., Chemical Manufacturer.

1884. Hempleman, F. S., 39, Brunswick Terrace, Hove, Sussex, Manure Manufacturer.

1903. Hemstreet, George P., Hastings-on-Hudson, N.Y., U.S.A., Mechanical Engineer.

1883. Henderson, Prof. G. G., The Technical College, George Street, Glasgow, Professor of Chemistry.

1902. Henderson, Prof. Jas. A. Russell, Chihli Provincial College, Paotingfu, North China, Professor of Chemistry and Physics.

1900. Henderson, J. Brownlie, Government Analyst's Office, Brisbane, Queensland, Government Analyst.

1902. Henderson, J. C. A., 120, Bishopsgate Street Within, London, E.C.

1894. Henderson, Jos., Thornaby Ironworks, Thornaby-on-Tees, Metallurgical Chemist.

1894. Henderson, Norman M., Broxburn Lodge, Broxburn, N.B., Oil Works Manager.

1906. Henderson, Thos., 14, Dey Street, New York City, U.S.A., Manufacturing Chemist.

O.M. Henderson, W. F., Moorfield, Claremont Gardens, Newcastle-on-Tyne.

1893. Hendrick, Jas., Marischal College, Aberdeen, Lecturer on Agricultural Chemistry.

1906. Henius, Dr. Max, 327, Fullerton Avenue, Chicago, Ill., U.S.A., Secretary, Brewers' School.

1904. Henley, F. R., 9, Beaufort Gardens, London, S.W., Brewer's Chemist.

1889. Hannin, Alphonse, Portoferraio, Elba, Italy, Metallurgical Chemist.

1905. Henning, Albert, 92, Harrow Road, Leytonstone, N.E., Chemical Manufacturer.

1906. Henning, C. I. B., P.O. Box 42, Santa Cruz, Cal., U.S.A., Chemist.

1894. Henshaw, Sam., Glenthorne, Wolstanton, Stoke-on-Trent, Chemical Works Manager.

1894. Hepburn, J. G., Priory Works, Dartford, Kent, Leather Manufacturer.

1906. Herig, Harry W., 35, Rose Avenue, Jersey City, N.J., U.S.A., Chemist.

1891. Heriot, T. H. P., 37, Church Crescent, Muswell Hill, N., Analytical Chemist.

O.M. Herman, W. D., Holm Lea, Rainhill, Lancashire, Glass Works Chemist.

O.M. Heron, John, 110, Fenchurch Street, London, E.C., Brewing Chemist.

1903. Herreshoff, J. B. F., 40, West 69th Street, New York City, U.S.A., Chemical Engineer.

1899. Herrick, Rufus F., 16, Herrick Street, Winchester, Mass., U.S.A., Chemist.

1887. Herriot, Wm. Scott, Ravenswood, Partickhill, Glasgow, Mechanical Engineer.

O.M. Herrmann, R. W., 59, Mark Lane, London, E.C., Chemical Merchant.

1891. Hersam, Ernest A., University of California, Berkeley, Cal., U.S.A., Assistant Professor of Metallurgy.

O.M. Herschel, Prof. A. S., F.R.S., Observatory House, Slough, Bucks., Hon. Professor of Experimental Physics.

1896. Hersey, Milton L., P.O. Box 554, Montreal, Canada, Consulting Chemist.

1901. Hershey, Aldus N., c/o Sharpe and Dohme, Baltimore, Md., U.S.A., Chemist.

1903. Herstein, Dr. Bernard, 9a, Trask Avenue, Bayonne, N.J., U.S.A., Technical Chemist.

1906. Harty, Prof. Chas. H., University of N. Carolina, Chapel Hill, N.C., U.S.A., Professor of Chemistry.

1903. Herz, Dr. Albert, Rosemount, Hipperholme, Halifax, Yorks, Chemist.

1898. Herzog, Oliver, Fernholme, Prince's Road, St. Helens, Lancs., Analytical Chemist.

1895. Hess, Dr. Adolph, Kirkstall Road, Leeds, Chemical Manufacturer.

1904. Hess, H. W., c/o Libbey Glass Co., Toledo, Ohio, U.S.A., Chemist.

1905. Hesse, Dr. Bernhard C., 90, William Street, New York City, U.S.A., Chemist.

1891. Hetherington, Dr. Albert E., Ammonia Soda Works, Fleetwood, Lancashire, Analytical Chemist.

1904. Heurich, Christian, 1307, New Hampshire Avenue, N.W., Washington, D.C., U.S.A., Brewer.

1894. Hewitt, A. H., The Green Island Cement Co., Ltd., Hong Kong, China, and (Journals) Spring Vale, near Gurnard, Isle of Wight, Engineer.

O.M. Hewitt, Dr. D. B., Oakleigh, Northwich, Cheshire, Alkali Manufacturer.

1903. Hewitt, H. R., 329, Bradford Road, Manchester, Chemical Works Manager.

1896. Hewitt, Dr. J. Theo., 7, The Avenue, Surbiton, Lecturer.

1890. Hewlett, John C., 40-42, Charlotte Street, Great Eastern Street, London, E.C., Manufacturing Chemist.

1893. Hey, Harry, 2, Ash Terrace, Savile Town, Dewsbury, Dyer.

1905. Heymann, Dr. Fritz, (Journals) temporary, 83, Dorotheenstr., Berlin, N.W.; and 7, Elsworthy Terrace, Hampstead, N.W., Analytical Chemist.

1906. Heys, Charles H., 124, Yonge Street, Toronto, Canada, Consulting Chemist.

1884. Heys, W. E., Llanberis, Bushey Hall Road, Watford, Consulting Engineer.

1883. Heywood, J. H., 231, Drake Street, Rochdale, Technical Chemist.

1897. Hibbard, Paul L., 2657, North 42nd Court, Chicago, Ill., U.S.A., Starch Chemist.

1906. Hibbert, John C., 6, Victoria Road, West Bridgford, Nottingham, Chemist.

1901. Hiby, Dr. Walter, 4, Southampton Row, London, W.C., Chemical Engineer.

1906. Hicking, W. Norton, Queen's Road Works, Nottingham, Lace Dresser.

1906. Hickman, T. Moore, Holmdale, Penn Road, Wolverhampton, Analyst.

1897. Hicks, Edwin F., 4837, Fairmount Avenue, Philadelphia, Pa., U.S.A., Analytical Chemist.

1893. Hicks, Jas. A., c/o Dr. B. Redwood, 4, Bishopsgate Street Within, London, E.C., Analytical Chemist.

O.M. Higgin, W. H., Hollywood, Lostock, near Bolton-le-Moors, Chemical Manufacturer.

1886. Higgins, C. L., 79, Bedford Street South, Liverpool, Manufacturing Chemist.

1905. Higgins, Eric, 5, Oak Terrace, Beech Street, Liverpool, E., Chemist.

1905. Higgins, John M., 39, Queen Street, Melbourne, Vic., Australia, Consulting Metallurgist.

1901. Highley, Arnold, 26, Parkfield Avenue, Bradford Moor, Bradford, Chemist.

1904. Hildebrand, Charles C., Costello, Pa., U.S.A., Chemist.

1903. Hill, Chas. Alex., 64, Park Street, Southwark, S.E., Chemist.

1897. Hill, George, Barton-on-Humber, Chemical Works Manager.

1897. Hill, Dr. Herbert M., University of Buffalo, N.Y., U.S.A., Professor of Chemistry and Technology.

O.M. Hill, J. K., 13, Osborne Place, Copland Road, Govan, near Glasgow, Manufacturing Chemist.

1892. Hill, Sydney, Eastholme, Prince's Avenue, and (Journals) c/o Blundell, Spence & Co., Ltd., Hull, Analytical Chemist.

1903. Hill, W. Basil, James Street Leather Works, York, Tanner.

1902. Hill, Wm. G. H., jun., American Radiator Co., Cambridgeport, Mass., U.S.A., Chemist.

1898. Hill-Jones, Thos., Invicta Mills, East Greenwich Lane, London, E., Manufacturing Chemist.

O.M. Hills, C. H., Andrews Copper Works, Lemington, Newcastle-on-Tyne, Copper Smelter.

1894. Hills, Harold T., Commercial Gas Works, Stratford, London, E., Analytical Chemist.

O.M. Hills, W., 225, Oxford Street, London, W., Pharmaceutical Chemist.
1898. Hilton, Edgar G., 17, Howard Drive, Grassendale, Liverpool, Varnish and Paint Manufacturer.
1899. Hinchley, J. W., 15, Fawcett Street, London, S.W., Chemical Engineer.
1906. Hinckley, Everett H., Sayleaville, R.I., U.S.A., Foreman.
1904. Hinckley, J. F., c/o Jones Bros., Pearl and Water Streets, Brooklyn, N.Y., U.S.A., Chemical Engineer.
1905. Hind, H. Lloyd, 55, Stanton Road, Burton-on-Trent, Analytical Chemist.
O.M. Hindle, J. H., 8, Cobham Street, Accrington, Dyeworks Manager.
1899. Hinks, Percy J., Danger Building Dept., Royal Laboratory, Woolwich Arsenal, S.E., Chemist.
1891. Hinman, Bertram C., 48, Sydenham Hill, Sydenham, S.E., Metallurgical Chemist.
1892. Hinshelwood, Thos., Glasgow Oil and Paint Works, Glenpark Street, Glasgow, Oil Refiner.
1905. Hiorns, A. H., Caerleon, Chester Road, Erdington, near Birmingham, Science Teacher.
1900. Hirsh, Jos. E., 1245, 85th Street, Brooklyn, N.Y., U.S.A., Chemist.
1903. Hirshfield, E., c/o United Chemical Co., 52, Broadway, New York City, U.S.A., Chemist.
1895. Hirst, H. Reginald, Bank House, Staincliffe, Batley, Yorks., Works Chemist.
1886. Hislop, Geo. R., (Journals) Gas Works, (communications) Greenhill House, Underwood Road, Paisley, N.B., Gas Engineer and Manager.
1900. Hobbs, Alex. F., c/o The United States Finishing Co., Box A, North Station, Providence, R.I., U.S.A., Printworks Superintendent.
1900. Hobbs, Dr. Perry L., Western Reserve Medical College, Cleveland, Ohio, U.S.A., Professor of Chemistry.
1906. Hobsbaum, Isaac B., 79, Claremont Road, Forest Gate, E., Analytical Chemist.
1905. Hobson, Alfred, Dantzic Brewery, Imperial Street, Regent Street, Leeds, Brewer and Wine Manufacturer.
1904. Hochstetter, Henry, Ault and Wiborg Co., Cincinnati, Ohio, U.S.A., Chemist.
1894. Hodge, Andrew, Dalmonach Works, Bonhill, Dumbartonshire, Printworks Chemist.
1890. Hodges, Harry B., Long Island Railroad Co., Long Island City, N.Y., U.S.A., Chemical Engineer.
O.M. Hodgkinson, Dr. W. R., 18, Glenluce Road, Blackheath, S.E., Professor of Chemistry.
O.M. Hodgson, Chris., 33, Oakdale Road, Nether Edge, Sheffield, Metallurgical Chemist.
1897. Hodgson, Matthew, Ardmore, Wicklow, Ireland, Technical Chemist.
1905. Hodgson, T. R., 23, Aberdeen Road, Highbury, N.
1890. Hodgson, Wm., 66, Deansgate, Manchester, Oil and Colour Broker.
1903. Hoffmann, W. F., 23, Division Place, Newark, N.J., U.S.A., Chemical Merchant.
1906. Hogarth, Julius W., 37, Annandale Street, Sydney, N.S.W., Australia, Demonstrator of Chemistry.
1896. Hogben, W., 9, Duddingston Crescent, Portobello, Edinburgh, Chemist.
O.M. Hogg, T. W., c/o John Spencer and Sons, Newburn Steelworks, Newcastle-on-Tyne, Metallurgical Chemist.
1905. Holcroft, Harold, Parkdale, Wolverhampton, Ironfounder.
1903. Holde, Dr. D., Königl. Materialprüfungsamt, Grosser Lichterfelde, W., Germany, Principal.
1899. Holden, Archie Neill, c/o Hardman and Holden, Ltd., Miles Platting, Manchester, Chemist.
1903. Holden, G. E., 23, Durnford Street, Middleton, near Manchester, Works Chemist.
1887. Holden, G. H., Manchester Oxide Co., Ltd., Canal Street, Miles Platting, Manchester, Chemist.
1904. Holden, Norman K., c/o Hardman and Holden, Ltd., Colliery Lane, Clayton, Manchester, Manufacturing Chemist.
1902. Holdsworth, Ernest T., 30, [illegible] Dyer.
1904. Holgate, Arthur, c/o Wm. [illegible] Earl Street, Liverpool, Corn Miller.
1885. Holgate, T. E., 173, Hollins Grove, [illegible] cashire, Metallurgist.
1884. Holgate, Thos., 5, Victoria Street, [illegible] S.W., Gas Engineer.
O.M. Holland, Philip, 22, Tavitton Street, Gordon Square, London, W.C., Analytical Chemist.
1892. Holland, Philip H., 546, Sherbrooke Street West, Montreal, Canada, Merchant.
1901. Hollick, Herbert, c/o General Chemical Co., Camden N.J., U.S.A., Works Manager.
1902. Holliday, Lionel B., Lunnclough Hall, Huddersfield Chemical Manufacturer.
1896. Hollings, J. Spencer, Yrondeg, near Wrexham North Wales, Works Manager.
1903. Hollinshead, Peter, 19, The Hollow Way, Runcorn Cheshire, Chemist.
1900. Hollinshead, Dr. W. H., Vanderbilt University Nashville, Tenn., U.S.A., Teacher of Chemistry
1904. Holloway, E. G., c/o Jas. S. Kirk and Co., Chicago Ill., U.S.A., Chemist.
1890. Holloway, G. T., 57-58, Chancery Lane, London W.C., Analytical and Consulting Chemist.
1900. Hollway, Jno., 6, Highbury Grange, London, N. and (Journals) c/o Wm. Galbraith, 97, William Street, Sheffield, Mine Owner.
1883. Holmes, Ellwood, Wynoote, Jesmond Park East Newcastle-on-Tyne, Colour Manufacturer.
O.M. Holmes, F. G., Northcroft, Tewitwell Road Harrogate, Yorks., Technical Chemist.
1907. Holmes, Wm. E., Trent Bridge Leather Works, and (Journals) 31, George Road, West Bridgford Nottingham, Chemist.
1900. Holthouse, Harold B., 12, Melton Grove, West Bridgford, Notts., Chemist.
1902. Holton, Alf. L., Chemical Dept., Gas Works Bradford Road, Manchester, Chemist.
1892. Holton, E. C., 601, Canal Road, S.W., Cleveland Ohio, U.S.A., Chemist.
1893. Holzapfel, Max, Milburn House, Newcastle-on-Tyne Manufacturer.
1893. Homfray, D., The Ings, Misterton, near Gainsborough, Analytical Chemist.
1905. Hook, Arthur Henry, Box 25, Greenwood, B.C. Canada, Chemist.
1904. Hooker, A. H., c/o Heath and Milligan Manufacturing Co., 170, Randolph Street, Chicago, Ill. U.S.A., Manufacturing Chemist.
O.M. Hooper, E. Grant, 16, Royal Avenue, Sloane Square, S.W., Chemist.
1889. Hooper, Ernest F., Wear Fuel Works, Hendon Dock Sunderland, Technical Chemist.
1888. Hope, Jas., Dean House, Lenzie, N.B., Nickel Works Manager.
1904. Hopewell, Fredk., 86, Youville Square, Montreal Canada, Manager.
1892. Hopkins, Erastus, Lake Helen, Fla., U.S.A., Consulting Chemist.
1894. Hopkins, Herbert W., (Journals) c/o Waihi G. M. Co., Waihi, Paeroa, N.Z.; and 13, Harrington Gardens, South Kensington, S.W., Metallurgist
1905. Hoppenstedt, A., W., 138, Joralemon Street Brooklyn, N.Y., U.S.A., Chemist.
1898. Hopwood, Wm. H., Lovenbank Cottage, Jamestown, Dumbartonshire, Printworks Chemist.
1895. Horne, Dr. W. D., 175, Park Avenue, Yonkers, N.Y., U.S.A., Consulting Chemist.
1904. Hornsey, J. W., 216, Prospect Street, Cranford, N.J., U.S.A., Chemical Engineer.
1900. Horsfall, Jno., 4, Grange Avenue, Fawtonside, Manchester, Analytical and Consulting Chemist.
1902. Horsfall, L. H., c/o Binny and Co., Madras, India Chemist.
1901. Horton, Edw., jun., 10, Smith Square, Clapham, S.W., Student.
1906. Hosmann, Jas. H., Sun Building, [illegible] Manchester, Chemical Manufacturer.

[illegible]

1906. [illegible], Chemist, Rosetta Park, Belfast, Ireland.

1[illegible]. [illegible], M., 31, South Clark Street, [illegible], U.S.A., Chemist.

1905. [illegible], Frederick M., 902, Rialto Building, St. [illegible], Mo., U.S.A., Attorney-at-Law.

1899. Howard, Herman E., 80, Lady Margaret Road, Southall, Middlesex, Chemist.

1893. Howarth, John, 26, Princess Street, Manchester, Dyemaker.

O.M. Howard, A. G., Burnt House, Chigwell, Essex, Chemical Manufacturer.

1901. Howard, Bernard F., Quintocks, Montalt Road, Woodford Green, Essex, Chemist.

O.M. Howard, D., Devon House, Buckhurst Hill, Essex, Chemical Manufacturer.

1887. Howard, D. Lloyd, City Mills, Stratford, E., Chemical Manufacturer.

1903. Howard, Fred. A., 254, Montello Street, Brockton, Mass., U.S.A., Chemist.

1898. Howard, Henry, Dymoke Street, Brookline, Mass., U.S.A., Chemical Engineer.

1902. Howard, Nelson A., c/o General Chemical Co., Hegewisch, Ill., U.S.A., Chemist.

1904. Howard, T., c/o Williams Bros. and Co., Hounslow, Chemist.

O.M. Howard, W. D., City Mills, Stratford, London, E., Chemical Manufacturer.

1906. Howe, Chester A., 124, Purchase Street, Boston, Mass., U.S.A., Dyestuff Merchant.

1903. Howe, Jas. Lewis, Washington and Lee University, Lexington, Va., U.S.A., Professor of Chemistry.

1905. Howe, Roland E., 196, Commonwealth Avenue, Concord Junction, Mass., U.S.A., Explosives Chemist.

1904. Howell, Walter L., Appraiser's Office, Custom House, New Orleans, La., U.S.A., Chemist.

1906. Howland, George W., 293, Dufferin Street, Toronto, Canada, Manager.

1899. Howles, Fred., c/o McDougall Bros., Millwall Docks, London, E., Chemist.

1889. Howorth, F. Wise, 46, Lincoln's Inn Fields, W.C., Technical Chemist and Chartered Patent Agent.

1906. Hoyler, Fritz, 49, Market Street, Perth Amboy, N.J., U.S.A., Chemist.

1894. Hoyte, Percy S., Gas Works, Coxside, Plymouth, Gas Engineer.

1900. Hübner, Julius, Ash Villa, Cheadle Hulme, Cheshire, Director of Dyeing and Papermaking Departments (Municipal School of Technology).

1898. Hudson, Albert W., Rigby Mining and Reduction Co., Mayer, Ariz., U.S.A., Metallurgist.

1902. Hudson, C. Edward, c/o E. G. Jepson and Co., Albion Walk Chambers, Leeds, Drysalter.

1899. Hudson, Dr. Edw. J., c/o Pioneer Iron Co., Marquette, Mich., U.S.A., Chemist.

1905. Hudson, C. F., The University, Edgbaston, Birmingham, Lecturer on Metallurgy.

O.M. Hughes, J., 79, Mark Lane, London, E.C., Agricultural Chemist.

1898. Hughes, Raymond M., Oxford, Butler Co., Ohio, U.S.A., Professor of Chemistry and Physics.

1900. Hulley, Geo. D., c/o J. Eavenson and Sons, Delaware Avenue and Penn Street, Camden, N.J., U.S.A., Soapworks Chemist.

1906. Hulme, Robert B., c/o Kentucky Refining Co., Louisville, Ky., U.S.A., Chief Chemist.

1903. Hulton, H. F. E., 11, Colinette Road, Putney, S.W., Chemist.

1906. Hunal, Edward J., 7912, Grace Avenue, S.W., Cleveland, Ohio, Chemist.

1903. Humbray, Chas., Hilderstone, Hartford, Cheshire, Alkali Works Manager.

1901. Humphrey, H. C., c/o Corn Products Refining Co., Room 1202, 90, Broadway, New York City, U.S.A., Chemist.

1[illegible]. [illegible], John, 79, Great Russell Street, London, W.C., [illegible] Technological Record, [illegible].

1903. Humphrey, Hugh L., U.S. [illegible], Exposition Grounds, St. Louis, Mo., U.S.A., Civil Engineer.

1903. Humphreys, A. C., 31, Nassau Street, New York City, U.S.A., Engineer.

O.M. Humphrys, N. H., Gasworks, Salisbury, Wilts, Gas Engineer.

1895. Hunicke, Dr. H. Aug., 3522, Victor Street, St. Louis, Mo., U.S.A., Prof. of Applied Chemistry.

1900. Hunt, Arthur V., 284, New Chester Road, Port Sunlight, Cheshire, Analytical Chemist.

O.M. Hunt, Bertram, 121, West George Street, Glasgow, Technical Chemist.

O.M. Hunt, Chas., 15, Victoria Street, Westminster, London, S.W., Gas Engineer.

1883. Hunt, J. S., Appleton, Widnes.

1903. Hunt, P. C. Holmes, Metropolitan Gas Co., Flinders Street, Melbourne, Vic., Australia, Gas Engineer.

O.M. Hunt, W., Hampton House, Wood Green, Wednesbury, Staffordshire, Chemical Manufacturer.

1903. Hunter, H. B., Dennery Factory, St. Lucia, West Indies, Sugar Works Manager.

1902. Hunter, Hy. Blount, Hunter Chemical Co., Norfolk, Va., U.S.A., Industrial Chemist.

1893. Hunter, Prof. Matthew, Cowside, Settle, Yorks, Professor of Chemistry.

O.M. Huntington, Prof. A. K., King's College, Strand, London, W.C., Professor of Metallurgy.

1902. Huntly, Geo. N., 96, Gower Street, London, W.C., Analytical and Consulting Chemist.

1904. Huntzinger, Alfred, Route de Condette, Pont de Briques, Pas de Calais, France, Chemist and Colourist.

1903. Hurlburt, Allen S., c/o General Chemical Co., Hudson River Works, Hudson Heights, N.J., U.S.A., Chemist.

1904. Hurren, F. H., 31, Melville Road, and (Journals) c/o The Rover Co., Ltd., Coventry, Analytical Chemist.

1894. Hurry, E. H., Goodwyns, Haslemere, Surrey, and (Journals) The Red House, Broadstairs, Mechanical Engineer.

O.M. Huskisson, P. L., 77, Swinton Street, London, W.C., Chemical Manufacturer.

O.M. Huson, C. W., 18, Batavia Buildings, Hanover Hill, Liverpool, Analytical Chemist.

1894. Hutcheson, Jno. F., 22, St. Enoch Square, Glasgow, Chemical Manufacturer.

1906. Hutchings, W. Maynard, Easedale, Elmfield Road, Gosforth, Newcastle-on-Tyne, Metallurgist.

O.M. Hutchinson, C. C., 3, Harcourt Buildings, Temple, E.C., Barrister-at-Law and Chemical Engineer.

1900. Hutchinson, E. George, Gas Works, Stockport, Gas Engineer.

O.M. Hutchinson, T. J., Aden House, Manchester Road, Bury, Analytical and Consulting Chemist.

1901. Hutton, Dr. Robt. S., The University, Manchester, Lecturer on Electro-Chemistry.

1906. Hutton, James S., 61, Plymouth Road, Malden, Mass., U.S.A., Chemist.

O.M. Huxley, Jas. H., c/o Vickers, Son and Maxim, Ltd., River Don Works, Sheffield, Metallurgical Chemist.

1906. Huyett, Miles C., 1203, Traders Bank Building, Toronto, Canada, Mechanical Engineer.

1897. Hyams, Godfrey M., 312, Sears Building, Boston, Mass., U.S.A., Mines Manager.

1902. Hyde, Austin T., P.O. Box 93, Rumford Falls, Maine, U.S.A., Chemical Engineer.

1897. Hyde, B. T. Babbitt, 80, West Street, New York City, U.S.A., Soap Manufacturer.

1899. Hyde, Fred. S., 215, Schermerhorn Street, Brooklyn, N.Y., U.S.A., Research Chemist.

1899. Hyde, Wm. Greatley, 26, Whitefriars Street, Fleet, Common, S.W., Analyst.

1901. Hyman, Leonard W., 501, South [illegible], Albany, N.Y., U.S.A., Analytical Chemist.

1896. Hyndman, W. F., Rosslyn, 27, Ravenscroft Road, Kensington, W., Consulting [illegible].

1898. Ibbotson, E. C., Gysinge, Sweden, Metallurgist.
1900. Ichioka, Tajiro, 19, Maruyama Shinmachi, Hongo, Tokio, Japan, Chemist (Imperial Japanese Navy).
1906. Iddings, Richard P., Arlington Mills, Lawrence, Mass., U.S.A., Chemist.
1885. Idris, T. H. W., M.P., 120, Pratt Street, Camden Town, N.W., Mineral Water Manufacturer.
1902. Ihart, John P., 373, West 35th Street, New York City, U.S.A., Technical Chemist.
1900. Imrie, John, 415, Shields Road, Glasgow, Analytical Chemist.
1906. Ingalls, Robert C., 53, Commercial Street, West Lynn, Mass., U.S.A., Sales Manager.
1900. Ingalls, Walter R., (Communications) 505, Pearl Street, New York City; and (Journals) Bement Avenue, West New Brighton, Staten I., N.Y., U.S.A., Mining Engineer and Metallurgist.
1889. Ingle, Dr. Harry, Creskeld, Balwearie Road, Kirkcaldy, Fifeshire, Organic Chemist.
1891. Ingle, Herbert, Dept. of Agriculture, Government Buildings, Pretoria, Transvaal, Chemist.
1906. Inglis, Dr. Jno. K. H., University College, Reading, Berks, Lecturer.
1884. Inglis, R. A., Culrain, Bothwell, N.B., Analytical Chemist.
1906. Innes, Dr. W. Ross, 6, Griffiths Road, Wimbledon, S.W., Chemist.
1904. Irlam, H. A., Cleveden, Hightown Road, Luton, Beds., Manager and Chemist.
1884. Irving, J. M., 17A, Dickinson Street, Cooper Street, Manchester, Chemical Merchant.
1906. Irwin, John T., Cledford, Middlewich, Cheshire, Manufacturing Chemist.
O.M. Irwin, W., Inglehurst, Stand, near Manchester, Analytical Chemist.
1893. Isaac, J. F. V., Research Chemist.
1896. Isaacs, Louis A., 110, Greencroft Gardens, West Hampstead, N.W., (Journals) c/o Yeatman and Co., Ltd., Denmark Street, E., Manufacturer.
1901. Isakovics, Alois von, Synfleur Scientific Laboratories, Monticello, N.Y., U.S.A., Manufacturing Chemist.
1900. Ittner, Dr. Martin H., c/o Colgate and Co., Jersey City, N.J., U.S.A., Soap and Essential Oil Chemist.

J

1890. Jackman, E. J., 60, Belgrave Road, Ilford, Essex, Technical Chemist.
1898. Jackson, Alf. George, 65, Ann Street, Brisbane, Queensland, Electro-Chemical Engineer.
1906. Jackson, Arthur A., 672, East 43rd Street, Chicago, Ill., U.S.A., Chemist.
1901. Jackson, Daniel D., Mount Prospect Laboratory, Flatbush Avenue and Eastern Parkway, Brooklyn N.Y., U.S.A., Chemist.
1903. Jackson, Dr. D. H., 73, Parliament Hill, Hampstead, N.W., Chemist.
O.M. Jackson, Edward, Ravens Clift, Oxford Road, Moseley, Birmingham, Alkali Works Inspector.
1904. Jackson, Ernest W., 11, Queen's Terrace, Middlesbro', Analytical Chemist.
1891. Jackson, F., Smedley Bridge Works, Cheetham, near Manchester, Bleacher and Dyer.
1883. Jackson, Frederick, 14, Cross Street, Manchester. Laboratory Furnisher.
1886. Jackson, John, 98, Dobbie's Loan, Glasgow, Lubricant Manufacturer.
1901. Jackson, Percy G., Chemical Laboratory, Locomotive Dept., Midland Railway, Derby, Chemist.
O.M. Jackson, R. V., c/o Scotch and Irish Oxygen Co., Polmadie, Glasgow, Technical Chemist.
1890. Jackson, Saml., c/o H. S. Duncan, Roundhay, Harrington's Road, Chetput, Madras, India, Analytical Chemist.
1902. Jackson, Samuel, c/o Wm. Metcalf, Ltd., Church, near Accrington, Director (Tar Distillery).
1898. Jackson, Thos., Clayton Chemical Works, Clayton, Manchester, Chemical Manufacturer.
1900. Jackson, Victor G., 21, Frankfort Road, Herne Hill, S.E., Chemist.
1901. Jackson, W. B., Glengowan Printworks, Caldercruix, N.B., Chemist.
1903. Jackson, Wm. D. N., 291, Station Road, Wallsend-on-Tyne, Analytical Chemist.
1900. Jackson, Dr. W. Hatchett, Radcliffe Library, Oxford, Librarian and Science Tutor (Keble College).
1893. Jackson, Rt. Hon. W. L., F.R.S. *See* Allerton, Rt. Hon. Lord.
1899. Jackson, W. Morton, c/o Manchester Oxygen Co., Ltd., Great Marlborough Street, Manchester, Manager.
O.M. Jackson, W. P., Saxilby, near Lincoln, Chemical Works Manager.
1901. Jacobs, Charles B., 52, Beaver Street, New York City, U.S.A., Chemist.
1901. Jacobsen, Rudolph C., 154, Lake Street, Chicago, Ill., U.S.A., Editor of "Hide and Leather."
1900. Jacoby, Areli H., c/o American Dyewood Co., 156, William Street, New York City, U.S.A., Chemist.
1897. Jacqué, Maurice, "La Cantabrica," Galdacano, cerca Bilbao, Spain, Chemical Engineer.
1901. Jadhava, Khasherao B., Nausori, Bombay, India, Collector and District Magistrate.
1900. Jäger, B. M., c/o Geo. Jäger and Sons, 77, Burlington Street, Liverpool, Sugar Chemist.
1886. Jago, Wm., 5, Fig Tree Court, Temple, London, E.C., Barrister-at-Law.
1889. James, Alf., 2, Broad Street Place, London, E.C., Mining Engineer.
1883. James, E. T., British Alizarin Co., Ltd., Silvertown, Victoria Docks, E., Secretary.
1885. James, Dr. J. Wm., Aylmer House, Weston-super-Mare; and (Journals) 29, Redcliff Street, Bristol, Chemical Lecturer.
1893. James, Lawrence S., 32, Hawley Street, Boston, Mass., U.S.A., Gas Inspector.
1905. James, Oscar S., 227, George Street, Toronto, Canada, Analytical Chemist.
1902. Jameson, Lewis, 83, Queen Victoria Street, London, E.C., Consulting Chemist.
1903. Janes, Frank W., Wolseley Street, Surrey Hills, Victoria, Australia, Assayer.
1890. Jantzen, Paul, 133, Fenchurch Street, London, E.C., Chemical Merchant.
O.M. Japp, Dr. F. R., F.R.S., The University, Aberdeen, Professor of Chemistry.
1906. Jardine, Samuel, c/o Dallyn, Jardine and Co., 23, Scott Street, Toronto, Canada, Chemical Merchant.
1890. Jarmain, Geo. S., Dalton Lodge, Huddersfield, Wool Extractor.
O.M. Jarmay, G., Hartford Lodge, Hartford, Cheshire, Alkali Manufacturer.
1900. Jarvie, Jas., Monkland House, Kirkintilloch, N.B., Chemist.
O.M. Jayne, Dr. H. W., 931, North Broad Street, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
O.M. Jekyll, J., Castle Moat House, Lincoln, Chemical Manufacturer.
1892. Jenkin, W. A., 5, Bella Vista, Minas de Rio Tinto, Provincia de Huelva, Spain, Metallurgical Chemist.
1905. Jenkins, Chas. D., 8, Grove Street, Winchester, Mass., U.S.A., Chemist.
1894. Jenkins, John H. B., Laboratory, G.E.R. Works, Stratford, E., Analytical Chemist.
1894. Jenks, Robt. L., Central Excise Laboratory, Kasauli, Punjab, India, Chemist.
1905. Jennison, Jas., 103, Lynwood Avenue, Darwen, Lancashire, Chemist.
1904. Jepson, John Elliott, The Star Paper Mill Co., Ltd., Feniscowles, near Blackburn, Chemist.
1899. Jerdan, Dr. David S., c/o J. and G. Cox, Ltd., Gorgie Mills, Edinburgh, Chemist (Gelatni Works).

99. Jessop, Louis V., Holmlea, Woodville Road, Leytonstone, Essex, Chemist.
04. Jessup, Alfred E., Tientsin, North China, Assayer.
04. Jewell, Wm. M., Cable Building, Chicago, Ill., U.S.A., Chemist and Engineer.
04. Jewson, F. T., Thornly Park Terrace, Paisley, N.B., Chemist.
06. Job, Robt., 109, Windsor Street, Reading, Pa., U.S.A., Analytical Chemist.
06. John, David, Haileybury, Ontario, Canada, Chemist.
86. Johnson, A. E., Claremont, Lyndhurst Road, Wolverhampton, Analytical Chemist.
04. Johnson, Cedric, Field House, Winnington, Northwich, Chemical Engineer.
06. Johnson, Chas. C., Vandreuil Station, Quebec, Canada, Chemical Engineer.
05. Johnson, Chas. F., Avery Chemical Co., Littleton, Mass., U.S.A., Superintendent.
02. Johnson, Chas. M., 701, Orchard Street, Avalon, Allegheny Co., Pa., U.S.A., Chemist.
91. Johnson, Edmond E., The Gales, Roding Lane, Woodford Bridge, Essex, Chemical Engineer.
00. Johnson, Edw., c/o Herdeiros Bowman, Ltd., Caixa 57, Pernambuco, Brazil, Sugar Works Manager.
02. Johnson, Emil F., 96–98, Maiden Lane, New York City, U.S.A., Consulting Chemist.
00. Johnson, F. Carter, National Acid Co., 714, Union Street, New Orleans, La., U.S.A., Chemical Engineer.
04. Johnson, F. M. G. (Journals), 286, Peel Street, Montreal, Canada; and (communications) University College, London, W.C., Chemist.
04. Johnson, G. B., 7, Church Street, Liverpool, Wholesale Chemist.
06. Johnson, Dr. Harold, 5 and 6, Fowkes' Buildings, Great Tower Street, London, E.C., Chemist.
07. Johnson, H. Finnis, c/o Borax Consolidated, Ltd., 16, Eastcheap, London, E.C., Sales Manager.
03. Johnson, Horace, Waialua, Oahu, Hawaii, Chemist.
.M. Johnson, J. E., 40, Idmiston Road, Stratford, E., Manufacturing Chemist.
95. Johnson, Jesse F., Vaudreuil Station, P.Q., Canada Chemical Engineer.
84. Johnson, J. Grove, 23, Cross Street, Finsbury, E.C., Assayer.
00. Johnson, John, c/o John Johnson and Co., Franklin Square, New York City, and (Journals) 1336, 53rd Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
00. Johnson, Jno. W. H., York House, Thornhill, Dewsbury, and (Journals) West Riding Rivers Board, Wakefield, Yorks., Chemist.
06. Johnson, Oliver L., c/o The Aspinook Co., Jewett City, Conn., U.S.A., Dye Works Manager.
.M. Johnson, S. H., Warren Hill House, Loughton, Essex, Chemical Engineer.
04. Johnson, S. Hearon, 7, Church Street, Liverpool, Wholesale Chemist.
.M. Johnson, T. A., Field House, Winnington Park, Northwich, Cheshire.
03. Johnson, Thos., Caixa 94, Pernambuco, Brazil, Manager.
95. Johnston, Alex. R., 18, Percy Street, Ibrox, Glasgow, Analytical Chemist.
06. Johnston, A. McA., Box 108, Germiston, Transvaal, Metallurgical Chemist.
94. Johnston, G. Lawson. *See* Lawson-Johnston, G.
04. Johnston, J. H., 8, Leopold Road, Wimbledon, S.W., Chemist and Bacteriologist.
89. Johnston, Thos., Nobel's Explosives Co., Ltd., 195, West George Street, Glasgow, Manager.
04. Johnston, Thos. J., 4, Garrioch Drive, Kelvinside North, Glasgow, Chemist.
80. Johnston, Wm. A., The S. S. White Dental Manufacturing Co., Princess Bay, Staten Island, N.Y., U.S.A., Dental Enamel Manufacturer.
94. Johnston, W. E. Lawson. *See* Lawson-Johnston, W. E.
.M. Johnston, Wm. G., Anchor Chemical Works, 1005, Garngad Road, Glasgow, Technical Chemist.
.M. Johnstone, Jas., Shawfield Works, Rutherglen, Glasgow, Technical Chemist.
05. Johnstone, J. Swanston, National Distilleries Co., Bond Street, Durban, Natal, Distiller.
03. Johnstone, S. J., 15, Springfield Road, New Southgate, N., Research Chemist.
.M. Johnstone, W. G., 14, South Clerk Street, Edinburgh, Chemist.
05. Jolliffe, Frank, 60, Sandrock Road, St. John's, S.E., Chemist.
02. Jollyman, Walter R., P.O. Box 3782, Johannesburg, Transvaal, Analyst.
03. Jones, Alfred O., c/o Carr and Co., Caldewgate, Carlisle, Works Chemist.
04. Jones, Arthur B., c/o General Chemical Co., Station F, Box 12; and (Journals) 452, Russell Avenue, Cleveland, Ohio, U.S.A., Superintendent.
97. Jones, Chas. H., c/o Capillitas Copper Co., Muschaca, near Andalgala, Prov. Catamarca, Argentina, Technical Chemist.
02. Jones, David R., Standard Chemical Co., Deseronto, Ont., Canada, Chemical Engineer.
02. Jones, E. Strangways, Sulphide Corporation, Ltd., Cockle Creek, N.S.W., Australia, Metallurgical Chemist.
.M. Jones, E. W. T., 10, Victoria Street, Wolverhampton, Analytical Chemist.
97 Jones, Fred. W., 18, Warren Road, Chingford, Essex, Explosives Works Manager and Chemist.
96. Jones, G. Cecil, Stour Villa, Mistley, Essex, Brewer's Chemist.
04 Jones, G. Poole, c/o Sinnamahoning Powder Manufacturing Co., Emporium, Pa., U.S.A., Chemical Engineer.
03. Jones, G. Robert, Gas Works, Caixa 147, Pernambuco, Brazil, Gas Engineer.
05 Jones, Harold, Morro Velho, Villa Nova de Lima, Minas Geraes, Brazil, Analyst and Assayer.
.M. Jones, H. Chapman, Royal College of Science, South Kensington, S.W., Senior Demonstrator in Chemistry.
98. Jones, Henry, Broughton Bridge Mills, Salford, Dyer and Finisher.
93. Jones, Herbert. *See* Sefton-Jones, H.
01. Jones, Herbert J., c/o The Scottish Acid and Alkali Co., Ltd., Kilwinning, N.B., Chemist.
05. Jones, J. E. Stacey, Masonic Buildings, Coventry, Consulting Chemist and Metallurgist.
04. Jones, J. Shirley, Moscow, Idaho, U.S.A., Chemist.
99. Jones, Llewellyn J. W., Tacoma Smelting Co., Tacoma, Washington, U.S.A., Metallurgist.
98. Jones, Martin L., c/o Ooregum G. M. Co., Oorgaum, Mysore State, India, Metallurgical Chemist.
94. Jones, M. W., Greystonedale, Kensington Hill, Bristol, Manager (Oil and Colour Works).
87. Jones, T. Tolley, Australian Explosives and Chemical Co., Ltd., 138, Queen Street, Melbourne, Victoria, Australia, Explosives Manufacturer.
.M. Jones, Walter Norris, Lancashire Metal Works, Widnes, Technical Chemist.
03. Jones, Wm. App, c/o Boston Artificial Leather Co., Metropolitan Building, New York City, U.S.A., Chemist.
05. Jones, W. Ellis, 80, Arundel Avenue, Liverpool, Sugar Refiner.
05 Jones, W. H. Matthews, City Surveyor's Offices, The Town Hall, Chester, Deputy Surveyor.
09. Joplin, Geo. C., 12, Harrington Street, Sydney, N.S.W., Australia, Analyst.
04. Jordan, Stanley, 100, William Street, New York City, U.S.A., Importer of Chemicals.
97. Jorissen, Dr. Wm. P., Koninklijk Inst. v. d. Marine, Willemscoord, Holland, Editor.
05. Joseph, A. F., Royal College, Columbo, Ceylon, Lecturer on Chemistry.
00. Josephson, Edgar, 131, Amity Street, Brooklyn, N.Y., U.S.A.
06. Joshua, Dr. Walter P., 45, Belsize Avenue, Hampstead, N.W., Chemist.

1891. Joslin, Omar T., 3223, Spring Grove Avenue, Cincinnati, Ohio, U.S.A., Chemical Engineer.
1887. Joüet, Dr. C. H., Roselle, Union Co., N.J., U.S.A., Technical Chemist.
1889. Journand, Louis, Epaillage Chimique, Pont Evêque, près Vienne (Isère), France, Technical Chemist.
1904. Jowett, Dr. H. A. D., Phoenix Mills, Dartford, Kent, Chemist.
1903. Joyce, Clarence M., c/o Arlington Co., Arlington, N.J., U.S.A., Chemist.
1887. Jürgensen, Dr. Rolof, Karlsgasse 5, Prag-Zizkov, Austria, Chemist.
1900. Just, Jno. A., 915, West Genesee Street, and P.O. Drawer 40, Syracuse, N.Y., U.S.A., Chemist.
O.M. Justice, P. M., 55–56, Chancery Lane, London, W.C., Patent Agent.

K

1898. Kahn, Julius, 100, West 80th Street, New York City, U.S.A., Manufacturer of Rubber Goods.
1896. Kalbfleisch, Franklin H., Metropolis Building, Broadway and 16th Street, New York City, U.S.A., Chemical Manufacturer.
1884. Kalle, Dr. Wm., Biebrich-am-Rhein, Germany, Colour Manufacturer.
1907. Karp, Samuel E., 305, Franklin Avenue, Scranton, Pa., U.S.A., Chemist.
1905. Katzenbach, Welling S., 164, Front Street, New York City, U.S.A., Chemist.
1901. Kauder, Dr. E., c/o Merck and Co., Rahway, N.J., U.S.A., Chemist.
1903. Kauffman, Milton H., American Smelting and Refining Co., Durango, Colo., U.S.A., Chemist.
1892. Kaufmann, Dr. Herbert M., c/o Mutual Chemical Co., Jersey City, N.J., U.S.A., Chemist.
1904. Kaus, Dr. Emil, c/o Roessler and Hasslacher Chemical Co., Perth, Amboy, N.J., U.S.A., Chemist.
1904. Kawai, I., Camphor Monopoly Bureau, Kumoidori, Kobé, Japan, Chemist.
1885. Kawakita, Prof. Michitada, Imperial Engineering College, Tokio, Japan, Professor of Applied Chemistry.
O.M. Kay, Wm., E., Marple Lodge, Marple, Cheshire, Printworks Chemist.
1905. Kaye, Frederick, Hampden House, Phœnix Street, London, N.W., Research Chemist.
1904. Kaye, Thos., Westerfield, Perth, Scotland, Analytical Chemist.
1905. Kayser, Edwin Cuno, c/o Messrs. J. Crosfield & Sons, Ltd., Warrington, Chemist.
1884. Keane, Dr. Chas., A., Sir John Cass Technical Institute, Jewry Street, Aldgate, E.C., Principal.
O.M. Kearns, H. W., Baxenden House, near Accrington, Dyer.
1897. Kearns, Jno. S., Baxenden House, near Accrington, Chemist and Dyer.
1894. Kebler, Lyman F., Department of Agriculture, Bureau of Chemistry, Washington, D.C., U.S.A., Chief of Drug Laboratory.
1906. Keily, C. L., c/o Ilford, Ltd., Ilford, Essex, Chemist
1886. Keiser, Prof. E. H., Washington University, St. Louis, Mo., U.S.A., Professor of Chemistry.
1905. Keith, Simeon C., jun., 20, Highland Avenue, Somerville, Mass., U.S.A., Chemist and Bacteriologist.
1900. Kelf, Henry C., c/o Martineau's Brewers' Sugar Co., King Edward Street, London, E., Sugar Chemist.
1907. Keller, Dr. Edward, P.O. Box 724, Baltimore, Md., U.S.A., Chemist and Metallurgist.
1905. Keller, Robt. J., c/o Geigy Aniline & Extract Co., 69, Barclay Street, New York City, U.S.A., Dyestuff and Chemical Merchant.
1885. Kellner, Dr. Wm., 135, Victoria Road, Old Charlton, S.E., Chemist to War Department.
1889. Kempson, John F., Pye Bridge Chemical Works, near Alfreton, Derbyshire, Chemical Manufacturer.
1901. Kennedy, Alex., Kenmill House, Bothwell, N.B., Rosin Distiller.
1903. Kennedy, Hugh Watson, 626, South 19th Street, Philadelphia, Pa., U.S.A., Chemist.
1901. Kenrick, Dr. Frank B., 73, Baldwin Street, Toronto, Canada, Lecturer on Chemistry.
1903. Kenyon, Percy S., Park House, Cheadle Hulme, Cheshire, Drysalter.
1889. Kenyon, Thos., The Shrubbery, Hilton Park, Prestwich, near Manchester, Manufacturing Chemist.
1906. Kepner, S. H., 149, 12th Street, Long Island City, N.Y., U.S.A., Superintendent.
1900. Keppelmann, Alf. J., P.O. Box 1382, Philadelphia, Pa., U.S.A., Chemical Merchant.
1888. Ker, Alan D., 14, Wilton Mansions, Glasgow, Chemical Manufacturer.
1899. Kern, Walter P., 343, Lafayette Avenue; and (Journals) c/o General Chemical Co., Dundee Works, Passaic, N.J., U.S.A., Chemist.
1906. Kerr, Charles H., 525, Jefferson Avenue, Niagara Falls, N.Y., U.S.A., Ceramic Engineer (Carborundum Co.).
1894. Kerr, Jas., Surgeons Hall, Edinburgh, Lecturer on Chemistry.
1890. Kerr, Saml. T., 516, North Delaware Avenue, Philadelphia, Pa., U.S.A., Salt Manufacturer.
1897. Kerr, Wm. M., c/o General Chemical Co., 608, Philadelphia Bourse, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1896. Kershaw, Jno. B. C., West Lancashire Laboratory, Waterloo, Liverpool, Analytical Chemist.
1902. Kessler, Henry W., 317, Electric Building, Cleveland, Ohio, U.S.A., Manufacturing Chemist.
1903. Kessler, R., jun., The Nordmont Chemical Co., Nordmont, Pa., U.S.A., Chemical Manager.
1893. Kestner, Paul, 7, Rue de Toul, Lille, France, Chemist.
1898. Keswick, Wm., M.P., 3, Lombard Street, London, E.C., Merchant.
1900. Kewley, Jas., Arbory Road, Castletown, Isle of Man, and (Journals) Balek Pappan, Dutch Borneo, Technical Chemist.
1890. Keys, W. H., Lyndon House, West Bromwich, Oil and Chemical Manufacturer.
1892. Kibble, W. Oakes, Charlotte, N.C., U.S.A., Chemical Engineer.
1896. Kier, Thos., Thornliebank, Glasgow, Chemist.
1900. Kilgore, Benj. W., Raleigh, N.C., U.S.A., Chemist.,
1901. Kilmer, Fred. B., New Brunswick, N.J., U.S.A., Chemical Manufacturer.
1905. Kimball, Herbert S., 101, Tremont Street, Boston, Mass., U.S.A., Mill Engineer.
O.M. Kinch, E., Royal Agricultural College, Cirencester, Professor of Chemistry.
1905. King, Capt. Alex E., R.A., Egyptian Army Citadel, Cairo, Egypt, Inspector of Explosives.
O.M. King, A. J., M.P., (Journals) Ingersley Vale, and (communications) Rock Bank, Bollington, near Macclesfield, Bleacher and Finisher.
1884. King, Col. C. M., Campsie Alum Works, Lennoxtown, N.B., Alum Manufacturer.
1905. King, Frank E., 75, Gracechurch Street, London, E.C., Analytical Chemist.
O.M. King, J. Falconer, 20, Chambers Street, Edinburgh, Consulting Chemist.
1887. King, Col. Robt., 115, Wellington Street, Glasgow, Chemical Manufacturer.
1907. King, Robt. J., c/o Merrimac Chemical Co., North Woburn, Mass., U.S.A., Chemist.
1895. King, Sidney J., 1, Russell Villas, Pope's Grove, Strawberry Hill, Middlesex, Colour and Dyestuff Traveller.
O.M. King, Walter R., 16, Mincing Lane, London, E.C., and (Journals) Holford Lodge, Trinity Avenue, Southend-on-Sea, Chemical Manufacturer.

1905. King, Warren, C., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Salesman.
1903. King, William, c/o Natal Estates, Ltd., South Coast Junction, Natal, S. Africa, Analytical Chemist.
1899. King, Wm. R., 17, Fernwood Road, Summit, N.J., U.S.A., Mechanical Engineer.
1896. Kingdon, Holman, 25, Grappenhall Road, Stockton Heath, Warrington, Technical Chemist.
1883. Kingsford, T. P., Oswego, N.Y., U.S.A., Starch Manufacturer.
O.M. Kingzett, C. T., 1, Hornton Street, Kensington, W., and (Journals) Sanitas Co., Ltd., Locksley Street, Limehouse, E., Technical Chemist.
1906. Kinnersley, H. W., c/o Blyth and Platt, Solar Works, Watford, Herts, Chemist and Manufacturer.
1892. Kinnicutt, Professor L. P., 77, Elm Street, Worcester, Mass., U.S.A., Professor of Chemistry (Worcester Polytechnic Institute).
1897. Kipping, Dr. F. Stanley, F.R.S., University College, Nottingham, Prof. of Chemistry.
1906. Kirby, Oswald F., Leeds Institute, Leeds, Lecturer on Chemistry.
1898. Kirkland, Archd., 78, High Street, Irvine, N.B., Baker.
1905. Kirkland, John, 105, Holmdene Avenue, Herne Hill, S.E., Technical Instructor.
1897. Kirkland, Robt., 25, Collier Road, Cambridge, Chemist.
1905. Kirkman, A. S., 52, Bridge Street, Brooklyn, N.Y., U.S.A., Soap Manufacturer.
1900. Kirkpatrick, Prof. Stafford F., School of Mining, Kingston, Ont., Canada, Professor of Metallurgy.
1887. Kitamura, Y., Kaigun Kosho, Yokosuka, Japan, Agricultural Chemist.
1902. Kitchen, Wm. J., Port Melbourne North, Vic. Australia, Soap and Candle Manufacturer.
1891. Kitson, Rt. Hon. Sir James, Bart., M.P., Gledhow Hall; and (Journals) Monkbridge Iron and Steel Co., Ltd., Leeds, Iron and Steel Manufacturer.
1883. Kitto, B., 26, Lancaster Road, Finsbury Park, London, N., Analytical Chemist.
1900. Kittredge, H. G., 217, North Ludlow Street, Dayton, Ohio, U.S.A., Chemist.
1900. Kleber, Dr. Clemens, Union Avenue, Clifton, N.J., U.S.A., Director (Fritzsche Bros.' Laboratory).
1888. Kleemann, Dr. S., Farben Fabrik, Forchheim, Bavaria, Analytical Chemist.
1903. Kline, Clarence M., 429, Arch Street, Philadelphia, Pa., U.S.A., Wholesale Druggist.
1889. Klipstein, A., 122, Pearl Street, New York City, U.S.A., Chemical Manufacturer.
1902. Klipstein, Ernest C., 116, Prospect Street, East Orange, N.J., U.S.A., Chemical Manufacturer.
1907. Klotz, John R. McPherson, 26, State Street, Newark, N.J., U.S.A., Industrial Chemist.
1891. Knaggs, Alfred B., Bradley Lane, Huddersfield, Technical Chemist in Dyeworks.
1905. Knapp, Sewell A., 1243, Myrtle Street, Oakland, Cal., U.S.A., Mine Manager.
1906. Knapp, Walter R., c/o Semet Solvay Co., Ensley, Ala., U.S.A., Chemist.
1892. Knecht, Dr. E., Beech Mount, Marple, Cheshire. Professor of Tinctorial Chemistry.
1904. Kniffen, Frederick, c/o International Smokeless Powder Co., Parlin, N.J., U.S.A., Chemist.
1887. Knight, A. H., 2, Gerald Road, Oxton, Cheshire, Assayer.
1903. Knight, Harley F., 64, Amhurst Park, Stamford Hill, N., Analyst.
1884. Knight, Henry, Stanley House, 73, Anfield Road, Liverpool, Colour and Varnish Manufacturer.
O.M. Knight, J. Baillie, Royal Primrose Soapworks, Silvertown, London, E., Soap Manufacturer.
1887. Knights, J. West, Public Laboratory, Tenison Road, Cambridge, Analytical Chemist.
1885. Knipier, F., c/o R. Harper and Co., Port Melbourne, Victoria, Australia, Starch Manufacturer.
1883. Knowles, Joshua, Stormer Hill, Tottington, near Bury, Calico Printer.
1904. Knowles, W. Ra The Hollies, Wood Green, Wednesbury, Chemical Works Manager.
1886. Knox, E. W., Colonial Sugar Refining Co., Sydney, N.S.W.; and c/o Parbury, Henty and Co., 20, Eastcheap, London, E.C., Sugar Manufacturer and Refiner.
1902. Knudsen, Hans, 68, Victoria Street, London, S.W., Inventor.
1906. Knudson, Kristian Hv., 226, Willoughby Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1905. Koch, Geo. W., Look Box 12, Woodhaven, Long Is., N.Y., U.S.A., Chemist.
1904. Koch, J. A., Bluff and Pride Streets, Pittsburg, Pa. U.S.A., Chemist.
1903. Koch, Walter E., 527, Guaranty Trust Building, El Paso, Texas, U.S.A., Metallurgical and Mining Engineer.
1904. Koebig, Dr. J., 127, West First Street, Los Angeles, Cal., U.S.A., Chemical Engineer.
1901. Koehler, Dr. H., c/o Roessler and Hasslacher Chemical Co., Perth Amboy, N.J., U.S.A., Manager.
1904. Koerner, H. Theo., Beyerstrasse 28, Chemnitz, Germany, Student of Chemistry.
1884. Kohn, Dr. Charles A. *See* Keane, Dr. Chas. A.
1902. Kohnstamm, Lothair S., 87, Park Place, New York City, U.S.A., Chemist.
1904. Korte, Dr. R. F., Schwarzenstein, Altena i/Westfalen, Germany, Chemist.
1902. Kottmann, Dr. Gustav, Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Analytical Chemist.
O.M. Kraftmeier, E., 54, Parliament Street, Westminster, S.W., Explosives Manufacturer.
1906. Krais, Dr. Paul, 60, Nauclerstrasse, Tuebingen, Germany, Chemist.
1894. Krause, Dr. Albert H., 32, Wellington Avenue, Cleveland, Ohio, U.S.A., Chemist (Grasselli Chemical Co.).
O.M. Krause, Prof. Dr. G., Cöthen (Anhalt), Germany, Chemist.
O.M. Krause, O. H., c/o American Sugar Refining Co., Jersey City, N.J., U.S.A., Chemical Engineer.
1898. Krebs, H. J., 806, Franklin Street, Wilmington, Del., U.S.A., Manufacturing Chemist.
1900. Kremers, Dr. Edw., Madison, Wis., U.S.A., Professor (University of Wisconsin).
1906. Kremers, William, Holland, Mich., U.S.A., Sugar Mill Superintendent.
1904. Kübler, Alfred, 69, Barclay Street, New York City, U.S.A., Vice-President, Geigy Aniline and Extract Co.
O.M. Kühl, W. H., 73, Jägerstrasse, Berlin, Germany, Bookseller.
1900. Kunheim, Dr. Erich, 32, Dorotheenstrasse, Berlin, N.W., Germany, Chemist.
1904. Kunz, Dr. George F., c/o Tiffany and Co., 37th Street and 5th Avenue, New York City, U.S.A., Gem Expert.
1905. Kurt, Franklin T., 458, Boylston Street, Boston, Mass., U.S.A., Professor of Chemistry, B.Y.M.C.A.
1900. Kuttroff, Fred., 128, Duane Street, New York City, U.S.A., Merchant.
O.M. Kynaston, J. W., 3, Oak Terrace, Beech Street, Liverpool, Chemical Engineer.

L.

1897. Labonde, Dr. Leon, 145, West Adams Street, Los Angeles, Cal., U.S.A., Consulting Chemical Engineer.
1906. Lacell, Harold G., Marlowes, Hendon Lane Finchley, N., Chemist.
1890. Lacey, E. C., 10, Clarence Road, Croydon, Manufacturing Chemist.
1903. Lachman, Dr. Arthur, Petaluma, Cal., U.S.A. Chemical Engineer.

O.M. Laidler, C. P., 20, Noble Terrace, Gateshead-on-Tyne, Analytical Chemist.
O.M. Lake, G. jun., Lee Mount, Glossop, Derbyshire, Analytical Chemist.
1907. Lake, Henry B., Laboratory, Canadian Pacific Railway Co., Winnipeg, Canada, Chemical Engineer.
1900. Lamar, Wm. R., Mallinckrodt Chemical Works, St. Louis, Mo., U.S.A., Chemist.
1898. Lamb, Morris Chas., 151, Westcombe Hill, Blackheath, S.E., Chemist.
1900. Lambert, Walter S., Vardre Road, Clydach, R.S.O., Glamorgan, Analyst.
1907. Lancaster, Harry M., School of Practical Science, Toronto, Canada, Chemist.
1895. Lancaster, Jno. C., 260, Alfreton Road, Nottingham, Engineering Works Manager.
1904. Lancey, Darragh de, c/o Waterbury Buckle Co., Waterbury, Conn., U.S.A., Secretary.
1895. Landin, John, 40, Drottninggatan, Stockholm, Sweden, Public Analyst.
1904. Lane, C. Cyril P., c/o The Avon India-Rubber Co., Melksham, Wilts., Chemist.
1906. Lane, Fred H., 418, Sackett Street, Brooklyn, N.Y., U.S.A., Chemist.
1903. Lane, Nathaniel J., U.S. Laboratory, 641, Washington Street, New York City, U.S.A., Chemist.
1890. Lang, Jas. G., P.O. Box 475, Victoria, B.C., Canada, Analytical Chemist.
1893. Lang, Dr. Wm. R., University of Toronto, Canada, Professor of Chemistry.
O.M. Langdon, Dr. M. J., Room 511, 621, Broadway, New York City, U.S.A., Analytical Chemist.
1890. Lange, Dr. Martin, Malapani, bei Oppeln a/Schl, Germany, Analytical Chemist.
1892. Langer, Dr. Carl, Ynyspenllwch, Clydach, R.S.O., Glamorganshire, Analytical Chemist.
1897. Langmuir, Arthur C., c/o Marx and Rawolle, 9, Van Brunt Street, Brooklyn, N.Y., U.S.A., Factory Manager.
1902. Langmuir, F. Leighton, 350, Bloor Street West, Toronto, Canada, Chemist.
1898. Langstaff, Wm., Grasselli, N.J., U.S.A., Chemist.
1900. Lant, Herbert, "Ivy Bank," Wath-on-Dearne, near Rotherham, Yorks., Chemist and Manager.
1905. La Pierre, Elie H., 588, Huron Avenue, Cambridge, Mass., U.S.A., Pharmacist.
1906. Larsen, Axel, 76, York Street, Westminster, S.W., Mining Engineer.
1903. Larter, Alfred T., Coolavin, St. Stephen's Road, Hounslow, Chemist.
1907. Laschè, Prof. Alfred, The Laschè Institute, 2809, Vine Street, Milwaukee, Wis., U.S.A., Chemist and Bacteriologist.
1904. Lasher, F. G., The Lake Pigment Co., Dunellen, N.J., U.S.A., Chemist.
1884. Latham, Baldwin, Parliament Mansions, Victoria Street, Westminster, S.W., Civil Engineer.
1889. Latham, J. J., Mill House, Bold, Widnes, Chemical Works Manager.
1907. Lathwood, Arthur, c/o Borax Consolidated, Ltd., 16, Eastcheap, London, E.C., Chemist.
1904. Laury, N. Arthur, c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemist.
1906. Lautz, Alfred, 115, Rue des Poissonniers, St. Denis sur Seine, France, Colour Works Manager.
1904. Law, Herbert, 72, Belvedere Road, Liscard, Cheshire, Analytical Chemist.
O.M. Lawrence, Jas., Box 737, Joplin, Mo., U.S.A., Explosives Manufacturer.
1906. Lawrence, V. O., 801, Drexel Building, Philadelphia, Pa., U.S.A., Chemical Works Manager.
1904. Lawson, Jos. H. S., Britannia Mills, Hulme, Manchester, Salesman.
1900. Lawson, Wm., c/o Great Western Sugar Co., Sterling, Colo., U.S.A., Chemist.
1894. Lawson-Johnston, G., (Journals) 29, Portman Square, W., and c/o Bovril, Ltd., 152, Old Street, London, E.C., Vice-Chairman.
1894. Lawson-Johnston, W. E., c/o Bovril, Ltd., 152, Old Street, London, E.C., Director.
1893. Lawton, Thos., Calthorpe House, Aldridge Road, Perry Bar, Birmingham, Chemical Works Manager.
1905. Laycock, Thos. P., Fletton Spring, Peterborough, Managing Director, Platico Mantle Co.
1890. Laycock, Dr. W. F., 46, Boar Lane, Leeds, Analytical Chemist.
1902. Lazell, Ellis Warren, 42, North 16th Street, Philadelphia, Pa., U.S.A., Chemist.
1898. Lean, Geo., 15, Park Terrace, Glasgow, Chemist.
1897. Leathart, Thos. H., c/o Locke, Blackett and Co., Ltd., Lead Works, Newcastle-on-Tyne, Lead Manufacturer.
O.M. Leather, Dr. J. Walter, Agricultural Research Institute, Pusa, Bengal, India, Government Chemist.
1893. Le Boutillier, Clement, c/o Taylor Iron and Steel Co., High Bridge, N.J., U.S.A., Chemist.
1904. Le Chatelier, Prof. H., 75, Rue Notre Dame des Champs, Paris, France, Professor (l'Ecole des Mines).
1896. Lecomber, W. G., Cambridge Works, Knott Mill, Manchester, Engineer.
1896. Lederle, Dr. E. J., 518, Fifth Avenue, New York City, U.S.A., Chief Chemist.
1892. Ledoff, Prof A., Technological Institute, Kharkoff, Russia, Professor of Chemistry.
1895. Ledoux, Dr. Albert R., 99, John Street, New York City, U.S.A., Chemist.
1903. Ledoux, Aug. D., 68, Beaver Street, New York City, U.S.A., Importer of Pyrites.
1905. Lee, Ashton, Lawrence, Mass., U.S.A., Manufacturing Chemist.
1901. Lee, FitzHugh, c/o Grasselli Chemical Co., Cleveland, Ohio, U.S.A., Superintendent.
1905. Lee, Frank W., Lawrence, Mass., U.S.A., Manufacturing Chemist.
1905. Lee, John C., Mountford Street, Brookline, Mass., U.S.A, Assistant Engineer (American Telegraph and Telephone Co.).
1898. Lee, Jno. L., Woodfield, Lytham, Lancashire, Dyer and Bleacher.
1885. Lee, S. Wright, 6–10, Whitechapel, Liverpool, Wholesale Druggist.
1906. Lee, William, 43, Daisy Bank, Heaton Park, Manchester, Works Chemist.
1886. Leeds, F. H., 26, East Bank, Stamford Hill, N., Analytical Chemist.
1903. Leerburger, Henry, 54, Beekman Street, New York City, U.S.A., Essential Oil Merchant.
1903. Leese, Jos., jun., 3, Ash Grove, Victoria Park, Manchester, Analytical and Technical Chemist.
1901. Lefebvre, Georges, Compagnie du Phospho-Guano, 27 Rue La Rochefoucauld, Paris, Director.
1901. Leffler, Rudolf L., c/o Thos. Firth and Sons, Ltd., Norfolk Works, Sheffield, Metallurgical Chemist.
1907. Lehmann, Dr. Adolf, Bangalore, India, Agricultural Chemist.
1901. Leibfried, Jno. E., Bethlehem, Pa., U.S.A., Analytical Chemist.
1888. Leigh, Cecil, Birmingham Metal and Munition Co., Adderley Park Rolling Mills, Birmingham, Technical Chemist.
1906. Leigh, Edw. Collier, Caixa 147, Pernambuco, Brazil, Gas Works Manager.
1902. Leighton, A. E., Cordite Factory, Aruvankad, Nilgiris, India; and Journals (until May 31st only) to Whitcott, Edgware, Middlesex, Analytical Chemist.
1894. Leitch, Jno. W., Milnsbridge Chemical Works, near Huddersfield, Aniline Dye Manufacturer.
1904. Le Maistre, Fred J., Eastern Laboratory, Chester, Pa., U.S.A., Research Chemist.
1898. Leman, Wm. T., c/o The Texas Co., Port Arthur, Tex., U.S.A., Oilworks Manager.
1901. Lengfeld, Dr. Felix, 1804, Fillmore Street, San Francisco, Cal., U.S.A., Manufacturing Chemist.
1883. Lennard, F., c/o Forbes, Abbott & Lennard, Ltd., Chemical Works, Shoreham, Sussex, Chemical Manufacturer.

884. Leonard, Wm. J., 1, Lindfield Gardens, Hampstead, N.W., Naphtha Distiller.
903. Lepsius, Prof. Dr. B., Griesheim a/M., Germany, Director (Chem. Fabr. Griesheim-Elektron).
888. Lequin, E., Directeur Général des Usines de Produits Chimiques de la Société de St. Gobain, 1, Place des Saussaies, Paris (VIII'.), France.
904. Lesley, R. W., Pennsylvania Building, Philadelphia, Pa., U.S.A., Cement Manufacturer.
907. Leslie, Fred A., College of Pharmacy, 115, West 68th Street, New York City, U.S.A., Assistant Chemist.
894. Leslie, Hugh M., Mattikuppam, Mysore State, South India, Chemical Engineer.
904. Lessing, Dr. Rudolf, 3, Moriston Place, Clydach, R.S.O., Glam., Chemist.
900. Lessner, Chas. B., Carrill, Spain, Metallurgical Chemist.
892. Lester, J. H., Royal Exchange, Manchester, Analytical Chemist.
904. Le Sueur, E. A., 50, MacLaren Street, Ottawa, Ont., Canada, Electrical and Chemical Engineer.
899. Le Sueur, Dr. Henry R., Chemical Laboratory, St. Thomas' Hospital, London, S.E., Demonstrator.
898. Leuthardt-Thornton, Peter, 14, Steele's Road, Hampstead, N.W., Chemical Manufacturer.
891. Lever, Wm. H., M.P., Thornton House, Thornton Hough, Cheshire, Soap Manufacturer.
901. Levett, Walter, Holmlands, Stanford-le-Hope; and (Journals) Mines Safety Explosives Co., Stanford-le-Hope, Essex, Factory Manager.
903. Levi, Dr. Louis E., c/o Pfister and Vogel Leather Co., Milwaukee, Wis., U.S.A., Chemist.
906. Levinstein, Edgar, 74, India Street, Boston, Mass., U.S.A., Chemical Manufacturer.
901. Levinstein, Dr. Herbert, 21, Minshull Street, Manchester, Chemist.
O.M. Levinstein, Ivan, Hawkesmoor, Fallowfield, Manchester, Colour Manufacturer.
903. Levy, Arthur G., 45, Clifton Hill, Abbey Road, London, N.W., Chemist.
901. Levy-Mond, Dr. Albert, Brimsdown Works, Ponders End, Middlesex, Chemical Engineer.
905. Lévy, René J., c/o Soc. l'Air Liquide, 43, Rue St. Lazare, Paris, Chemist and Technical Manager.
887. Lewes, Prof. Vivian B., Royal Naval College, Greenwich, S.E., Professor of Chemistry.
898. Lewin, H. James, Royal Victoria Yard, Deptford, S.E., Analytical Chemist.
889. Lewis, A. E., 20, Seymour Street, Broadgreen, near Liverpool, Analytical Chemist.
896. Lewis, Daniel C., c/o Millville Manufacturing Co., Millville, N.J., U.S.A., Dye Works Chemist.
904. Lewis, Edw. W., c/o J. G. Ingram and Son, London India Rubber Works, Hackney Wick, N.E., Chemist.
900. Lewis, Ernest A., 310, Dudley Road, Birmingham, Chemist and Metallurgist.
905. Lewis, F. W., Aetna Powder Co., 1718, Tribune Building, Chicago, Ill., U.S.A., Secretary.
900. Lewis, John, 35, Mundania Road, Honor Oak, S.E., Cashier (Paint Works).
900. Lewis, S. Judd, 122, Newington Causeway, London, S.E., Analytical Chemist.
889. Lewkowitsch, Dr. Julius, 71, Priory Road, West Hampstead, N.W., Consulting Chemist.
901. Lichtenstein, Alf. F., c/o Geisenheimer and Co., P.O. Box 994, New York City, U.S.A., Chemist.
O.M. Lichtenstein, Theodore, Chemical Works, Silvertown, E., Manufacturing Chemist.
904. Lichtenthaeler, Robt. A., 303, South Main Street, Winston-Salem, N.C., U.S.A., Chemist.
892. Liddle, G. A., Fyreton Terrace, Crosby, Isle of Man, Chemist, Dyewood Extract Works.
885. Liddle, W. T., 14, Willows Avenue, Anadell, Lytham, Chemist and Manager.
904. Lieber, Hugo, 1, Platt Street, New York City, U.S.A., Chemist.
O.M. Liebmann, Dr. A., 16, Darby Avenue, West Didsbury, Manchester, Analytical Chemist.
899. Liedbeck, P. F. Marik, 43, Strandwagen, Stockholm, Sweden, Chemical Engineer.
O.M. Lightfoot, T. E., 88, Arden Terrace, Accrington, Calico Printer's Chemist.
905. Liley, Thos. A., 37, Aston Road, Bramley, Leeds, Chemist.
898. Lilly, Josiah K., c/o Eli Lilly and Co., Indianapolis, Ind., U.S.A., Manufacturing Pharmacist.
885. Lilly, Oliver M., The Croft, Spondon, Derby, Colour Manufacturer.
904. Lindemann, Ottocar, 53, Victoria Street, Westminster, S.W., Managing Director (Korting Bros., Ltd.).
906. Linder, S. E., Leodholt, The Drive, Buckhurst Hill, Essex, Analytical Chemist.
903. Lindmueller, C., c/o United Zinc and Chem. Co., Argentine, Kansas, U.S.A., Chemist.
897. Lindsay, Robt., Cyanide Works, Ferreira Deep G. M. Co., P.O. Box 1056, Johannesburg, Transvaal, Chemist.
890. Ling, Arthur R., Laboratory, 74, Great Tower Street, E.C.; and (Journals) Hazeldene, Kingston Road, New Malden, Consulting Chemist.
901. Lippincott, Warren B., c/o United Zinc and Chemical Co., Argentine, Kansas, U.S.A., Chemist.
905. Lips, Dr. Carl H., 99, Hart Street, Brooklyn, N.Y., U.S.A., Chemist.
896. Lishman, Geo. P., Bunker Hill, Fence Houses, Co. Durham, Colliery Chemist.
905. Little, Arthur D., 93, Broad Street, Boston, Mass., U.S.A., Consulting Chemist.
901. Little, C. A., Elyria, Ohio, U.S.A., Analytical Chemist.
889. Little, Wm. G., Blendon Grove, Bexley, Kent, Chemical Manufacturer.
O.M. Littlejohn, Jas., c/o Littlejohn and Whitby, P.O. Box 849, Johannesburg, Transvaal, Analytical Chemist.
904. Livermore, W. D., Washington Mill, Lawrence, Mass., U.S.A., Chemist.
886. Liversedge, A. J., c/o Fullerton, Hodgart & Barclay, Ltd., Vulcan Works, Paisley, N.B., Mechanical Engineer.
906. Liversedge, S. G., City Laboratory, Castle Street, Dublin, Ireland, Analytical Chemist.
904. Liversedge, J. F., Council House, Birmingham, Public Analyst.
O.M. Liversidge, Prof. A., F.R.S., The University, Sydney, N.S.W., Professor of Chemistry.
907. Liversidge, Bernard, Rossholme, Clifton Lane, Rotherham, Yorks, Analytical Chemist.
883. Livingston, W. J., London County Council, Spring Gardens, London, S.W., Analytical Chemist.
903. Llewellyn, Ivor P., Goole Alum Works, Goole, Chemist.
899. Lloyd, Charles, (subscriptions) c/o Lake View Consols, Ltd., Salisbury House, London, E.C.; and (Journals) c/o Manager, Lake View Consols, Ltd., Boulder, West Australia, Secretary.
900. Lloyd, Fred. J., Muscovy House, Trinity Square, London, E.C., Analyst.
904. Lloyd, Leonard B., Broadford Tannery, Broadford, Victoria, Australia, Tanner.
907. Lloyd, Dr. Lorenzo L., Technical College, Bradford, Yorks, Lecturer in Chemistry.
900. Lloyd, Thos. H., c/o Quibell Bros., Newark, Analyst.
901. Lober, Jno. B., Vulcanite Portland Cement Co., 1230, Land Title Building, Philadelphia, Pa., U.S.A., Cement Manufacturer.
888. Lodge, Edw., 25, Scale Hill, Cowcliffe, Huddersfield, Teacher of Wool Dyeing.
900. Loeb, Dr. Morris, 273, Madison Avenue, New York City, U.S.A., Professor of Chemistry.
891. Loewenthal, Dr. R., Uhlandstrasse 39, Frankfurt a/M., Germany, Lecturer on Dyeing.
905. Lomax, Abraham, 179, Lord Street, Farnworth, R.S.O., Potter's Chemist.
901. Long, Eugene J., c/o E. O'Callaghan and Son, City Tannery, Limerick, Ireland, Tanner.
898. Longstaff, Jas. P., Chemical Department, The University, Edinburgh, Assistant.

1904. Loomis, Dr. H., 58, West 40th Street, New York City, U.S.A.
1902. Loomis, Henry M., P.O. Box 185, Harrisburg, Pa., U.S.A., Chemist.
1890. Lord, F. J., 4, Winmarleigh Street, Warrington, Analytical Chemist.
1896. Lord, Jno. Lloyd, 23, Park View, Elton, Bury, Lancs., Chemist and Manager.
1897. Lord, N. W., 338, West 8th Avenue, Columbus, Ohio, U.S.A., Professor of Metallurgy.
O.M. Lorenz, H., 7 and 8, Idol Lane, London, E.C., Chemical Merchant.
1904. Lorimer, John H., 280, West Walnut Lane, Germantown, Philadelphia, Pa., U.S.A., Textile Machinist and Mercerisor.
1905. Loring, Lindley, 55, Kilby Street, Boston, Mass., U.S.A., Vice-President (Cochrane Chemical Co.).
O.M. Lorrain, J. G., Norfolk House, Norfolk Street, Strand, London, W.C., Chartered Patent Agent.
1904. Lossen, Dr. Clemens F., Strada Lipscani 10, Bukarest, Roumania, Chemist.
O.M. Lott, F. E., The Laboratory, Bridge Chambers, Burton-on-Trent, Consulting Brewing Chemist.
O.M. Louis, D. A., 77, Shirland Gardens, London, W., Metallurgist and Mining Engineer.
1894. Louis, Prof. Henry, Armstrong College, Newcastle-on-Tyne, Professor of Mining.
O.M. Love, Dr. E. G., 80, East 55th Street, New York City, U.S.A., Analytical Chemist.
1899. Love, Wm., 28, Royal Exchange Square, Glasgow, Managing Director (Broxburn Oil Co., Ltd.).
1895. Lovejoy, Frank W., Kodak Park, Rochester, N.Y., U.S.A., Chemical Engineer.
1904. Loveland, Jas. W., 8, Kenwood Street, West Somerville, Mass., U.S.A., Superintendent of Soap Works.
O.M. Lovibond, J. W., Lake House, Salisbury, Tintometer Manufacturer.
O.M. Lovibond, T. W., West Jesmond House, Newcastle-on-Tyne, Brewer.
1897. Low, Albert H., P.O. Drawer 1537, Denver, Colo., U.S.A., Metallurgical Chemist.
1900. Low, Prof. Wilson H., Cudahy Packing Co., South Omaha, Neb., U.S.A., Chemist.
1887. Lowe, Clement W., Thorneyholme, Knutsford, Cheshire, Manufacturing Chemist.
1905. Lowe, Houston, The Lowe Bros. Co., Dayton, Ohio, U.S.A., Paint and Varnish Maker.
1906. Lowe, James, City Chambers, 45, John Street, Glasgow, Gas Engineer.
1906. Lowe, Jos. A., Fitchburg, Mass., U.S.A., Paper Manufacturer.
O.M. Lowe, W. F., 9, Hough Green, Chester, Analytical Chemist.
1904. Lowenstein, Arthur, c/o Nelson, Morris and Co., U.S. Yards, Chicago, Ill., U.S.A., Chemist.
1885. Lowson, Dr. J. G. F., Snitterfield House, Stratford-on-Avon, Paper Maker.
1906. Lowson, Wm., The University, Leeds, Chemical Lecturer.
1895. Lucas, Alf., Survey Department, Giza, Egypt, Analyst.
1892. Lucas, Bernard R., Winnington Park, Northwich, Alkali Works Manager.
O.M. Lucas, R., Alwinenstrasse 11, Wiesbaden, Germany, Technical Chemist.
O.M. Luck, A. Courtenay, Naval Arsenal, Zarate, Argentina, Explosives Chemist.
1900. Lummus, Walter E., 62, Newhall Street, Lynn, Mass., U.S.A., Manager (Commonwealth Manufacturing Co.).
1903. Lumsden, Alex. A., Forth Chemical Works, Bo'ness, N.B., Technical Chemist.
1888. Lund, Jas., 142, Hawthorne Street, Malden, Mass., U.S.A., Ammonia Works Manager.
1888. Lundholm, Carl O., Nobel's Explosives Co., Ltd., Ardeer Factory, Stevenston, Ayrshire, Manager.
1898. Lundteigen, Andreas, Union City, Mich., U.S.A., Chemist.
O.M. Lunge, Prof. Dr. G., Rämistrasse 56, Zürich, V., Switzerland, Professor of Chemistry.
1894. Lungwitz, Theo., c/o Chas. Pfizer and Co., 81, Maiden Lane, New York City, U.S.A., Chemist.
1885. Lupton, Sydney, 102, Park Street, Grosvenor Square, London, W.
1890. Luthy Edmund O., 2419, Ohio Avenue, Cincinnati, Ohio, U.S.A., Distiller.
1884. Lüthy, Otto, Maywood, N.J., U.S.A., Analytical Chemist.
1895. Luxmoore, Dr. Chas. M., University College, Reading, Lecturer on Chemistry.
1899. Luxton, Thos., 28, Albany Street, Hull, Teacher of Chemistry.
1903. Lye, Ernest B., Leagrave Hall, near Luton, Beds., Straw Plait Dyer and Bleacher.
1885. Lye, W. T., Leagrave Hall, near Luton, Beds., Straw Dyer.
1884. Lyle, James, Ardeseo, Plaistow Wharf, Victoria Docks, E., Sugar Refiner.
1885. Lyle, Jno., 21, Mincing Lane, London, E.C., Sugar Refiner.
1902. Lyle, Robert F., Berry Yards Sugar Refinery, Greenock, N.B., Analytical Chemist.
1896. Lynn, Arthur H., 71, College Road, Bromley, Kent, Chemical Works Manager.
1906. Lynch, W. D., 10, Pinckney Street, Boston, Mass., U.S.A., Analytical Chemist.
1899. Lynn, R. Rankine, 7, Highburgh Terrace, Dowanhill, Glasgow, Chemical Engineer.
1902. Lyon, Edwd. H., 520, West 27th Street, New York City, U.S.A., Manufacturing Chemist.
O.M. Lyon, J. G., The Aire Tar Works, Knottingley, Yorks., Tar Distiller.
1906. Lyons, Robert H., Emporium, Pa., U.S.A., Chemist.
O.M. Lytle, A. M., North of Ireland Chemical Co., Ltd., 34, Victoria Street, Belfast, Ireland, Chemical Manufacturer.

M

1898. Maass, Frank, P.O. Box 1507, Paterson, N.J., U.S.A., Silk Dyer.
1904. Mabee, Fred. Carleton, Sumner Hall, Cambridge, Mass, U.S.A., Assistant in Chemistry.
1887. Mabery, Prof. Chas. F., Case School of Applied Science, Cleveland, Ohio, U.S.A., Professor of Chemistry.
1891. Macadam, Herbert E., Milton House, Selsdon Road, Wanstead, Essex, Manure Works Manager.
1894. Macadam, Stevenson, 55, York Place, Edinburgh, Analytical Chemist.
1891. Macallan, J., 3, Rutland Terrace, Clontarf, Dublin, Analytical Chemist.
1894. McAlley, Robt., Bankside, Falkirk, N.B., Paint Works Manager.
1892. Macara, Thos., jun., 30, Oakfield Road, Stroud Green, N., Chemist.
1889. McArthur, Jno., 196, Trinity Road, Wandsworth Common, S.W., Chemist.
1887. McArthur, J. B., Price's Patent Candle Co., Limited, Bromborough Pool, near Birkenhead, Chemist.
O.M. McArthur, J. S., 74, York Street, Glasgow, Consulting Chemist and Metallurgist.
1901. MacArthur, Jno. S., 15, St. John's Road, Pollokshields, Glasgow, Paint and Varnish Manufacturer.
1892. McArthur, Thos., 7, Temple, Dale Street, Liverpool, Drysalter and Dyewood Extractor.
1905. McCallum, A. L., Queen Building, Halifax, N.S., Canada, Analytical and Consulting Chemist.
1898. MacCallum, D. A., 389, Central Chambers, 93, Hope Street, Glasgow, Chemist.
O.M. McCallum, J. M., Southdene, Paisley, N.B., Soap Manufacturer.
1903. McCandless, Jno. M., State Laboratory, Atlanta, Ga., U.S.A., Analytical Chemist.
1894. McCann, Owen, c/o J. Gilton and Co., Oriel Street, Vauxhall Road, Liverpool, Printing Ink Manufacturer.

1905. McCaw, Major W. D., Library, Surgeon General's Office, Washington, D.C., U.S.A., Officer, Medical Department, U.S. Army.
1905. McCleary, Wm., 61, Station Road, Pendlebury, near Manchester, Finisher.
1903. McCourt, Cyril D., 7, Malwood Road, Balham Hill, S.W., Research Chemist (Morgan Crucible Co.).
O.M. McCowan, W., Essex Wharf, Narrow Street, Limehouse, E.
1897. McCrae, Dr. John, jun., P.O. Box 434, Pretoria, Transvaal, and (Journals) 7, Kirklee Gardens, Kelvinside, Glasgow, Chemist, Dept. of Agriculture.
1898. McCreath, Wm. D., c/o Quantock Vale Cider Works, North Petherton, Bridgewater, Cider Manufacturer.
1884. McCulloch, J., 13, Clarence Drive, Hyndland Road, Glasgow, Chemical Works Manager.
1900. McCulloch, John, Glencoe, Lostock Gralam, Cheshire, Chemical Engineer.
1903. McCully, R. E. J., Crown and Quarry Works, Frindsbury, Rochester, Kent, Analytical Chemist.
O.M. McDaniel, J. J., Woodlands, Bandon, Ireland, Distiller.
O.M. Macdonald, A., 72, Great Clyde Street, Glasgow.
1907. McDonald, Geo. G., 66, Madison Avenue, Toronto, Canada, Student.
1897. MacDonald, G. W., Beechfield, The Park, Birkenhead, Explosives Chemist.
O.M. Macdonald, J. W., Cleveland, The Glebe, Blackheath, S.E., Analytical Chemist.
1902. Macdonald, Peter, jun., c/o Mazapil Copper Co., Ltd., Concepcion del Oro (Apartado No. 5), Saltillo, Zacatecas, Mexico, Analytical Chemist.
1899. MacDonald, S. Fremont, c/o Ashtabula Hide and Leather Co., Ashtabula, Ohio, U.S.A., Tanner.
O.M. McDonald, T. McG., Walilabo Estate, St. Vincent, West Indies, and (Journals) 27, Prince of Wales Mansions, Battersea, S.W., Sugar Chemist.
1906. Macdougald, Geo. D., City Laboratory, 13, Shore Terrace, Dundee, Analyst.
1895. McDougall, Isaac, jun., 68, Port Street, Manchester, Student.
1890. McDougall, J. T., Dunolly, Morden Road, Blackheath, S.E., Manufacturing Chemist.
1906. McDowall, Wm., c/o Inglis, Lomax and Co., Antofagasta, Chile, South America, Analytical Chemist.
1906. McDowell, Alex. H., c/o General Chemical Co., Bayonne, N.J., U.S.A., Chemist.
1905. McDowell, Stewart H., 1239, South 47th Street, Philadelphia, Pa., U.S.A., Colour Maker.
1889. MacEwan, Peter, 64, Southwood Lane, Highgate, N., Editor of "Chemist and Druggist."
1891. McEwen, Atholl F., 40, Handen Road, Lee, S.E., Analytical Chemist and Assayer.
1901. McEwen, Duncan C., 175, St. Vincent Street, Glasgow, Metallurgical Chemist.
1902. McFarland, Alan R., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Works Manager.
O.M. Macfarlane, R. F., Tharsis Copper Works, East Moors, Cardiff, Works Manager.
1884. Macfarlane, Thos., 317, Queen Street, Ottawa, Canada, Analyst to Dominion of Canada.
1901. McFarlane, Walter, Sunnyside, Mansewood, Pollockshaws, Glasgow, Printworks Manager.
1890. McFarlane, W. W., 522, West 9th Street, Chester, Pa., U.S.A., Dyeworks Manager.
1893. McGhie, T. Burns, c/o Quirk, Barton and Co., Normandy Wharf, Rotherhithe, S.E., Analytical Chemist and Assayer.
1904. McGill, A., 317, Queen Street, Ottawa, Canada, Analytical Chemist.
1891. McGill, Dr. J. T., Vanderbilt University, Nashville, Tenn., U.S.A., Adjunct Professor of Chemistry.
1899. MacGillivray, Wm. A., c/o Swansea Safety Fuse Co., Pipe House Wharf, Swansea, Analytical Chemist.
1887. McGlashan, John, Cawnpore Sugar Works, Cawnpore, India, Technical Chemist.
1902. McGovney, Chas. S., Engineering Experiment Station, Urbana, Ill., U.S.A., Chemist.
1884. McGowan, John, Ash House, Talke, near Stoke-upon-Trent, Colliery Manager.
1906. McGregor, Russell, 20, Havelock Square, Sheffield, Analytical Chemist.
1905. McGrigor, G. D., Perranuthnoe, Marazion, Cornwall, Mine Owner.
1896. McIlhiney, Dr. Parker C., 145, East 23rd Street, New York City, U.S.A., Chemist.
1894. McIlwaine, Alf. W., Stoneferry, Hull, Oil Manufacturer.
O.M. MacIndoe, G. D., Ness Street, Invercargill, New Zealand, Public Analyst and Consulting Chemist.
1903. Macintire, Benj. Gould, P.O. Box 365, Rumford Falls, Maine, U.S.A., Chemist.
1904. Macintosh, J. C., Bruce Mines, Ont., Canada, Chemist.
1888. MacKean, Wm., 208, Bedford Hill, Balham, S.W., Technical Chemist.
O.M. McKechnie, D., Heath House, Runcorn, Copper Extractor.
O.M. McKechnie, D. M., Metal Works, Widnes, Lancashire, Copper Extractor.
1904. McKechnie, R. D., Productos Quimicos de Huelva, Sociedad Anonyma, Huelva, Spain, Chemist.
1887. McKellar, W. G., c/o United Alkali Co., Ltd., Eglinton Works, Irvine, N.B., Technical Chemist.
1906. Mackendrick, W. P., c/o Anglo-American Oil Co., Ltd., 13, St. Ann Street, Manchester.
1904. McKenna, A. G., 506, Hawkins Avenue, Braddock, Pa., U.S.A., Metallurgical Chemist.
1895. McKenna, Dr. Chas. F., 221, Pearl Street, New York City, U.S.A., Chemist.
1899. McKenzie, Alex. H., 17, North Street, North Adams, Mass., U.S.A., Colour Mixer.
1893. McKerrow, C. A., Thornbank, Knutsford Road, Alderley Edge, Cheshire, Consulting Chemist.
1905. McKerrow, W. J., c/o J. C. and J. Field, Ltd., Lambeth, S.E., Analytical Chemist.
1898. McKesson, John, 91, Fulton Street, New York City, U.S.A., Manufacturing Chemist.
1891. Mackey, W. McD., Victoria Chambers, Leeds, Analytical Chemist.
1900. McKillop, George F., Broxburn Oil Works, Broxburn, N.B., Works Chemist.
1890. McKillop, Jno., 93, Brook Green, London, W., Metallurgist.
1902. McKim, Wm., 37, Fairview Street, Yonkers, N.Y., U.S.A., Colour Maker.
1898. McLaurin, Robt., 414, Sauchiehall Street, Glasgow, Chemist.
1888. MacLean, Alex. S., 31, Bank Street, Greenock, N.B., Soap Refiner.
1905. McLellan, Basil G., c/o Rowntree & Co., Ltd., The Cocoa Works, York, Analytical Chemist.
1892. McLeod, Jas., Westhill, Cardross Road, Dumbarton, N.B., Analytical Chemist and Gas Examiner.
1903. MacMahon, F. W., 31, Marler Road, Forest Hill, S.E., Chemist (Oxychlorides, Ltd.).
1896. McMaster, Daniel, c/o Oxford Paper Co., Rumford Falls, Maine, Paper Mill Manager.
1894. Macmillan, Arch., Seaforth House, Blackhall, Midlothian.
1907. McMillen, Russell H., Research Department, Westinghouse Electric and Manufacturing Co., East Pittsburg, Pa., U.S.A., Chemist.
1903. McMullan, Charles, 4, William Street Chambers, Belfast, Ireland, Chemist.
1904. McMullen, Alan, 108, James Street, Dublin, Ireland, Brewer.
1889. McMurtrie, J. M., 320, Maxwell Road, Pollokshields, Glasgow, Brass Founder.
1900. McMurtrie, Dr. Wm. T., 480, Park Avenue, New York City, U.S.A., Chemist.
1895. McMurtry, G. C., Wallaroo Smelting Works, Wallaroo, South Australia; and (Subscriptions) c/o C. H. Izod, 84, Queen Victoria Street, London, E.C., Manager.
O.M. Macnab, W., 10, Cromwell Crescent, London, S.W., Analytical Chemist.

1907. McNaughton, Wm. G., c/o Canadian Rubber Co., Ltd., Papineau Square and Notre Dame, Montreal, Canada, Chemist.
1892. McVie, Jas. P., Ravenscraig, Canning Street, Hebburn on-Tyne, Analytical Chemist.
1894. McVitie, Robt., Biscuit Works, Willesden, N.W., Biscuit Manufacturer.
1901. Maertens, Emile, P.O. Box 1002, Providence, R.I., U.S.A., Engineer.
1895. Magnus, Isidor, 52, Leadenhall Street, London, E.C., Chemical Merchant.
1901. Magruder, Egbert W., Department of Agriculture, Richmond, Va., U.S.A., Chemist.
1906. Maguire, Peter, Hamer House, Rochdale, Lancashire, Chemist and Colourist.
1885. Mahon, R. W., N. Y. Central and Hudson River Railroad, West Albany, N.Y., U.S.A., Chemist.
1898. Main, Wm., Piermont, N.Y., U.S.A., Chemist.
1904. Mair, William, 7, Comiston Road, Edinburgh, Chemist.
1905. Major, Ernest, Eagle Paint Works, Snail's Bay, Balmain, Sydney, N.S.W., Australia, Paint Works Manager.
O.M. Major, J. Lewis, Welton Garth, Brough, East Yorks., Tar Distiller and Chemical Manufacturer.
1886. Mallinckrodt, Edw., Mallinckrodt Chemical Works, St. Louis, Mo., U.S.A., Manufacturing Chemist.
1897. Mallory, J. Halsey, Drawer 69, Columbia, S.C., U.S.A., Assistant Chemist (The American Cotton Oil Co.).
1896. Mann, E. A., Government Laboratory, Perth, Western Australia, Government Analyst.
1893. Mann, Harold H., Indian Tea Association, Royal Exchange Buildings, Calcutta, India, Research Chemist.
1899. Mann, Jas. S., 97, Greengate Street, Plaistow, Essex, Analyst.
1891. Mann, John C., 9, Lambert Street, Hull, Chemist.
1903. Mannhardt, Hans, c/o Heath & Milligan Manufacturing Co., 170, Randolph Street, Chicago, Ill., U.S.A., Chemical Engineer.
O.M. Mannington, H. T., Marchlea, Beaconsfield Road, Farnworth, Widnes.
1892. Mansbridge, Wm., 27, Elmbank Road, Sefton Park, Liverpool, Chemist.
1893. Marchlewski, Dr. L., Strzelecka 9, Krakow, Austria.
1904. Marckworth, O. S., Ohio Testing Laboratory, 25 and 26, Board of Trade, Columbus, Ohio, U.S.A., Analytical Chemist.
1903. Mardick, Jno. R., Westminster, Md., U.S.A., Chemical Engineer.
1904. Maréchal, H., Eugene Maréchal et fils, Vénissier (Rhone), France, Oilcloth Manufacturer.
1883. Markel, Dr. K., Tower House, Bewsey, Warrington, Technical Chemist.
1905. Marland, Percy, c/o Brotherton and Co., Ltd., Ammonia Works, Wakefield, Yorks., Chemist.
1905. Marlatt, Wilbur T., Oakville, Ont., Canada, Leather Manufacturer.
1902. Marriott, F. Grant, 14, Selby Street, Toronto, Canada, Chemical Student.
1904. Marris, H. C., The Russian Steam Oil Mills Co., 32, Kourlandski Street, St. Petersburg, Russia, Analytical Chemist.
1904. Marschall, Adolf J., Madison, Wis., U.S.A., Chemist.
1901. Marsden, Dr. Fred., c/o Messrs. H. Ashwell & Co., New Basford, Nottingham, Chemist.
1906. Marsden, Oliver, Manor Road Mill, Victoria Road, Leeds, Cashier.
1905. Marsh, John, Massarah Cement Works, near Heluan, Egypt, Cement Works Chemist.
O.M. Marsh, J. T., Ammonia Soda Works, Fleetwood, Lancashire, Chemist.
1883. Marsh, W., Union Alkali Co., Soho Works, Ancoats, Manchester, Chemical Manufacturer.
1895. Marshall, Arthur, The Cottage, Dartford, Kent, Explosives Chemist.
1906. Marshall, Dexter, c/o McClure Co., Fourth Avenue, and 23rd Street, New York City, U.S.A.
1895. Marshall, Francis G., 4, Woodhouse Terrace, Bewick Road, Gateshead, Technical Chemist.
1891. Marshall, Dr. Hugh, 12, Lonsdale Terrace, Edinburgh, Professor of Chemistry.
1901. Marshall, Jos. W., 143, De la Pole Avenue, Hull, Science Lecturer.
1896. Marshall, Percy S., Union Laboratory, Half Moon Street, Huddersfield, Assistant Chemist.
1883. Marshall, Wm., Carisbrook, Queen's Road, Cheadle Hulme, Cheshire, Dyer.
1884. Marshall, Wm., Barkley, Teddington, Middlesex, Analytical Chemist.
1904. Marston, John P., 247, Atlantic Avenue, Boston, Mass, U.S.A., Merchant.
1894. Martin, Alex. M., Hillview, Twechar by Glasgow, Analytical Chemist
1895. Martin, Chas., H., 40, Bolton Road, Pendleton, Salford, Oil and Soap Works Manager.
O.M. Martin, N. H., Ravenswood, Low Fell, Gateshead-on-Tyne, Manufacturing Chemist.
1899. Martin, Wm. E., c/o Kynoch Ltd., Arklow, Co. Wicklow, Ireland, Chemist.
O.M. Martin, W. H., 183B, King's Road, Chelsea, London, S.W., Analytical Chemist.
1887. Martineau, Sydney, Northwood, Rydal Road, Streatham, S.W., Sugar Chemist.
1894. Martyn, T. Graham, 11, Stratton Terrace, Truro, Cornwall, Metallurgist.
1905. Marx, Dr. Emil, Fährstrasse 102, Wilhelmsburg, Hamburg, Germany, Research Chemist.
1902. Marx, Joseph S., California Powder Works, Pinole, Cal., U.S.A., Chemist.
1905. Marx, Dr. Max, 81, Shanley Avenue, Newark, N.J., U.S.A., Manufacturing Chemist.
1904. Mason, Dr. Edward D., 22, George Road, Edgbaston, Birmingham, Scientific Apparatus Dealer.
1906. Mason, Frederic S., 90, Beckman Street, New York City, U.S.A., Manufacturing Chemist.
1904. Mason, Glen F., c/o H. J. Heinz Co., Pittsburg, Pa., U.S.A., Chemist.
1887. Mason, J. Francis, Eynsham Hall, Witney, Oxon.
1906. Mason, M. Edgar, 510, Talbot Avenue, Boston, Mass., U.S.A., Chemist.
1892. Mason, Thos., Beech Avenue, Nottingham, Manufacturing Chemist.
1906. Massa, Corradino, Castelguelto Parmense, Parma, Italy, Sulphuric Acid and Fertiliser Manufacturer.
O.M. Masson, Prof. D. Orme, University of Melbourne, Victoria, Australia, Professor of Chemistry.
1904. Masson, Victor E., Pleasant Valley Wine Co., Rheims, Steuben Co., N.Y., U.S.A., Chemist.
1902. Masujima, Prof. Bunjiro, 23, Midoricho Itchome, Honjoku, Tokyo, Japan, Prof. of Applied Chemistry.
1903. Masure, Gaston, 7, Rue de Constantine, Rouen, France, Chemist.
1902. Masury, Fred L. M., Lock Box 144, Sharon, Pa., U.S.A., Explosives Manufacturer.
O.M. Mather, J., Blaydon Chemical Works, Blaydon-on-Tyne, Manager.
1904. Mather, J. Cecil, 15, The Holloway, Runcorn, Cheshire, Works Chemist.
1900. Mather, Wm., c/o British Aluminium Co., Ltd., Larne Harbour, Co. Antrim, Ireland, Chemist.
1907. Matheson, A. Greville E., c/o South Staffordshire Mond Gas Co., Tipton, South Staffordshire, Engineer.
1890. Matheson, W. J., c/o Cassella Colour Co., 182, Front Street, New York City, U.S.A., Chemical Merchant.
1901. Mathew, W. E. B. de Vere, Shanklin, Lucion Road, Upper Tooting, S.W., Analytical Chemist.
1900. Mathews, Dr. Jno. A., c/o Crucible Steel Co. of America, Syracuse, N.Y., U.S.A., Chemist.
1898. Mathewson, E. P., Anaconda, Mont., U.S.A., Metallurgist.
1888. Mâtos, Louis J., 105, North 19th Street, East Orange, N.J., U.S.A., Chemist.
1896. Matsui, G., c/o Japan Sugar Refinery Co., Onagigawa, Tokio Japan, Chemical Engineer.
O.M. Matthews, Chas. G., 31, Stapenhill Road, Burton-on-Trent, Brewing Chemist.

1899. Matthews, Dr. J. Merritt, 320, South Broad Street, Philadelphia, Pa., U.S.A., Professor of Chemistry and Dyeing (Philadelphia Textile School).
1889. Mawdsley, W. H., c/o Gold Mining Co., Ltd., Mount Morgan, Queensland, Chemist.
1906. Mawson, Fred. E., 135, Pearl Street, Boston, Mass., U.S.A., Dyestuff Merchant.
1903. Maxim, Hudson, 698, St. Mark's Avenue, Brooklyn, N.Y., U.S.A., Chemist and Mechanical Engineer.
1894. Maxwell, Jno., Solway Chemical Works, Silloth, and (communications) English Street, Carlisle, Cumberland, Chemical Manure Manufacturer.
1903. Maxwell, Orin P., Piedmont, Mineral Co., West Va., U.S.A., Chemist.
1897. May, George H., c/o Fabrikoid Co., Newburgh, N.Y., U.S.A., Assistant Chemist.
1884. Mayenfeld, Dr. E. von Salis. *See* Salis-Mayenfeld, Dr. E. von.
1903. Mayer, Andrew, jun., 129, York Street, Brooklyn, N.Y., U.S.A., Chemist.
1896. Mayfield, A. S., Thirlmere, Newland, Hull, Analyst.
1892. Mayfield, H. B., Normanhurst, Mundy Street, Heanor, near Nottingham, Dyer.
1885. Mayhew, E. W. A., High Street, Freemantle, Western Australia, Manufacturing Chemist.
1900. Maywald, F. J., 1028, 72nd Street, Brooklyn, N.Y., U.S.A., Technical Chemist.
1902. Meade, Richd. K., Nazareth, Pa , U.S.A., Chemist.
1904. Meads, Charles J., Bel Air, Dartmouth, Inland Revenue Officer.
1898. Meeds, Alonzo D., 2424, Harriet Avenue, Minneapolis, Minn., U.S.A., Analytical Chemist.
1896. Meggitt, Loxley, Wheatsheaf Works, Alexandria, Sydney, N.S.W., Australia, Analytical Chemist.
1901. Meier, Dr. Franz, Basle Chemical Works, Basle, Switzerland, Chemist.
1888. Meikle, Jno., 8, Melrose Street, Great Western Road, Glasgow, Journalist.
1902. Melcher, Arthur C., 58, Bowen Street, Newton Centre, Mass., U.S.A., Chemist.
O.M. Meldola, Prof. R., F.R.S., 6, Brunswick Square, London, W.C., Professor of Chemistry.
1901. Meldrum, Dr. And. N., 16, Mooroaks Road, Sheffield, Lecturer on Chemistry.
O.M. Mellon, W. W., 9, Glenart Avenue, Blackrock, Co. Dublin, Ireland, Manufacturing Chemist.
O.M. Mellor, S., Magnesium Metal Co., Patricroft, Manchester, Metal Refiner.
1884. Melville, D., 2, Melville Avenue, Delray, Detroit, Mich., U.S.A., Chemical Works Manager.
1893. Mensching, Dr. C., Anilinfabrik., Greppen bei Bitterfeld, Germany, Chemist.
1905. Menzies, David, 11, Camphill Avenue, Langside, Glasgow, Analyst.
O.M. Menzies, R. C., Inveresk Mills, Musselburgh, N.B., Paper Maker.
1892. Mercer, C. A., 34, Camomile Street, London, E.C., Chemical Apparatus Maker.
1886. Mercer, J. B., 4, Tabley Road, Knutsford, Cheshire.
1890. Merck, E., Darmstadt, Germany, Manufacturing Chemist.
1905. Merck, George, Merck and Co., University Place, New York City, U.S.A., Manufacturing Chemist.
1887. Merrell, Geo., Lock Box 780, Cincinnati, Ohio, U.S.A., Manufacturing Chemist.
1899. Merrill, Frank H., 2420, Ocean View Avenue, Los Angeles, Cal., U.S.A., Factory Superintendent.
1903. Merrill, Herbert C., c/o Eimer & Amend, 205, Third Avenue, New York City, U.S.A., Chemical Engineer.
1906. Merrils, Fred. J., 25, Figtree Lane, Sheffield, Analytical Chemist.
1905. Merrin, A. C., 44, Bishopsgate Street Without, London, E.C., Assistant Editor and Analyst.
1902. Merritt, Wm. G., 643, Second Avenue, Detroit, Mich., U.S.A., Chemical Engineer (Berry Bros. Varnish Manufacturers).
1904. Merry, Jno. B., 12, Mayfield Road, Handsworth, Birmingham, Metallurgical Chemist.
1903. Mersan, Ferdinand de, Fairfield, Chestnut Avenue, Boston Spa, Yorks, Chemist.
1903. Merseau, Gail, 181, Pearl Street, New York City U.S.A., Chemist.
1905. Merz, Eugene, P.O. Box 216, Newark, N.J., U.S.A. General Superintendent, Heller and Merz Co.
1905. Merzbacher, Aaron, Laboratory, Reading Iron Co. Reading, Pa., U.S.A., Chemist.
1897. Meslans, Prof. M., 59 Quai de la Baronnie, Ablon (Seine et Oise), France, Professor of Chemistry.
O.M. Messel, Dr. R., 147, Victoria Street, London, S.W. Chemical Manufacturer.
1899. Metcalf, Howard F., Farr Alpaca Co., Holyoke Mass., U.S.A.
1886. Metcalf, Jno., Moorfield, Altham, near Accrington Tar Distiller.
1905. Methley, Bernard, 21, Clifton Mount, Rotherham, Yorks., Engineering Chemist.
1898. Metz, Herman A., P.O. Box 78, New York City, U.S.A., Chemical Merchant.
1905. Metzis, Josef, Anglicia Petroleum Co., Drohobycz., Galicia, Austria, Manager of Refinery.
1900. Mewborne, Robt. G., c/o Kentucky Tobacco Product Co., Louisville, Ky., U.S.A., Chemist.
1904. Meyenberg, Dr. Alex., 9, Nelson Street, Plymouth Grove, Manchester, Works Manager.
1907. Meyer, Dr. Erwin, The Hartford Rubber Works Co., Hartford, Conn., U.S.A.
1898. Meyer, Dr. Franz, 52, Broadway, New York City, U.S.A., Metallurgical and Chemical Engineer.
1902. Meyer, Dr. Fredk. L., 2028, Park Avenue, Philadelphia, Pa., U.S.A., Chemist.
1900. Meyer, Karl, Sortedams Dossering 95A, Copenhagen, O., Denmark, Technical Chemist.
1904. Meyer, Prof. Dr. Richard, Technische Hochschule Braunschweig, Germany, Professor of Chemistry
1902. Meyrick, L. J., 137, City Road, Birmingham Assistant Analyst.
1904. Mighill, Thos. A., 15, Exchange Street, Boston Mass., U.S.A., Chemist.
1906. Mihalovitch, Sydney F., 514, East Pearl Street Cincinnati, Ohio, U.S.A., Chemist.
1896. Miles, G. Wellington, 29, Central Street, Boston Mass., U.S.A., Analytical Chemist
1889. Milestone, W. C., 7, Heathfield Road, Wandsworth Common, S.W., Chemical Works Manager.
1899. Millar, Jas. H., P.O. Box 120, Durban, Natal, Manufacturing and Analytical Chemist.
1897. Millard, Edgar J., 40–42, Charlotte Street, London, E.C., Chemist and Manager.
1903. Millen, J. Dunlop, Mount Bischoff Mine, Waratah, Tasmania, Assistant General Manager.
1883. Miller, Dr. A. K., Kilvert's Buildings, Withy Grove, Manchester, Analytical Chemist.
1904. Miller, Chas. E., 58, Chardon Street, Boston, Mass., U.S.A., Manufacturing Chemist.
O.M. Miller, E. V., Sugar Works, Chelsea, Auckland, New Zealand, Sugar Works Chemist.
1899. Miller, Geo., Clydesdale, Groes Road, Cressington, Liverpool, Technical Chemist.
1900 Miller, Hampton K., Lake City, Flo., U.S.A., Chemist (Florida A. and M. College).
1893. Miller, Dr. Harry E., 1015, Chestnut Street, Oakland, Cal., U.S.A., Chemist.
1902. Miller, H. Harold, 303, Front Street East, Toronto, Canada, Chemist.
1883. Miller, Dr. H. von, Beatrixgasse 32, Wien, Austria, Chemical Manufacturer.
1904. Miller, Jas., Pharmacist.
1894. Miller, Dr. John A., 40–45, Lewis Block, Buffalo, N.Y., U.S.A., Consulting Chemist, State Analyst.
1894. Miller, J. Carlile, 188, St. Vincent Street, Glasgow, Manufacturing Chemist.
1888. Miller, J. Hopkins, 5, Catherine Street, Parliamentary Road, Glasgow, Dyeworks Chemist.
1889. Miller, Jno. Poynter, Sandilands Chemical Works, Aberdeen, Technical Chemist.
1899. Miller, P. Schuyler, 3500, Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemist.
1901. Miller, Stuart B., c/o Eastern Dynamite Co., Lewisburg, Ala., U.S.A., Chemical Engineer.

1904. Miller, William Exley, c/o The Arizona Copper Co., Ltd., 29, St. Andrew Square, Edinburgh, Secretary.
1901. Miller, W. Lash, 50, St. Alban Street, Toronto, Canada, Associate Professor of Physical Chemistry.
1884. Miller, W. M., Caledonia Estate, Prov. Wellesley, Penang, S.S., Sugar Chemist.
1902. Milligan, R. E., New York Continental Jewell Filtration Co., 15, Broad Street, New York City, U.S.A., Chemical Engineer.
1904. Millroy, Alfred T., 53, Guilford Street, London, W.C., Laboratory Furnisher.
O.M. Mills, Prof. E. J., F.R.S., 64, Twyford Avenue, West Acton, W., Emeritus, Professor of Technical Chemistry and Consulting Chemist.
1904. Mills, Dr. J. E., University of North Carolina, Chapel Hill, N.C., U.S.A., Associate Professor of Chemistry.
1905. Mills, Wm. Henry, 45, Wall Street, New York City, U.S.A., Merchant.
1906. Mills, Wm. Hobson, Northern Polytechnic Institute, Holloway, London, N., Lecturer in Chemistry.
1905. Milne, Thomas, c/o The Gas Light and Coke Co., Ltd., 4, Fenchurch Avenue, London, E.C., Chemical Products Salesman.
1903. Milnes, Cresswell, Arlesey, near Hitchin, Herts., Cement Works Manager.
1887. Milnes, Edmund, Seedfield, Bury, Lancashire, Dyeing Extract Maker.
1902. Milnes, Ernest E., c/o Joseph Smithson, Ltd., India Buildings, Halifax, Yorks., Chemist.
1901. Milroy, Andrew, Glenbarry, Giffnock, Glasgow, Manager.
1895. Miner, Harlan S., c/o Welsbach Light Co., Gloucester City, N.J., U.S.A., Technical Chemist.
1889. Miniati, T. K., Penketh, near Warrington, Chemist.
1904. Minor, John C., jun., Saratoga Springs, N.Y., U.S.A., Manufacturer.
1895. Mitchell, Chas. A., c/o Beaufoy and Co., South Lambeth Road, S.W., Analyst.
1901. Mitchell, Frank H., c/o Dill and Collins, Richmond and Tioga Streets, Philadelphia, Pa., U.S.A., Tutor in Chemistry.
1898. Mitchell, G. D. H., c/o S. S. White Dental Manufacturing Co., Prince's Bay, Staten Island, N.Y., U.S.A., Chemist.
1883. Mitchell, J. W., Plantation House, Clough Fold, near Manchester, Waste Bleacher.
1906. Mitchell, Oswald H., c/o Basil Turner, Woolwich, Sydney, N.S.W., Australia, Assayer.
1904. Mitsugi, R., Weimarerstrasse 9, II., Charlottenburg, Germany, Chemist.
O.M. Mitting, E. Kennard, 38, Harold Road, Norwood, S.E., Technical Chemist.
1902. Möckel, Heinrich A., Paper Mill, Altdamm, near Stettin, Germany, Chemist and Engineer.
1905. Modi, Dr. E. M., Opposite Grant Road Station, Sleater Road, Bombay, India, Manufacturing and Analytical Chemist.
1906. Moe, Eldor H., 24, South First West Street, Salt Lake City, Utah, U.S.A., Chemist.
1903. Möhlau, Prof. Dr. Rd., Semperstrasse 4, Dresden, A., Germany, Professor of Colour Chemistry.
O.M. Mohr, Dr. B., 69a, Parliament Hill, Hampstead, N.W., Consulting Chemist and Metallurgist.
1894. Mole, Herbert B., The Croft, Shepton Mallet, Somerset, Brewer.
1902. Molesworth, F. H., Jersey Road, Antarmon, N.S.W., Australia, Analytical Chemist.
1906. Moller, Emil A., 44, Sherman Avenue, Tompkinsville, N.Y., U.S.A., Manager (Sanitas Co.).
1903. Mommers, Richard, South Manchester, Conn., U.S.A., Chemical Engineer.
1899. Mond, Emile S., 22, Hyde Park Square, London, W., Technical Chemist.
O.M. Mond, Dr. L., F.R.S., 20, Avenue Road, Regent's Park, N.W.; and 64, Via Sistina, Rome, Alkali Manufacturer.
1891. Mond, Robt. L., Winnington Hall, Northwich, Chemist.
1905. Monell, Ambrose, 43, Exchange Place, New York City, U.S.A., President (International Nickel Co.).
1906. Monier-Williams, G. W., The Lamman, Esher, Surrey.
1890. Moodie, Wm. E., Alexandria Works, Alexandria, N.B., Analytical Chemist.
1901. Moody, Chas. J., Lake View Consols Mine, Boulder, West Australia, Analyst and Assayer.
1905. Moody, Dr. Gerald T., Lorne House, North Dulwich, S.E., Lecturer on Chemistry.
1898. Moody, Dr. Herbert R., College of the City of New York, New York City, U.S.A., Science Instructor.
1884. Mook, Chas., 2, Kapellenstrasse, Eisenach, Germany, Alkali Works Director.
1903. Mooney, F. M., 118, Pembroke Road, Dublin, Chemical Manure Manufacturer.
1903. Mooney, Geo. A., 310, St. Paul Street, Montreal, Canada, Chemical Merchant.
1902. Mooney, Luke, 36, West 52nd Street, Bayonne, N.J., U.S.A.
1887. Moore, Chas. C., 33, Clarendon Road, Garston, Liverpool, Chemist.
1901. Moore, Chas. W., 38, Demesne Road, Whalley Range, Manchester, Chemist.
1902. Moore, Fred., Victoria Chemical Co., Ltd., Victoria, B.C., Canada, Manufacturing Chemist.
1906. Moore, F. H., 39, Lime Street, London, E.C., Analytical Chemist.
1892. Moore, Dr. Geo. D., 201, Salisbury Street, Worcester, Mass., U.S.A., Professor of Chemistry.
1905. Moore, Leslie R., 173, Oakleigh Road, Newton, Mass., U.S.A., Chemist.
1899. Moore, Quintin, jun., c/o Wm. Beardmore & Co., Ltd., Parkhead Forge, Glasgow, Works Manager.
1885. Moore, R. T., 142, St. Vincent Street, Glasgow, Mining Engineer.
1899. Moore, Dr. Russell W., 47, Linden Place, Orange, N.J., U.S.A., Chemist (U.S. Appraiser's Office).
1890. Moore, Thos., Laboratoire du Service Local, Noumea, New Caledonia, Analytical Chemist.
1905. Moorwood, F. Colin, c/o Flockton, Tompkin and Co., Ltd., Newhall Steelworks, Sheffield, Steel Manufacturer.
1903. Moran, Geo. A., 333, Haverhill Street, Lawrence, Mass., U.S.A., Chemist.
1890. Mordle, F. Dare, Guilderoy, Matlock Bath, Derbyshire, Starch Manufacturer.
1902. More, Andrew, 61, Quarrendon Street, Fulham, S.W., Government Analyst.
1906. Morewood, C. Darcy, Frodingham Ironstone Mines, Scunthorpe, near Doncaster, Analytical Chemist.
1901. Morgan, Dr. Gilbert T., Royal College of Science, South Kensington, S.W., Demonstrator of Chemistry.
1905. Morgan, Jerome J., College Park, Md., U.S.A., Teacher.
1890. Morgan, J. Jas., Laboratory, Cammell, Laird and Co., Workington, Cumberland, Assayer.
1907. Morgan, Leonard G., United States Mint, Philadelphia, Pa., U.S.A., Electro-Chemist.
1906. Morgan, Thos., "Meirion," Dovedale Road, Wavertree, Liverpool, Manufacturing Chemist.
1885. Morgans, Thos., 60, Queen Square, Bristol, Civil Engineer.
1907. Morhous, Oakley A., 1839, 82nd Street, Brooklyn, N.Y., U.S.A., Chemist.
1902. Morison, Jas., Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Analytical Chemist.
1897. Morison, Samuel L., c/o John Brett, 8, Lendal, York, Water Engineer.
O.M. Moritz, Dr. E. R., 45, Great Tower Street, London, E.C., Brewing Chemist.
1885. Morley, Dr. H. Forster, 5, Lyndhurst Road, Hampstead, N.W., Professor of Chemistry.
1902. Morrell, Dr. R. S., Messrs. Mander Bros., Colour and Varnish Works, Wolverhampton, Chemist.
1884. Morrice, Jas. A., 1, Prince's Terrace, Dowanhill, Glasgow, Starch and Gum Manufacturer.
1906. Morris, A. H., 27, Hartington Road, Bolton, Lancs., Brewer.

1898. Morris, Edgar F., c/o Cornbrook Chemical Co., Ltd., Colour Works, Stockport, Research Chemist.
1897. Morris, Harry, The Hall, Hexthorpe, Doncaster, Chemical Merchant.
1890. Morris, Herbert N., 13, Birch Grove, Rusholme, Manchester, Technical Chemist.
O.M. Morris, J. Haydn, 22, Largo das Fontanhas, Lisbon, Portugal, Technical Chemist.
1902. Morrison, Jos., Wellfield, Farnworth, Widnes, Manager.
1906. Morrow, Jas. M., 7, Rosebery Terrace, Kirkcaldy, N.B., Analytical Chemist.
1901. Morse, Willard S., Seaford, Del., U.S.A., Assistant Manager.
O.M. Morson, T., 38, Elsworthy Road, Primrose Hill, N.W.; and (Journals) Summerfield Works, Ponder's End, N., Manufacturing Chemist.
1904. Morson, Thos. D., 14, Elm Street, Gray's Inn Road, London, W.C., Chemist.
1906. Morson, T. Pierre, 14, Elm Street, Gray's Inn Road, London, W.C., Chemical Manufacturer.
1889. Morton, Jas., Dalquhurn Works, Renton, N.B., Dyeworks Manager.
1897. Morton, Jno., North Road, St. Helens, Lancashire, Analytical Chemist.
1902. Mosbaugh, F. R., c/o Heald Extract Co., Lynchburg, Va., U.S.A., Chemist.
1905. Moseley, F. A. D. H., Box 1057, Johannesburg, Transvaal, Analytical Chemist.
1888. Mosenthal, Henry de, 220, Winchester House, Old Broad Street, E.C., Explosives Company Manager.
1903. Mosher, Walter R., 4274, West Avenue, Buffalo, N.Y., U.S.A., Chemist.
1906. Moss, Wm., Moss Chemical Manufacturing Co., Foot of Carlaw Avenue, Toronto, Canada, Chemical Manufacturer.
1894. Moszczenski, J. von, Tartar Chemical Co., Ninth Street and Gowanus Canal, Brooklyn, N.Y., U.S.A., Consulting Chemist.
1897. Motion, Jno., c/o Valvoline Oil Co., Edgewater, N.J., U.S.A., Oil Refinery Chemist.
1887. Moul, Frank, Aldersgate Chemical Works, Southall, Technical Chemist.
1901. Moule, Jno. W., c/o The Chillagoe Co., Ltd., Chillagoe, Queensland, Metallurgist.
1884. Moult, J., Underhill, Low Fell, Gateshead-on-Tyne, Secretary.
1898. Moulton, Prof. Chas. W., Vassar College, Poughkeepsie, N.Y., U.S.A., Professor of Chemistry.
1905. Moulton, Rt. Hon. Sir J. Fletcher, F.R.S., 57, Onslow Square, London, S.W., Lord Justice of Appeal.
1892. Mount, Edw., Oaklands, Aughton, near Ormskirk, Assistant Secretary (United Alkali Company).
1905. Mrazsek, F. M., 29, Mincing Lane, London, E.C., Consulting Chemist.
1904. Muckenfuss, A. M., c/o University of Mississippi, University, Miss., U.S.A., State Chemist.
1907. Mueller, Dr. Carl, The Heyden Chemical Works, Garfield, N.J., U.S.A., Chemist.
1890. Muir, Jas. Stanley, 8, Westminster Gardens, Glasgow, W., Chemist.
1906. Muir, Wm., Regent Factory, Linlithgow, Scotland, Analytical Chemist.
1894. Muir-Smith, W., c/o A. B. Fleming and Co., Ltd., Caroline Park, Edinburgh, Oil Works Manager.
O.M. Müller, Dr. H., F.R.S., 13, Park Square East, Regent's Park, London, N.W., Research Chemist.
1896. Mundy, Lionel, 27, Merton Road, Kensington, W., Importer of Unfermented Wines.
1887. Munroe, Prof. Chas. E., George Washington University, Washington, D.C., U.S.A., Professor of Chemistry and Dean.
1900. Munsell, Dr. Chas. E., c/o Devor and Raynolds Co., 110, Horatio Street, New York City, U.S.A., Colour Chemist.
1900. Munton, Fred T., The Oak House, Winsford, Cheshire, A.R.S.M., Analytical Chemist.
1897. Murch, D. Wilshin, 6, Victoria Road, Wednesbury, Staffs., Chemist.
1904. Murdoch, Alexander, 557, Alexandra Parade, Dennistoun, Glasgow, Analytical Chemist.
1886. Murdoch, R. H. M., Shore Road, Stevenston, Ayrshire, Explosives Chemist.
1899. Murphy, Albert J., The Laboratory, 11, Lyddon Terrace, Leeds, Brewer's Chemist.
1906. Murphy, Frederic W., Standard Sugar Refinery, Granite Street, South Boston, Mass., U.S.A., Chemist.
1901. Murray, Benjamin L., c/o Merck and Co., University Place, New York City, U.S.A., Chemist.
1903. Murray, Chas. B., 611, Bailey Farrell Building, Pittsburg, Pa., U.S.A., Chemist.
1899. Murray, Jas. J., Iron King Mine, Blanchard, Arizona, U.S.A., Mining Engineer.
1901. Murray, Jas. P., Toronto Carpet Manufacturing Co., Ltd., King Street and Fraser Avenue, Toronto, Canada, Carpet Manufacturer.
1898. Murray, Rd., c/o Brotherton and Co., Ltd., Ammonia Works, Holmes Street, Leeds, Analyst.
1896. Murray, Dr. Thos. S., 1, Nelson Street, Dundee, Professor of Chemistry.
1905. Murray, Wm. Wallace, c/o Union Abattoir Co., Baltimore, Md., U.S.A., Chemist.
1905. Murrill, Dr. Paul I., P.O. Box 986, Wilmington, Del., U.S.A., Representative, E.I. du Pont Co.
O.M. Muspratt, E. K., Seaforth Hall, near Liverpool, Alkali Manufacturer.
1894. Muspratt, Max, 2, Mannering Road, Sefton Park, Liverpool, Technical Chemist.
O.M. Muspratt, S. K., 14, Northgate, Regent's Park, N.W., Alkali Manufacturer.
1907. Musso, Louis A., Department of Agriculture, 140, George Street, North Sydney, N.S.W., Australia, Assistant Viticulturist.
O.M. Muter, Dr. Jno., Winchester House, Horley, Surrey; and (Journals) 325, Kennington Road, London, S.E., Chemical Lecturer.
1895. Muurling, I. J. R., P.O. Box 1935, New York City, U.S.A., Dyestuff Importer.
1891. Myers, Wm. S., Nitrate of Soda Propaganda, 12, John Street, New York City, U.S.A., Director.
1906. Myles, C. D., 16, St. Loo Mansions, Cheyne Gardens, London, S.W.

N

1902. Naef, Dr. Ernest E., Clydach, Swansea, South Wales, Chemist.
1903. Nagel, Dr. Oscar, c/o De la Vergne Machine Co., Foot of East 138th Street, New York City, U.S.A., Chemist.
1903. Nagel, Oskar H. L., c/o Larned and Baker Co., Syracuse, N.Y., U.S.A., Superintendent (Chemical Works).
1897. Nairn, Michael, Ben Dhu, Kirkcaldy, N.B., Linoleum Manufacturer.
1901. Nakagawa, Sosuke, c/o Tokyo Ryusan Kwaisha, Kameido Oshimacho, near Tokyo, Japan, Chief Engineer.
1903. Nakayama, Takakichi, c/o Fuji Paper Co., Sanjikkenbori, Tokyo, Japan, Chemist.
1901. Nanabhai, Krishnalal, 8-10, Nepean Sea Road, Malabar Hill, Bombay, India, Technological Chemist.
1893. Napier, Jno. W., Gas Works, Alloa, N.B., Manager and Chemist.
1904. Napper, Sidney S., c/o S. Courtauld & Co., Ltd., Foleshill Road, Coventry, Chemist.
1903. Nash, A. Douglas, 280, State Street, Flushing, N.Y., U.S.A., Glass Manufacturer.
1897. Nash, Leonard M., Westlands, Princess Road, Finsbury Park, N., Works Chemist.
1905. Nash, W. A., Corn Exchange Bank, New York City, U.S.A., President, Corn Exchange Bank.
1906. Nathan, Albert, 60, Wall Street, New York City, U.S.A., Patent Lawyer.

1900. Nathan, Lt.-Col. Sir Frederic L., R.A., Royal Gunpowder Factory, Waltham Abbey, Essex, Superintendent.
1892. Naylor, Wm., 3, Garstang Road, Fulwood, Preston, Lancs., Chemist.
O.M. Naylor, W. A. H., 38, Southwark Street, London, S.E., Manufacturing Chemist.
1899. Neate, Percy J., "Belsize," Watts Avenue, Rochester, Kent, Director of Cement Co.
1902. Neave, Geo. B., Technical College, Montrose Street, Glasgow, Assistant to Professor of Chemistry.
1905. Neech, Herbert R., St. Catherine's, Lincoln, Chemical Engineer.
1905. Needham, Edward R, 48, Paton Street, Glasgow, Manufacturing Chemist.
1905. Neff, Robert W., 22, India Square, Boston, Mass., U.S.A., Chemical Manufacturer.
1906. Neil, Dr. Archibald A., 82, Eccles Old Road, Manchester, Chemical Engineer.
1898. Neil, Jas. Millar, 12 Woodland Avenue, Toronto, Canada, Technical Chemist.
1890. Neill, Geo. D., Drumslea, Greenock, N.B., Sugar Refiner.
1898. Neilson, Alex. McG., P.O. Box 615, Durban, Natal, Analytical Chemist.
1889. Neilson, Thos., Highland Boy Smelter, Murray, Utah, U.S.A., Metallurgical Chemist.
1903. Neiman, Howard S., 122, Hudson Street, New York City, U.S.A., Manufacturing Chemist.
1902. Neish, Arthur C., Columbia University, New York City, U.S.A., Chemist.
1897. Nelson, Walter, Emscote Mills, Warwick, Gelatin Manufacturer.
1906. Nestell, Raymond J., 115, West 68th Street, New York City, U.S.A., Chemical Instructor.
1901. Neufville, Dr. Rudolf de, c/o Metallurgische Gesellschaft, Frankfort a/M., Germany.
1902. Neumann, Dr. Edgar, 7 and 8, Idol Lane, London, E.C.
1903. Neumann, Dr. Max, Capellenstrasse 51, Wiesbaden, Germany.
O.M. Newall, F. S., Washington Station R.S.O., Co. Durham, Chemical Manufacturer.
1905. Newall, Joseph, 28, Greenway Road, Runcorn, Cheshire, Chemist.
1889. Newberry, Spencer B., Sandusky Portland Cement Co., Sandusky, Ohio, U.S.A., Manager.
1906. Newkirk, Chas. C., c/o The M. Werk Co., 411, Poplar Street, Cincinati, Ohio, U.S.A., Chemist.
O.M. Newlands, B. E. R., 2, St. Dunstan's Hill, London, E.C., Analytical and Consulting Chemist.
O.M. Newlands, W. P. R., 10, Cricklade Avenue, Streatham Hill, S.W., Sugar Chemist.
O.M. Newton, Jno., Manor Works, Rotherhithe New Road, London, S.E., Manure Manufacturer.
1900. Newton, Dr. Wm., Ashcombe, London Road, Dorking, Chemist.
1901. Nibelius, Axel W. T., American Forcite Powder Manufacturing Co., Landing, N.J., U.S.A., Chemist.
1904. Nichols, C. W., 406, Clinton Avenue, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
1905. Nichols, E. Remington, 25, Broad Street, New York City, U.S.A., Treasurer (Nichols Chemical Co.).
1884. Nichols, J. A., Stanley Mount, New Mills, near Stockport, Teacher of Science.
1888. Nichols, Wm. H., 25, Broad Street, New York City, U.S.A., Chemical Manufacturer.
1905. Nichols, W. H., jun., 25, Broad Street, New York City, U.S.A., President, San Carlos Copper Co.
1897. Nicholson, Harry, St. David's Mines, Ltd., Bontddu, Dolgelly, North Wales, Assayer.
1904. Nicholson, Wilfred E., Hunslet Chemical Works, Leeds, Chemical Manufacturer.
1897. Nicholson, Wm. J., Ardeer, Stevenston, Ayrshire, N.B., Chemist.
1897. Nickel, Herman, c/o The N. K. Fairbank Co., 3rd and Convent Streets, St. Louis, Mo., U.S.A., Chemist.
O.M. Nicol, Dr. W. W. J., 15, Blacket Place, Edinburgh, Chemical Lecturer.
1903. Nicoll, Frank, Jesmond House, Hartman Street, Accrington, Chemist.
1905. Nieghorn, Albert, c/o Canada Chemical Manufacturing Co., Toronto, Canada, Agent.
1900. Nield, J. H., c/o General Chemical Co., P.O. Box 8, Hudson Heights, N.J., U.S.A., Superintendent.
1906. Nielsen, Dr. Carl, c/o General Electric Co., Laboratory, Schenectady, N.Y., U.S.A., Chemist.
1898. Nightscales, Geo., 2, St. James' Parade, Hull, Oil Merchant.
1899. Niboul, Dr. Edw., Waremme, Belgium, Director of the Liège Tannery School.
O.M. Nimmo, Jas., Penshurst, 8, Lawrence Road, South Norwood, S.E., Analytical Chemist.
1885. Nishigawa, T., 12, Yamamato Dori, Nichome, Kobe, Japan, Director of Sulphuric Acid and Soda Works.
1898. Nishikawa, T., c/o Nippon Seimikaisha, Onoda, Nagato, Japan, Chemist.
1904. Noake, Frank, 20, Craddock Street, Wolverhampton, Gas Engineer.
O.M. Nolting, Dr. E., Ecole de Chimie, Mulhouse, Alsace, Germany, Professor of Chemistry.
1905. Norden, Julius, United Chemical Works, 94, Leadenhall Street, London, E.C., Chemical Manufacturer.
O.M. Norman, F. J., Lyndhurst, Higher Runcorn, Cheshire, Chemical Manufacturer.
1900. Norman, Geo. M., Woodbury, N.J., U.S.A., Chemist.
1892. Norman, J. T., 23, Leadenhall Street, London, E.C., Consulting Chemist.
1898. Norris, Albert P., 760, Massachusetts Avenue, Cambridgeport, Mass., U.S.A., Assistant Chemist.
1904. Norris, Cassius W., 612, Commerce Street, Milwaukee, Wis., U.S.A., Tannery Chemist.
1899. Norris, Geo. L., Standard Steel Works, Burnham, Mifflin Co., Pa., U.S.A., Chemist.
1902. North, Barker, Glenholme, Glenholme Road, Manningham, Bradford, Lecturer in Chemistry.
1890. North, E. Gordon N., Technical Chemist.
O.M. Northing, J., The Murrough, Wicklow, Ireland, Technical Chemist.
1905. Norton, Arthur L., 36, Purchase Street, Boston, Mass., U.S.A., Dyestuff Merchant.
1905. Norton, F. A., National Canners' Laboratory, Aspinwall, Pa., U.S.A., Chemist.
O.M. Norton, Dr. S. A., 363, East Town Street, Columbus, Ohio, U.S.A., Professor of Chemistry (Ohio State University).
1887. Norton, Dr. T. H., U.S. Consulate, Smyrna, Turkey-in-Asia, Ph.D., Sc.D., U.S. Consul.
1901. Novarme, John L., 289, Myrtle Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1899. Noyes, Henry, c/o J. C. Lanyon and Sons, Coronation House, Lloyd's Avenue, London, E.C., Engineer.
1901. Noyes, Prof. Wm. A., Melrose Street, Chevy Chase, Md., U.S.A., Editor (J. Amer. Chem. Society).

O

1905. Oakes, Francis J., 2, West 72nd Street, New York City, U.S.A., Dye and Chemical Manufacturer.
1905. Oakes, F. J., jun., 147, Milk Street, Boston, Mass. U.S.A., Secretary, Oakes Manufacturing Co.
1904. Oberländer, Dr. Otto, Laboratory, Chamber of Commerce Buildings, Oxford Court, Cannon Street, London, E.C., Research and Consulting Chemist.
1904. O'Brien, Claude H., Bureau of Central Sugar Mills, Brisbane, Queensland, Supervising Chemist.
1900. O'Brien, Frederick, 87, Dongola Road, Horfield, Bristol, Analytical Chemist.
1906. O'Brien, John W., c/o Grasselli Chemical Co., Grasselli, Ind., U.S.A., Acid Manufacturer.

1905. Oburg, W. F., 33, Broad Street, Boston, Mass., U.S.A., Assistant Treasurer (Merrimac Chem. Co.).
1900. O'Byrne, Leo C., 996, Washington Boulevard, Chicago, Ill., U.S.A., Chemist.
1902. Ockel, Reinhold, 9, Walton New Road, Warrington, Technical Chemist.
1901. O'Connor, Chas. P., 55, Church Street, Montclair, N.J., U.S.A., Analytical Chemist.
1887. Oddie, Jas., School of Mines, Ballarat, Australia, Chemical Lecturer.
1888. Oddy, Robert W., Abbey Street, Toad Lane, Rochdale, Chemist.
1888. Ogata, Saburo, Zobei Shikyoku, Okurasho, Tokyo, Japan, Assayer.
1905. Ogden, Alfred W., Room 1007, 641, Washington Street, New York City, U.S.A., Chemist.
1901. Ogden, Richard L., 314 North Main Street, Bethlehem, Pa., U.S.A., Chemist (U.S. Navy).
1906. Ogilvie, Alex. M., 9, Belmont Drive, Giffnock, Renfrewshire.
1896. Ogilvy, D. J., Gest Street and C. H. and D. R. R., Cincinnati, Ohio, U.S.A., Manufacturing Chemist.
1901. Ogston, Alex. G., Heath Park, near Aberdeen, N.B., Soap Manufacturer.
1903. Ohlenschlager, J. G., jun., 20, St. Dunstan's Hill, London, E.C., Chemical Merchant.
1905. Ohliger, Willard, c/o F. Stearns & Co., Detroit, Mich., U.S.A., Chemist.
1884. Oliver, F., 31, Horsley Hill Road, Westoe, South Shields, Analytical Chemist.
1888. Oliver, Wm. Letts, 101, Vernon Street, Oakland, Cal., U.S.A., Mining Engineer.
1901. Olivier, Dr. Louis, 22, Rue du Général-Foy, Paris, 8e, Directeur (Revue Générale des Sciences).
1905. Ollenbach, D. S., Cordite Factory, Aruvankad, Nilgiris, India, Assistant Government Surgeon.
O.M. Ollerenshaw, S., 96, Davyhulme Lane, Urmston, Manchester, Technical Chemist.
1906. Olmsted, Fred A., 93, Broad Street, Boston, Mass., U.S.A., Chemical Engineer.
1904. Olney, L. A., 118, Riverside Street, Lowell, Mass., U.S.A., Professor of Chemistry and Dyeing.
1903. O'Loughlin, C. C., c/o Pittsburg Reduction Co., Niagara Falls, N.Y., U.S.A., Analyst.
1904. Olshausen, B. A., 1505, St. Andrew's Place, Los Angeles, Cal., U.S.A., Student.
1899. Olsson, Gustav, c/o Hecla Compressed Gas Co., West 3rd Street, Chelsea, Mass., U.S.A., Manufacturing Chemist.
1902. O'Neill, Chas., c/o Bleachers' Association, Ltd., 4, Norfolk Street, Manchester, Chemist and Colourist.
O.M. O'Neill, E. H., 6, Elder Avenue, Crouch End, N., Managing Director.
1905. Ormandy, Dr. W. R., Bewsey Cottage, Warrington, Chemist.
1898. Ormerod, Dr. Ernest, Research Chemist.
1894. Ormerod, John, Globe Leather Works, Castleton, Manchester, Tanner and Currier.
O.M. Orr, A., 35A, Bligh Street, Sydney, New South Wales, Analytical Chemist.
O.M. Orr, J. B., Crossacres, Woolton, Liverpool, Chemical Manufacturer.
1884. Orr, Robert, c/o Jas. Miller, Son and Co., 79, West Nile Street, Glasgow; and (Journals), Kinnaird, Larbert, N.B., Manufacturing Chemist.
1899. Orr, Thos. W., Esperanza Nitrate Co., Taltal, Chile, Chemist.
1905. Osborne, Frank W., Oxford Club, Lynn, Mass., U.S.A., Chemist.
1897. Osborne, Thos. B., Box 164, New Haven, Conn., U.S.A., Chemist.
1900. Osbourne, Jno. P., 572, Alexandra Parade, Dennistoun, Glasgow, Analytical Chemist.
1900. O'Shaughnessy, Francis R., Home Farm, Tyburn, Birmingham, Chemist.
1885. O'Shea, Prof. L. T., Dept. of Applied Science, St. George's Square, Sheffield, Professor of Applied Science (University of Sheffield).
1883. O'Sullivan, J., High Bank, Burton-on-Trent, Brewing Chemist.
1905. Otsuki, Prof. Chiri, 16, Shinsuwachō, Koishikawa, Tokyo, Japan, Professor of Applied Chemistry.
1898. Oushkoff, John P., c/o P. K. Oushkoff and Co., Moscow, Russia, Chemical Manufacturer.
1903. Outwater, Raymond, 1312, B. Street S.W., Washington, D.C., U.S.A., Chemist.
1887. Overtoun, Lord, 7, West George Street, Glasgow, Chemical Manufacturer.
1904. Owen, Halsall, Newholme, Latchford, Warrington, Engineer.
1906. Oxley, Horace F., c/o British Algin Co., and (Journals), Bryn Derwen, Holywell, North Wales, Chemist.
1903. Ozias, Ramon E., 732, Clinton Avenue, Newark, N.J., U.S.A., Assayer.

P

1904. Packard, C. T., Millbank, Bramford, near Ipswich, Manager of Chemical Works.
O.M. Packard, E., Jun., Bramford, near Ipswich, Manufacturer.
1899. Paessler, Dr. Joh., Vorstand der Deutschen Versuchsanstalt für Lederindustrie, Freiberg in Sachsen, Germany, Chemist.
1904. Page, Edwin P., 31, Market Street, Stourbridge, Worcestershire, Chemist.
O.M. Page, F. J. M., 54, Sutherland Street, Pimlico, S.W., Chemical Lecturer.
1907. Page, Leslie, c/o Swift and Co., Soap Works, 37, Medford Street, Somerville, Mass., U.S.A., Chemist.
1886. Pagès, Albert, 34, Boulevard Henri IV., Paris, Technical Chemist.
1892. Paine, Augustus G., 41, Park Row, New York City, U.S.A.; and (Journals) c/o Richard Stutz, Johnsonburg, Pa., U.S.A., President of Paper Making Co.
O.M. Paine, S., Devisdale, Bowdon, Cheshire, Pharmaceutical Chemist.
1902. Pakes, Dr. Walter C. C., Box 4581, Johannesburg, Transvaal, S. Africa, Analyst and Bacteriologist.
1905. Palethorpe, Percy R., The Tobacco Warehousing and Trading Co., 11th and Magnolia Avenue, Louisville, Ky., U.S.A., Chemist and Manager.
1906. Palm, Otto G., 41, Colborne Street, Toronto, Canada, President of Dye and Chemical Co.
1903. Palmenburg, O. W., 80, St. Nicholas Avenue, New York City, U.S.A., Chemist.
1905. Palmer, Dr. Chas. S., 637, Valley Road, Upper Montclair, N.J., U.S.A., Associate Editor.
1902. Palmer, Fred. G., Athelstan Road, Faversham, Kent, Analyst.
1887. Palmer, T. Chalkley, c/o American Dyewood Co., Chester, Pa., U.S.A., Manufacturing Chemist.
1887. Palmer, Thos. C., 98, Commercial Road East, London, E.; and (Journals) Beechwood, Moss Lane, Pinner, Engineer.
1906. Papazzoni, Chas. F., c/o Keystone Powder Manufacturing Co., Emporium, Pa., U.S.A., Chemist.
1902. Paquin, Felix, Memphis, Tenn., U.S.A., Chemist.
O.M. Park, J., Hillside House, 42, Millburn Street, Glasgow, Chemical Manager.
1906. Parke, Jas., School of Practical Science, Toronto, Canada, Chemist.
1888. Parker, Chas. E., Penketh, Warrington, Tanner.
1894. Parker, Chas. E., U.S. Dept. of Agriculture, Bureau of Chemistry, Washington, D.C., U.S.A., Chemist.
1898. Parker, Charles H., Merrills House, March End, Wednesfield, Staffs., Chemist.
1891. Parker, Edw., Thorncliffe, Denton, Manchester, Analytical Chemist.
1906. Parker, Elias G., 238, Grafton Avenue, Newark, N.J., U.S.A., Chemist.
1904. Parker, [illegible], c/o Messrs. Haddock, Parker and Co., 14, [illegible] Street, Liverpool, Chemical Broker.

1894. Parker, Dr. J. Gordon, Herold's Institute, Drummond Road, Bermondsey, S.E., Head of Tanning School.
1897. Parker, Prof. Matthew A., University of Manitoba, Winnipeg, Canada, Professor of Chemistry.
1901. Parker, Richard H., N.Y. Testing Laboratory, Long Island City, N.Y., U.S.A., Analytical Chemist.
O.M. Parker, Thos., Electrical Engineer.
1894. Parker, Thos. J., 25, Broad St., New York City; and (Journals) Bayonne, N.J., U.S.A., Chemical Works Manager.
1903. Parker, Wm. B., Belgrava, Clifton Road, Rugby, Chief Chemist (British Thomson-Houston Co., Ltd.).
1901. Parker, Dr. Wm. Huntington, 177, State Street, Boston, Mass., U.S.A., Chemist (U.S. Appraiser).
1901. Parkes, Albert E., 43, Whitehorse Street, Stepney, E., Analytical Chemist.
1905. Parr, Prof. S. W., University of Illinois, Urbana, Ill., U.S.A., Professor of Applied Chemistry.
1904. Parrett, Ben. C., c/o Struthers Furnace Co., Struthers, Ohio, U.S.A., Analyst.
1898. Parrish, Saml., 80, Grange Avenue, Chapeltown Road, Leeds, Teacher of Chemistry.
1901. Pass, James, Onondaga Pottery Co., Syracuse, N.Y., U.S.A., Pottery Manufacturer.
1902. Patch, Prof. Jas. A., Syrian Protestant College, Beirût, Syria, Professor of Chemistry.
1897. Patchett, Col. Jas., Oakworth, Hadley, Wellington, Salop, Ironmaster.
1901. Paterson, David, Leabank, Rosslyn, Midlothian, Colour Chemist.
1884. Paterson, John, Belle Isle Place, Workington, Cumberland, Mechanical Engineer.
1887. Paton, J. M. C., Messrs. Manlove, Alliott and Co., Ltd., Nottingham, Mechanical Engineer.
1886. Paton, W. Grant, Airlie, Huyton, near Liverpool, Alkali Works Manager.
1901. Patterson, Chas. A., Washburn, Wis., U.S.A., Analytical Chemist.
O.M. Patterson, Geo., c/o The Manbré Saccharine Co., Ltd., Fulham Palace Road, Hammersmith, W., Technical Chemist.
1893. Patterson, Harry J., College Park, Prince George's Co., Md., U.S.A., Agricultural Chemist.
O.M. Patterson, T. L., Maybank, Finnart Street, Greenock, N.B., Sugar Works Manager.
1902. Patterson, Wm. Hamilton, The Sycamores, Ballasalla, Isle of Man, Technical Chemist.
O.M. Pattinson, J., 10, Dean Street, Newcastle-on-Tyne, Consulting Chemist.
O.M. Pattison, Jas., Drimnamona, Kilmalcolm, N.B., Chemical Merchant.
1889. Pattison, Percy J., St. Budeaux, Devonshire Road, Hornchurch, Essex, Technical Chemist.
1905. Patton, Dr. Walter D., United States Glue Co., Milwaukee, Wis., U.S.A., Chemist.
1904. Patz, E. O., 215, Water Street, New York City, U.S.A., Manager, Berlin Aniline Works.
1891. Paul, Jas., H., 19, Glenluce Road, Blackheath, S.E., Analytical Chemist.
1900. Paul, Dr. L. Gordon, Market Hall Chambers, King Street, Huddersfield, Consulting Chemist.
1902. Pay, Walter Herbert, Government Laboratory, Durban, Natal, S. Africa, Chemist and Assayer.
1904. Payne, A. G. C., 63, Plassey Street, Penarth, near Cardiff, Chemist.
O.M. Payne, J. B., 15, Mosley Street, Newcastle-on-Tyne, Manufacturing Chemist.
1906. Payne, J. H., c/o Eastman Kodak Co., Kodak Park Works, Rochester, N.Y., U.S.A., Chemical Engineer.
1898. Pearce, Edw. D., Messrs. T. P. Shepard and Co., P.O. Box 1336, Providence, R.I., U.S.A., Manufacturing Chemist.
1894. Pearce, Jas. Stanley, Clements, Snaresbrook, Essex, Chemical Manufacturer.
1897. Pearce, Richard, c/o G. B. Pearce, The Beeches, Hayle, Cornwall, Smelting Works Manager.
1903. Pearce, Sidney H., P.O. Box 149, Johannesburg, Transvaal, South Africa, Metallurgist.
1883. Pearce, W., M.P., Chemical Works, Bow Common, London, E., Chemical Manufacturer.
1903. Pearcy, A. C., 27, St. Kilda's Road, Stoke Newington, N., Director, Explosives Co.
1903. Pears, Thos., The Laboratory, Soap Works, Isleworth, Soap Manufacturer.
1893. Pearson, Frank P., 8, Richmond Street, Haverhill, Mass., U.S.A., Chemist.
1904. Pease, Fred N., P.O. Box 503, Altoona, Pa., U.S.A., Chemist.
O.M. Pechiney, A. R., Les Rochers, Hyères (Var), France, Chemical Engineer.
1898. Peck, Dr. Ernest L., Claremont, Merrilocks Road, Blundellsands, near Liverpool, Chemist.
1898. Peckham, Stephen F., Room 104, 280, Broadway, New York City, U.S.A., Chemist.
1894. Peden, Jno., 30, Ardgowan Street West, Greenock, N.B., Analytical Chemist.
O.M. Pedler, Sir Alexander, C.I.E., F.R.S., 28, Stanhope Gardens, Queen's Gate, London, S.W., Director of Public Instruction (retired).
1886. Pedler, J. R., 47, Tregunter Road, South Kensington, S.W., Clerk.
1905. Peet, Wm. J., Stockyards Station, Kansas City, Kas., U.S.A., Superintendent.
1903. Peffer, Harry C., c/o Aluminium Co. of America, East St. Louis, Ill., U.S.A., Manufacturing Chemist.
1906 Peile, Henry, Millburn House, Newcastle-on-Tyne, Colliery Owner.
1906. Peirce, Edwin H., c/o American Telephone and Telegraph Co., 125, Milk Street, Boston, Mass., U.S.A., Chemist.
1899. Pell, A., 7, Elphinstone Circle, Bombay, India, Chemist.
1897. Pellew, Chas. E., Columbia University, New York City, U.S.A., Adjunct Professor of Chemistry.
1904. Pelly, Russell George, 63, Rowan Road, Brook Green, Hammersmith, W., Analytical Chemist.
1896. Penney, Mulgrave D., 11, High Street, Hull, Analytical Chemist.
1904. Pennington, Thos. J., c/o Mogul Mining Co., Pluma, South Dakota, U.S.A., Chemist.
1890. Pennock, J. D., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Technical Chemist.
1906. Pennymore, Percy G., Eskbank Iron and Steel Works, Lithgow, N.S.W., Australia, Chemist and Blast Furnace Manager.
1885. Pentecost, S. J., Alexandra Mount, Mapperley Hill, and (Journals), Sherwood Hill Works, Sherwood Rise, Nottingham, Lace Dresser.
1887. Pentermann, H. T., 37, Clifton Crescent, Peckham, S.E., Brewing Chemist.
1892. Peploe, D. H. T., Underriver House, Sevenoaks, Kent.
1899. Peppel, S. Vernon, 1538, North High Street, Columbus, Ohio, U.S.A., Chemist.
1885. Perkin, A. G., F.R.S., 8, Montpelier Terrace, Hyde Park, Leeds, Technical Chemist.
1898. Perkin, Dr. F. Mollwo, Borough Polytechnic Institute, Borough Road, S.E., Head of Chemical Department.
O.M. Perkin, Sir William H., F.R.S., The Chestnuts, Sudbury, Harrow, Research Chemist.
1887. Perkin, Dr. W. H., jun., F.R.S., Fairview, Wilbraham Road, Fallowfield, Manchester, Professor of Chemistry.
1903. Perkins, Frank G., 136, Newton Street, Waltham, Mass., U.S.A., Starch Manufacturer.
1893. Perkins, T. S., 39, Garden Place, Brooklyn, N.Y., U.S.A., Chemist.
1899. Perks, Walter G., (Journals) Glanafon, and (communications) c/o National Explosives Co., Ltd., Hayle, Cornwall, Manufacturer.
1904. Perrott, Bert, County School, Neath, Glamorgan, Demonstrator in Chemistry.
1906. Perrow, Mosby G., Lynchburg, Va., U.S.A.
1901. Perry, Chas. M., 4, Catalpa Road, Providence, R.I., U.S.A., Bleach and Dyeworks Chemist.
1887. Perry, D., Norwood, Lenzie, N.B., Manufacturing Chemist.

1895. Perry, Jos. H., 276, Highland Street, Worcester, Mass., U.S.A., Teacher of Chemistry.

1903. Perry, M. J. T., Australian Drug Co., O'Connell Street, Sydney, N.S.W., Australia, Manufacturing Chemist.

1903. Perry, Robt. Swain, c/o Harrison Bros. and Co., Inc., 35th Street and Grays Ferry Road, and (Journals) Station D., Philadelphia, Pa., U.S.A., President.

1901. Persons, Ashton C., 74, Oak Street, Willimantic, Conn., U.S.A., Chemist.

1897. Peter, Dr. A. H., c/o Zinsser and Co., Hastings-on-Hudson, N.Y., U.S.A., Chemist.

1906. Peterson, Charles A., 104, Front Street East, Toronto, Canada, Chemist.

1893. Pethybridge, Walter, 3, Rhodesia Road, Clapham Rise, S.W., Chemist and Assayer.

1903. Petrie, Dr. Jas. M., The University, Sydney, N.S.W., Australia, Chemist.

1902. Petsche, B. W., 60, Glenwood Avenue, Yonkers, N.Y., U.S.A., Chemist.

1906. Pettee, Chas. L. W., c/o Hartford Laboratory Co., Hartford, Conn., U.S.A., Chemist.

1883. Pettigrew, J., 6, St. Helen's Place, Bishopsgate, London, E.C., Technical Chemist.

1892. Pettigrew, Robt., c/o Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Electro-Chemist.

1902. Pettitt, Alf., 375, State Street, Brooklyn, N.Y., U.S.A., Chemist.

1906. Peucheu, Arthur G., Standard Chemical Co., Ltd., 509, Manning Chambers, Toronto, Canada, Chemical Manufacturer.

1905. Pouchot, A., 129, Crosby Street, New York City, U.S.A., Chemical Manufacturer.

1906. Peverley, Frank, 21, Gladstone Street, Skipton, Yorks, Dyer.

1904. Peyser, Horace F., 68, West 47th Street, New York City, U.S.A., Chemist.

O.M. Peyton, E. P., Chemical Works, Lister Street, Birmingham, Chemical Manufacturer.

1900. Peyton, Wm. C., c/o Peyton Chemical Co., Room 328, Montgomery Block, San Francisco, Cal., U.S.A., Chemist.

1904. Pfahler, H. W., 907, Delaware Avenue, South Bethlehem, Pa., U.S.A., Chemist.

1888. Philip, Arnold, Chemical Laboratory, H.M. Dockyard, Portsmouth, Electro-Metallurgist and Electrical Engineer.

1903. Philipp, Herbert, 84, High Street, Perth Amboy, N.J., U.S.A., Chemist and Electrochemical Engineer.

1886. Phillips, A. G., 11, Essex Villas, Phillimore Gardens, Kensington, W., Barrister-at-Law.

1904. Phillips, Edw. W., c/o Fairmont Coal Co., and (Journals) 800, Gaston Avenue, Fairmont, W. Va., U.S.A., Chemist.

1891. Phillips, G. Brinton, (Journals) 622, Race Street; and (communications) 2007, De Lancey Place, Philadelphia, Pa., U.S.A., Manufacturing Chemist.

O.M. Phillips, Harcourt, Lynwood, Turton, Lancs., Analytical Chemist.

1895. Phillips, S. Chas., 47, Cannon Street, London, E.C., Chemical Engineer.

1904. Phillips, V. C., Haselmere, Morris Avenue, Manor Park, E., Chemist.

1898. Phillips, Wm. H., 100, Milton Avenue, East Ham, E., Soap Works Chemist.

1906. Phipps, Chas. B., Mount Prospect Laboratory, Flatbush Avenue and Eastern Parkway, Brooklyn, N.Y., U.S.A., Chemist.

1883. Phipson, Dr. T. L., Casa Mia, Putney, S.W., Analytical and Consulting Chemist.

1894. Picard, Hugh F. K., 44, London Wall, London, E.C., Metallurgist.

O.M. Pick, Dr. S., Direction der Soda Fabrik, Szczakowa, Galizien, Austria, Chemical Engineer and Manager.

1904. Pickard, Glenn H., c/o The Spencer-Killogg Co., Buffalo, N.Y., U.S.A., Chemist.

1905. Pickard, Greenleaf W., Amesbury, Mass., U.S.A., Electrical Engineer.

1902. Pickard, R. H., Isca, Merlin Road, Blackburn, Teacher and Analyst.

1904. Pickett, Chas. E., 26, East 33rd Street, Bayonne, N.J., U.S.A., Superintendent, Borax Refinery.

1904. Pickup, Edgar H., 348, Great Clowes Street, Higher Broughton, Manchester, Calico Printer.

1888. Pilkington, G., 263, Walmersley Road, Bury, Lancashire, Analytical Chemist.

1893. Pilley, Thos. W., 33, Grove Hill Road, Denmark Hill, S.E., Analytical Chemist.

1894. Pilling, John E., Agnew Villas, 78, Whitegate Drive, Blackpool, Chemist.

1906. Pincott, Emile S., 222, St. James Street, Montreal, Canada, Manager (Nichols Chemical Co. of Canada, Ltd.).

1905. Pinnock, H. T., Beacon House, Dudley Port, Tipton, Chemist.

1883. Pipe, Jas., Messrs. Wm. Henderson & Co., Irvine, N.B., Chemical Manufacturer.

1896. Piper, Walter E., Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.

1905. Pirie, Frank D., Stoneywood Works, Bucksburn, Aberdeenshire, Paper Manufacturer.

1900. Pitman, Jno. R., c/o Laflin and Rand Powder Co., Haskell, N.J., U.S.A., Chemist.

1907. Pitman, Brig.-Gen. John, c/o J. R. Pitman, Haskell, N.J., U.S.A., U.S. Army (retired).

O.M. Pitt, T., 16, Coleman Street, London, E.C., Manufacturing Chemist.

1902. Pittard, Jno., 30, Mansfield Road, Ilford, Essex, Chemical Manufacturer.

1905. Pittock, C. K., Baithney Estate, Saklaspur, Hassan, India, Coffee Grower and Chemist.

1884. Pittuck, F. W., 19, Stratford Grove, Heaton, Newcastle-on-Tyne, Technical Chemist.

1899. Pizey, Jas. H., Bella Vista, 19, Minas de Rio Tinto Prov. de Huelva, Spain, Chemist.

1905. Plath, Dr. F., Deutsche Ton- und Steinzeugwerke, A.-G., Berlinerstrasse 22 B., Charlottenburg, Germany, Managing Director.

1894. Platten, Frank, 12, Montague Road, Edgbaston, Birmingham, Metallurgical Chemist.

1890. Platts, Jno. C., 12, Alton Terrace, Fairfield, Manchester, Metallurgical Chemist.

1896. Plaut, Albert, 120—128, William Street, New York City, U.S.A., Wholesale Druggist.

1888. Playfair, David J., 7, Victoria Crescent, Dowanhill, Glasgow, Manufacturing Chemist.

1907. Playter, Geo. H., 6, Beacon Street, Boston, Mass., U.S.A., Mining Engineer.

1891. Pocklington, Hy., 41, Virginia Road, Leeds, Assurance Co.'s Local Manager.

1901. Pollard, Wm., Museum, Jermyn Street, London, S.W., Chemist (H.M. Geological Survey).

1904. Pollitt, Dr. Geo. P., Winnington, Northwich, Cheshire, Chemist.

1902. Pollitt, Jas. C. T., Church Hill, Solihull, Warwickshire, Managing Chemist.

1893. Pollitt, R. B., Civil Engineer.

1883. Pollock, A., Kirkland, Bonhill, Dumbartonshire, Dyeworks Manager.

1890. Pomeroy, Dr. Chas. T., 55, Broad Street, Newark, N.J., U.S.A., Ink Manufacturer.

1896. Pond, Prof. G. G., State College, Centre Co., Pa., U.S.A., Professor of Chemistry.

O.M. Pond, J. A., 99, Queen Street, Auckland, New Zealand, Analytical Chemist.

1906. Pont, A. Felix du, Box 31, Wilmington, Del., U.S.A., Explosives Manufacturer.

1895. Pont, Pierre S. du, Wilmington, Del., U.S.A., Explosives Manufacturer.

1892. Pope, Frank, c/o The Dunwoody Bros. Soap Co., Denver, Colo., U.S.A., Chemist.

O.M. Pope, S., 35, Victoria Road, Runcorn, Chemical Works Manager.

1899. Pope, Thos. H., The University, Birmingham, Chemist.

1900. Pope, Prof. W. J., F.R.S., Municipal School of Technology, Manchester; and (Journals), Corchester, Bramhall, Cheshire, Professor of Chemistry.
1900. Popplewell, Jos. M., Provan Chemical Works, Provanmill, Glasgow, Chemist.
1899. Porter, A. Felix, 1613, Rodney Street, Wilmington, Del., U.S.A., Chemist.
1896. Porter, Herbert, 80, Lancaster Avenue, Fennel Street, Manchester, Alkali Inspector.
1902. Porter, J. Edw., P.O. Box 785, and 205, W. Genesee Street, Syracuse, N.Y., U.S.A., Chemist.
1906. Porter, John J., Box 551, Staunton, Va., U.S.A., Chemist and Metallurgist.
1901. Porter, Jno. L., New Orleans Sewerage Board, 602, Carondelet Street, New Orleans, La., U.S.A., Chemist.
1904. Portner, Edward G., Robert Portner Brewing Co., Alexandria, Va., U.S.A., Chemist.
1884. Potter, Chas. E., Love Lane Sugar Refinery, Liverpool, Sugar Works Chemist.
1905. Potter, Chas. Ed., c/o City Dairy Co., Ltd., Spadina Crescent, Toronto, Canada, General Manager.
1888. Potter, Chas. J., Heaton Hall, Newcastle-on-Tyne, Cement Manufacturer.
O.M. Potter, E. P., Salwick Hall, near Preston, Alkali Manufacturer.
1906. Potter, Dr. H. Noel, 510, West 23rd Street, New York City, U.S.A., Electrical Engineer.
1905. Potter, N. S., jun., c/o Western States Portland Cement Co., Independence, Kas., U.S.A., Chemist.
1899. Potter, Rowland S., Eastbury, Upland Park Avenue, Loughton, Essex, Chemist.
1900. Potts, Geo. E., 18, Tremont Street, Pottsville, Pa., U.S.A., Explosives Manufacturer.
1900. Pough, Frank H., c/o T. and S. C. White Co., 28, Burling Slip, New York City, U.S.A., Manager.
1889. Powell, A., Ernest, 46, Monton Street, Moss Side, Manchester, Oil Merchant.
1900. Powell, Harry J., 506, Lordship Lane, London, S.E., Glass Manufacturer.
1884. Powell, L. S., The Old Manor House, Ashley, Stockbridge, Hants, Electrician.
1897. Power, Dr. Fred. B., Wellcome Research Laboratories, 6, King Street, Snow Hill, London, E.C., Director.
1902. Powney, Wm. E. F., Department of Mines, Edfu, Upper Egypt., Analytical Chemist.
1900. Pratt, N. P., Laboratory, Atlanta, Ga., U.S.A., Manufacturing Chemist.
1889. Pratt, Walter E., Patchetts, Caton, near Lancaster, Analytical Chemist.
1897. Prentice, Dr. Bertram, Royal Technical Institute, Salford, Lecturer on Chemistry.
1902. Prentice, Dr. David, The Nook, Whitefield Road, Stockton Heath, Warrington, Chemist
1903. Prentice, Jas., Cossipore Sugar Works, Cossipore, Calcutta, India Chemist.
1905. Prentiss, G. L., c/o Parson Manufacturing Co., 299, Broadway, New York City, U.S.A., Treasurer.
1900. Prescott, Saml. C., 739, Boylston Street, Boston, Mass., U.S.A., Instructor in Bacteriology.
1905. Preston, Jas. F., Lowell, Mass., U.S.A., Manufacturing Chemist.
1906. Preston-Jackson, J. W. A., Castleford, Yorkshire, Consulting and Analytical Chemist and Druggist.
O.M. Price, Arthur F., 2503, Broadway, San Francisco, Cal., U.S.A., Analytical Chemist.
1905. Price, Dr. T. Slater, The Technical School, Birmingham, Lecturer on Chemistry.
1904. Prichard, Norman B., Tweed, Ontario, Canada, Superintendent.
1904. Prideaux, E. B. R., 62, Queen Street; and (Journals), Heriot Watt College, Edinburgh, Research Chemist.
1905. Priest, Geo. Wesley, Mansfield, Mass., U.S.A., Manufacturer.
1906. Priestman, A., 17, Falkner Square, Liverpool, Drysalter.
1906. Pring, J. N., Linden Bank, Sandbach, Cheshire, Student.
1899. Prinsen-Geerligs, H. C., Pekalongan, Java, Netherlands Indies, Director of Sugar Cane Experimental Station.
1893. Pritchard, Edgar J., 5, Cumberland Gate, Kew, Surrey, Works Manager.
1903. Pritchard, Philip M., Chief Engineer's Office, United Alkali Co., Ltd., Widnes, Engineer.
1896. Prochazka, Dr. Geo. A., 138, West 13th Street, New York City, U.S.A., Colour Manufacturer.
O.M. Procter, Prof. H. R., The University, Leeds; and (Journals) Rowangarth, Ben Rhydding, near Leeds, Yorks., Lecturer on Tanning.
1884. Procter, J. W., Skeldergate Bridge, York, Manure Manufacturer.
1890. Proctor, Miss Anne J., Free Library, Widnes, Librarian.
O.M. Proctor, C., 43A, London Road, Forest Hill, S.E., Analytical Chemist.
1901. Propach, C., 224, Randolph Street, Chicago, Ill., U.S.A., Colour Merchant.
1894. Proude, Jas., 30, Cromwell Terrace, Halifax, Yorks., Soap Works Chemist and Manager.
1907. Puckhaber, Geo. C., 165, Rodney Street, Brooklyn, N.Y., U.S.A., Glue Maker.
1906. Pudney, Sydney H., 156, Bellwood Avenue, Toronto, Canada, Foreman.
1905. Pugh, John V., Ginting House, Allesley, near Coventry, Works Director (Rudge Whitworth, Ltd.).
1899. Pullar, Edmund, Keirfield, Bridge of Allan, N.B., Manufacturer.
1894. Pullar, Herbert S., Pullar's Dyeworks, Perth, N.B., Dyer.
O.M. Pullar, Sir Robert, M.P.; Journals to Jas. Craigie, Sandeman Public Library, Perth, N.B., Dyer.
O.M. Pullar, R. D., Pullar's Dyeworks, Perth, N.B., Dyer.
1903. Pullin, Sydney R., Attasi Mines, Princisu, Dunkwa Station, Sekondi, Gold Coast Colony, Chemist.
1902. Puntan, H. H. C., 10, London Chambers, Durban, Natal, Public Analyst.
1894. Purdie, Dr. Thos., F.R.S., 14, South Street, St. Andrews, N.B., Professor of Chemistry.
1906. Purves, Geo., The Refinery, Canal Bank, St. Ambriose Street, St. Henri de Montreal, Canada, Chemist and Works Manager.
1905. Pyman, Dr. Frank Lee, The Oaks, Hitchin, Herts., Chemist.

Q

1903. Queeny, Jno. F., (Journals) Monsanto Chemical Works, and (communications) 1810, South 2nd Street, St. Louis, Mo., U.S.A., Chemical Manufacturer.
1905. Queiroz, Dr. Luiz M. Pinto de, Caixa 255, Sao Paulo, Brazil, Manufacturing Chemist.
1903. Queneau, Augustin L., c/o New Jersey Zinc Co., South Bethlehem, Pa., U.S.A., Mining Engineer.
1887. Quibell, Oliver, Shalem Lodge, Newark-on-Trent, Manure Manufacturer.
1902. Quinan, Kenneth B., c/o De Beers Explosives Works, Somerset West, C.C., South Africa, Chemist.
1897. Quinan, Wm. R., (Journals) General Manager, De Beers Explosives Works, Dynamite Factory, Cape Colony, South Africa; and (subscriptions) c/o De Beers Consolidated Mines, 15, St. Swithin's Lane, E.C., Superintendent (Powder Works).
1897. Quirk, Jno. S., Lead Smelting Works, St. Helens, Lancs., Manager.

R

1898. Radcliffe, Lionel G., 431, Stretford Road, Manchester, Chemist.
1904. Rademacher, Dr. Ferdinand, Prag-Carolinenthal, Austria, Chemical Manufacturer.

1900. Radley, Ernest G., 49, Ernest Street, West Norwood, S.E.
1895. Raegener, Louis C., 141, Broadway, New York City, U.S.A., Patent Lawyer.
1906. Rafft., Dr. Albert K., Moosic, Pa., U.S.A., Chemist.
1901. Ralston, Wm., 3, Windsor Terrace, Linthouse, Glasgow, Government Chemist.
1902. Ramsay, A. Alexander, Laboratory, Department of Agriculture, 136, George Street, Sydney, N.S.W., Australia, Assistant Chemist.
O.M. Ramsay, Sir William, K.C.B., F.R.S., University College, London, W.C.; Journals to 19, Chester Terrace, N.W., Professor of Chemistry.
1885. Ramsay, W., c/o Cammell, Laird and Co., Ltd., Birkenhead Ironworks, Birkenhead, Chemist and Assayer.
1898. Ramsden, Andrew, York Villa, Walmersley Road, Bury, Lancs., Sugar Works Manager.
1906. Ranck, Samuel H., Ryerson Public Library Building, Grand Rapids, Mich., U.S.A. Librarian.
1901. Ransom, Francis, The Chilterns, Hitchin, Herts., Manufacturing Pharmaceutical Chemist.
1905. Ransom, H. B., 78, St. George's Square, London, S.W., Engineer.
1904. Rapelje, Walter S., 957, Liberty Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1898. Raschen, Dr. Julius, The Highlands, Runcorn, Cheshire, Consulting Chemist (United Alkali Co.).
1905. Raschig, Dr. F., Ludwigshafen a/Rhein, Germany, Manufacturing Chemist.
1893. Ratcliff, Frank D., The Cottage, Green Hill, Bromsgrove, Worcestershire, Vinegar Brewer.
1904. Ratcliffe, C. F., c/o Brotherton and Co., Ltd., Provan Chemical Works, Millerston, Glasgow, Tar Distiller.
1904. Ratcliffe, Mrs. F. A., The Orchard, Dulwich Common, West Dulwich, S.E.
1898. Ratcliffe, Walter, 21, Mawdsley Street, Bolton, Analytical Chemist.
1895. Rau, Dr. H. M., 130-132, Pearl Street, New York City, U.S.A., Chemist.
1901. Rauter, Dr. G., Cauerstrasse, 2, Charlottenburg, I, bei Berlin, Germany, Engineering Chemist.
1901. Rawlins, Herbert J. L., The Cottage, Rainhill, Lancashire, Managing Director.
1903. Rawolle, Frederick C., c/o Marx and Rawolle, 100, William Street, New York City, U.S.A., Chemist.
O.M. Rawson, Chris., 2, Melbourne Place, Bradford, Consulting Chemist.
1906. Raymond, R. S., Marshall's Co-operative Breweries Co., Ltd., Paddington, Sydney, N.S.W., Australia, Brewer.
1895. Read, E. J., St. Ives, The Avenue, Gravesend, Kent, Analyst.
1890. Reade, Thos., Sebright House, Tettenhall Wood, Wolverhampton, Manufacturing Chemist.
O.M. Readman, Dr. J. B., Mynde Park, Hereford, Analytical and Consulting Chemist.
1907. Rebhun, Frank E., c/o Pennsylvania Salt Manufacturing Co., Natrona, Pa., U.S.A.
1902. Redfern, C. G., 4, South Street, Finsbury, London, E.C., Patent Agent.
1890. Redgate, J. G., Traffic Street, Nottingham, Aërated Water Manufacturer.
O.M. Redwood, Sir Boverton, 4, Bishopsgate Street Within, London, E.C., Petroleum Expert.
1884. Redwood, Ityd J., The Chestnuts, Erith Road, Bexley Heath, Kent, Technical Chemist.
1887. Redwood, Robt., 4, Bishopsgate Street Within, London, E.C., Secretary.
1891. Redwood, T. Horne, Olveston, Sedlescombe Road, St. Leonard's-on-Sea, Analytical Chemist.
1886. Rée, Dr. A., 15, Mauldeth Road, Withington, Manchester, Aniline Dye Manufacturer.
1884. Reed, Albert E., The Grange, Leigham Court Road, Streatham, S.W., Paper Works Chemist.
1902. Reed, Hebert C., c/o Stamford Manufacturing Co., Stamford, Conn., U.S.A., Chemist.
1905. Reed, Herbert W., 153, Milk Street, Boston, Mass., U.S.A., Dye Salesman.
1895. Reed, Dr. J. Hastings, Hambledon Mill, via Cairns, North Queensland, Sugar Manufacturer.
1906. Reed, William, Bridge House, Bridge Road, Millwall, E., Foreman (Desilverising Works).
1893. Reekie, J. A., Woodhouse, Hayfield, Derbyshire, Calico Printer's Colour Mixer.
1883. Reeks, T. H., 106, Queen Victoria Street, London, E.C., Analytical and Consulting Chemist.
1897. Rees, W. H., c/o Alameda Sugar Co., Alvarado, Cal., U.S.A., Chemist.
1906. Rees, Walter J., c/o Chann, Bros. and Co., Ltd., Smethwick, near Birmingham, Glass Works Chemist.
1900. Reese, Dr. Chas. L., c/o Repauno Chemical Co., Chester, Pa., U.S.A., Chemist.
1897. Reid, Andrew, 37, Mount Stuart Street, Shawlands, Glasgow, Chemist.
1906. Reid, James, Moffat Mills, Airdrie, N.B., Chemist.
1905. Reid, Dr. John H., 11, Glover Street, Birkenhead, Chemist.
1907. Reid, Robert, Agencia de Tharsis, Huelva, Spain, Analytical Chemist.
1896. Reid, Robt., Oil Mills, Horbury Bridge, near Wakefield, Chemical Student.
1895. Reid, T. Anderson, c/o Johnsen, Jörgensen, and Wettre, 38, Victoria Buildings, Manchester, Works Manager.
O.M. Reid, Walter F., Fieldside, Addlestone, Surrey, Technical Chemist.
1893. Reid, Wm., Jun., Bombay Dyeworks, Dadur, Bombay, India, Dyer.
1904. Reinherz, Otto, 9, Heaton Grove, Bradford, Yorks., Chemist.
1906. Reinhold, Gustave, 11, Hervey Road, Blackheath, S.E., Works Manager.
1898. Reitmeyer, Robt. E. D., 63, Crutched Friars, London, E.C., Chemical Merchant.
1904. Remington, Prof. Joseph P., 1832, Pine Street, Philadelphia, Pa., U.S.A., Author, U.S. Pharmacopœia.
1900. Remington, J. Stewart, Aynsome, Grange-over-Sands, R.S.O., Lancs., Consulting Chemist.
1903. Remsen, President Ira, Johns Hopkins University, Baltimore, Md., U.S.A., President.
1884. Renaut, F. W., 17, Emanuel Avenue, Friar's Park, Acton, W., Secretary.
1905. Render, Fredk., Underley House, Whitefield, Manchester, Explosives Manufacturer.
O.M. Rennie, Dr. E. H., University of Adelaide, South Australia, Professor of Chemistry.
1901. Renwick, Frank F., Cromer Villa, Warley Road, Brentwood, Essex, Chemist (Photographic Works).
1907. Reoch, Robert A. S., Cocheco Manufacturing Co., Dover, N.H., U.S.A., Printworks Superintendent.
1894. Rettie, Theodore, 16, Great King Street, Edinburgh, Metallurgical Chemist.
1895. Reubens, Chas. M., 143, West 111th Street, New York City, U.S.A., Chemist.
1905. Revis, Cecil, 77, King Street West, Hammersmith, W., Analyst.
O.M. Reynolds, Dr. J. Emerson, F.R.S., 29, Campden Hill Court, Kensington, W., Professor of Chemistry.
1904. Rhett, Edmund, American Ether Co., Richmond, Va., U.S.A., Superintendent.
O.M. Rhodes, E., c/o Thos. Vickers and Sons, Widnes, Technical Chemist.
1892. Rhodes, P. J., Church Bridge House, Accrington, Dye and Print Works Manager.
1902. Rhodin, B. E. F., Sault Ste. Marie, Ont., Canada, Chemical Engineer.
1905. Richard, Francis C., Range Quarters, Mount Morgan, Queensland, Assayer (Mt. Morgan G.M. Co.).
1889. Richards, Edgar, 60, Ayrault Street, Newport, R.I., U.S.A., Analytical Chemist.
1888. Richardson, Clifford, New York Testing Laboratory, Long Island City, N.Y., U.S.A., Chemical Engineer.

1903. **Richardson, F. J.**, Chemical Works, Ringsend Docks, Dublin, Ireland, Chemical Manure Manufacturer.
1894. **Richardson, F. W.**, City Analyst's Office, Bradford; and (Journals) Oak Lea, Menston-in-Wharfedale, Yorkshire, Analytical Chemist.
1900. **Richardson, Jno. H.**, c/o H. D. Pochin and Co., Ltd., Salford, Manchester, Manager.
1905. **Richardson, L. G.**, Russell Buildings, 10, Leeds Street, Bradford, Yorks., Chemist.
1889. **Richardson, S. M.**, 415, Main Street, Bonhill, N.B., Analytical Chemist.
1891. **Richardson, Walter W.**, Aldingham, Park View Crescent, Roundhay, Leeds, Manufacturing Chemist.
1903. **Richardson, Wm.**, 2, Thornfield Road, West Park, Headingley, Leeds, Drysalter.
1900. **Richardson, Wm. Derrick**, 4306, Forestville Avenue, Chicago, Ill., U.S.A., Chemist (Swift and Co.).
1894. **Richardson, Wm. H.**, Newsky Thread Mills, Malaja Bolotnaja, St. Petersburg, Russia, Textile Chemist.
1904. **Richardson, Wm. S.**, 201, High Street, Lincoln, Chemical Manure Manufacturer.
1886. **Richmond, H. D.**, 8, Woodfield Road, Ealing, W., Chief Chemist (Aylesbury Dairy Co.).
1898. **Richmond, Jno. R.**, 14, North Road, West Kirby, Cheshire, Alkali Works Manager.
1901. **Richmond, Sylvester O.**, 12, Ambleeote Road, Grove Park, Lee, S.E., Analytical Chemist.
1907. **Ricketts, Guy D.**, 25, Huskisson Street, Liverpool, Lecturer on Metallurgy (Liverpool University).
1886. **Riddell, R.**, 87, Horninglow Street, Burton-on-Trent, Brewer.
1894. **Ridding, Howard C.**, School of Mines, Clinton Road, Redruth, Cornwall, Principal.
1884. **Rideal, Dr. Samuel**, Laboratory, 28, Victoria Street, Westminster, S.W., Consulting Chemist.
1905. **Ridge, H. M.**, Owton Manor, Seaton Carew, Co. Durham, Mining Engineer.
O.M. **Ridsdale, C. H.**, Ravenscroft, Roman Road, Linthorpe, Middlesbrough, Analytical Chemist.
1899. **Riederer, Emil J.**, c/o Eastern Dynamite Co., Forcite Works, Landing, N.J., U.S.A., Works Chemist.
1902. **Riederer, Dr. Herman S.**, 251, West 95th Street, New York City, U.S.A., Chemist.
1907. **Rigg, Gilbert**, c/o New Jersey Zinc Co., Palmerton, Carbon Co., Pa., U.S.A.
1892. **Riker, Jno. J.**, 46, Cedar Street, New York City, U.S.A., Merchant.
O.M. **Riley, E.**, 2, City Road, Finsbury Square, London, E.C., Metallurgical Chemist.
O.M. **Riley, J. E.**, c/o John Riley & Sons, Hapton, near Accrington, Chemical Manufacturer.
1884. **Riley, Jno.**, Mayfield, Thornliebank, near Glasgow, Print Works Manager.
1905. **Riley, Louis J.**, 8, Newton Road, London, W., Chemist.
1904. **Riley, W. A.**, Hazeldene, College Road, Norwich, Brewer.
1899. **Rink, Arnold**, 11, Bridgewater Street, Barbican, London, E.C., Tannin Extract Manufacturer.
1889. **Rintoul, Wm.**, 4, Sewardstone Road, Waltham Abbey, Essex, Explosives Chemist.
1901. **Ripley, Philip F.**, 48, Central Street, Andover, Mass., U.S.A., Chemist.
1885. **Ritson, T. N.**, 1, West Cliff Villas, West Cliff Road, Ramsgate, Gas Engineer.
1906. **Rivière, Harry V.**, 232, Lafayette Street, Salem, Mass., U.S.A., Chemist and Leather Superintendent.
O.M. **Rix, W. P.**, Frocester House, Kinglake Road, Egremont, Cheshire, Potter.
1890. **Roberts, C. F.**, Linfitts, Delph, *via* Oldham, Chemical Merchant.
O.M. **Roberts, F. G. Adair**, Oak Hill Lodge, Frognal, N.W., Chemical Manufacturer.
1901. **Roberts, H. E. U.**, 14, Newton Road, Faversham, Kent, Chemist (Cotton Powder Co., Ltd.).
1885. **Roberts, R. Wightwick**, 22, Calle Arturo Prat, Valparaiso, Chili, Analytical and Consulting Chemist.
1900. **Roberts, Wm. Brittain**, Wilderspool House, Warrington, Brewer and Analyst.
1902. **Roberts, Wm. H.**, Lynwood, Wellington Field, Wavertree, Liverpool, Analytical Chemist.
1902. **Robertshaw, Chas. D.**, c/o Chas. Price and Co., Oilworks, Belvedere, Kent, Analytical Chemist.
1891. **Robertson, Alex. A.**, Riversdale, Cressington Park, Liverpool, Technical Chemist.
1897. **Robertson, Andrew, J.**, 2, North Ninth Street, Richmond, Va., U.S.A., Analytical Chemist.
1903. **Robertson, Fred.**, 128, Wellington Street, Glasgow, Analytical Chemist.
1900. **Robertson, Jas.**, 6, Windsor Terrace, Lefroy Street, Coatbridge, N.B., Analytical Chemist.
1891. **Robertson, Dr. Robt.**, 9, Sewardstone Road; (Journals) Royal Gunpowder Factory, Waltham Abbey, Essex, Analytical Chemist.
1905. **Robertson, Robt.**, 135, Pearl Street, Boston, Mass., U.S.A., Dyestuff Salesman.
1897. **Robinson, Clarence J.**, Westerleigh, West New Brighton, N.Y., U.S.A., Chemist.
1900. **Robinson, Edw. B.**, 2, Westcott Street, Hull, Oil Distiller.
1904. **Robinson, Prof. Franklin C.**, Bowdoin College, Brunswick, Maine, U.S.A., Professor of Chemistry.
1902. **Robinson, Hy. Fishwick**, Culcheth Chemical Works, Newton Heath, Manchester, Manufacturing Chemist.
O.M. **Robinson, H. H.**, 75, Finborough Road, West Brompton, S.W., Analytical Chemist.
1907. **Robinson, Herbert W.**, Robinson Bros., Ltd., Ryders Green, West Bromwich, Staffordshire, Tar Distiller.
O.M. **Robinson, Jno.**, 8, Albert Road, Widnes, Chemical Engineer.
O.M. **Robinson, Jos.**, Farnworth, Widnes, Chemical Manufacturer.
1887. **Robinson, Thomas**, (Journals) 401, West Street, Glasgow; and (communications), The Villa, Nitshill, N.B., Chemical Works Manager.
1902. **Robitschek, Carl**, 200, Worth Street, New York City, U.S.A., Scientific Brewer.
1884. **Rodger, Edw.**, 1, Clairmont Gardens, Glasgow, W.
1904. **Rodger, Robert**, Government Laboratory, Clement's Inn Passage, Strand, London, W.C., Chemist.
1905. **Rodger, R. L.**, Suffolk House, Cannon Street, London, E.C., Manager (Pena Copper Mines).
1904. **Roeber, Dr. E. F.**, 114, Liberty Street, New York City, U.S.A., Editor, "Electrochemical Industry."
1903. **Roelofsen, Dr. J. A.**, c/o Coal Distillation Co., Middlesbrough, Yorks., Works Manager.
1905. **Rogers, Dr. Allen**, Pratt Institute, Brooklyn, N.Y., U.S.A., Research Chemist.
1900. **Rogers, Geo. J.**, Wallaroo Smelting Works, South Australia, Chemist.
1890. **Rogers, Harry**, 5, Stoke Newington Common, London, N.
1899. **Rogers, John**, Ardeer Factory, Stevenston, Ayrshire, N.B., Chemist.
1907. **Roller, Frank R.**, 525, 31st Street, Oakland, Cal., U.S.A., Powder Works Superintendent.
1898. **Roller, H. C.**, Verona, and Riversdale Avenues, Newark, N.J., U.S.A., Superintendent.
1899. **Rollin, Chas.**, Bylton, East Jarrow-on-Tyne, Chemical Manufacturer.
O.M. **Rollin, J. C.**, 1, St. Nicholas Buildings, Newcastle-on-Tyne, Chemical Manufacturer.
1905. **Romanes, J. W.**, Minas de Rio Tinto, Huelva, Spain, Chemical Engineer.
1898. **Roode, Rudolf de**, International Paper Co., Glens Falls, N.Y., U.S.A., Chemist and Superintendent.
O.M. **Roscoe, Sir Henry, F.R.S.**, 10, Bramham Gardens, South Kensington, S.W., Consulting Chemist.
1901. **Roscow, Jas.**, 471, Park Avenue, Paterson, N.J., U.S.A., Colourist and Chemist.
1893. **Roscow, Jno. F.**, P.O. Box 417, Boonton, N.J., U.S.A., Print Works Chemist.
1899. **Roscow, Wm.**, 24, Prince Street, Pawtucket, R.I., U.S.A., Analytical Chemist.

1900. Ross, Jnº, Wicken House, Stretton, near Warrington, Technical Chemist.
1901. Ross, Jno. Leonard, Gorton Brook Chemical Works, Manchester, S.E., Chemist.
1902. Rosebrugh, Prof. T. K., 666, Spadina Avenue, Toronto, Canada, and (Journals) 203, Kirk Avenue, Syracuse, N.Y., U.S.A., Professor of Electrical Engineering.
1904. Rosenblatt, A. H., Chemist.
1897. Rosengarten, Dr. Geo. D., 1700, Fitzwater Street, Station D, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1905. Rosenhain, Walter, Park View, Park Road, Teddington, Chemist and Metallurgist.
1896. Rosenheim, Dr. Otto, 68, Belsize Park Gardens, Hampstead, N.W., Research Chemist.
1887. Ross, Alex. J. J., Tayavalla, Falkirk, N.B., Chemical Manufacturer.
1893. Ross, Arthur, 1, Glengall Road, Old Kent Road, London, S.E., Analytical Chemist.
1900. Ross, Raymond, Public Analyst's Office, Burnley, Lancashire, Analytical Chemist.
1906. Rossi, Auguste J., c/o Roessler Hasslacher Chemical Co., Perth Amboy, N.J., U.S.A., Mining Engineer.
1906. Rossi, Louis M., c/o Perth Amboy Chemical Works, Perth Amboy, N.J., U.S.A., Mining Engineer.
1906. Rossiter, E. C., 4, Park Road, West Smethwick, Birmingham, Chemical Engineer.
1888. Rothwell, C. F. Seymour, Photographic Works, Mobberley, Cheshire, Chemist.
1905. Rothwell, Robert R., 48, George Street, Moss Side, Manchester, Chemistry and Physics Teacher.
O.M. Rottenburg, Paul, Castle Chambers, 55, West Regent Street, Glasgow, Chemical Merchant.
1899. Rouse, H. W., 62, Russell Road, Custom House, E., Foreman (Sulphuric Acid Works).
1903. Rouse, Wm., 25, Albert Street, Alexandria, Dumbartonshire, Chemist.
1906. Rowell, Herbert W., c/o Locke, Lancaster and Co., Ltd., Bridge Road, Limehouse, E., Analytical Chemist.
O.M. Rowland, W. L., 4800, Chester Avenue, Philadelphia, Pa., U.S.A., Chemist.
1904. Rowley, Ernest W., Chemical Laboratory, Locomotive Department, North Eastern Railway, Gateshead-on-Tyne, Analytical Chemist.
1901. Rowley, Walter Eugene, c/o Schoellkopf, Hartford and Hanna Co., 100, William Street, New York City, U.S.A.
1904. Rowling, S. R., 1, Beechwood, Kendal, Westmoreland, Chemist.
1896. Royal-Dawson, H., c/o Messrs. Peyton & Son, Chemical Works, Lister Street, Birmingham, Chemist.
1898. Royle, Chas. L., c/o Parry and Co., Samalkot, Godaveri District, Madras, India, Sugar Chemist.
1898. Royle, Thos. H., (Journals) 12, Barfield Villas, George Lane, Woodford, Essex, and (communications) Bareilly, United Provinces, India, Chemist.
O.M. Royse, S. W., St. Andrew's Chambers, 20, Albert Square, Manchester, Chemical Engineer.
1902. Rücker, Dr. Hermann von, 675, Potomac Avenue, Buffalo, N.Y., U.S.A., Chemist.
1896. Ruddock, Fred. G., Corporation Street, Warrington, Analytical Chemist.
1895. Rudge, Alfred, Sutton Alkali Works, St. Helens, Lancs., Analytical Chemist.
1904. Ruef, Harry H., c/o The Warner Chemical Co., Carteret, N.J., U.S.A., Chemist.
1884. Ruffle, Jno., Musley, Ware, Herts., Consulting Chemist and Electrician.
1905. Rüger, Richard, 8, Alroy Road, Anfield, Liverpool, Chemist.
1898. Ruhl, Louis, c/o Roessler and Hasslacher Chemical Co., P.O. Box 1999, 100, William Street, New York City, U.S.A., Chemical Merchant.
O.M. Rumble, C., Belmont Works, Battersea, London, S.W., Candle Works Chemist.
1899. Rumbold, Wm. R., 47, Watling Street, London, E.C., Electro-Metallurgist.
1895. Rump, Ernst, The Leeds Phosphate Works, Hunslet, Leeds, Manager.
1903. Runting, D. A., Moreland Grove, Coburg, Melbourne, Vic., Australia, Assayer.
1903. Runyan, Elmer G., Hutchins Building, Washington, D.C., U.S.A., Chemist and Gas Inspector.
1899. Rushby, Wm., Broomfield House, Batley, Yorks., Analyst.
1906. Russell, David, Cadham, Markinch, Fife, Scotland, Paper Maker.
1884. Russell, Jno., Anchor Brewery, Britten Street, Chelsea, London, S.W., Brewer.
O.M. Russell, Dr. W. J., F.R.S., 34, Upper Hamilton Terrace, London, N.W., Professor of Chemistry.
1901. Rust, Robt. R., 1315, Fourth Street, Peru, Ill., U.S.A., Chemist.
1905. Ruttan, Prof. R. F., Medical Faculty, McGill University, Montreal, Canada, Professor of Chemistry.
1905. Ryan, Prof. F. G.; (Journals) c/o Parke, Davis and Co., Detroit, Mich., U.S.A., and (subscriptions) c/o Parke, Davis and Co., 111, Queen Victoria Street, London, E.C., Manufacturing Chemist.
1906. Ryan, Ironæus F., 452, Fairmount Avenue, Jersey City, N.J., U.S.A., Chemist.
1905. Ryland, Chawner, 53, Park Road, Aston, Birmingham, Brewer and Chemist.

S

1895. Saalfeld, Adolphe, 2, South King Street, Manchester, Chemical Merchant.
1895. Saarbach, Dr. L., 114, Pearl Street, New York City, U.S.A., Consulting Chemist.
1905. Sabin, Alvah H., 432, Sandford Avenue, Flushing, N.Y., U.S.A., Chemist, Varnish Works.
1883. Sadler, A. E., Sand Hall, Ulverston, Lancashire, Manufacturing Chemist.
O.M. Sadler, Sir Samuel A., Middlesbrough-on-Tees, Colour Manufacturer.
1884. Sadtler, Dr. S. P., 145, North 10th Street, Philadelphia, Pa., U.S.A., Consulting Chemist.
1896. Sadtler, Dr. S. S., 29, South 10th Street, Philadelphia, Pa., U.S.A., Chemist (U.S. Customs).
1905. Safford, E. Brigham, Albuquerque, New Mexico, U.S.A., Chemist.
1897. Sage, C. Edward, 160—162, Kennington Park Road, London, S.E., Consulting Chemist.
1907. Saiki, Kenkichi, 38, West 68th Street, New York City, U.S.A., Chemist.
1884. Salamon, A. Gordon, 1, Fenchurch Avenue, London, E.C., Consulting Chemist.
1885. Salamon, Jno., Rainham, S.O., Essex, Manufacturing Chemist.
1884. Salis-Mayenfeld, Dr. E. von., 9, Macpherson Terrace, Albany, N.Y., U.S.A., Technical Chemist.
1902. Salm, Louis N., 22, Cliff Street, New York City, U.S.A. Chemist.
1902. Salter, M. J., Greyrick House, Mickleton, Campden, Gloucestershire, Analytical Chemist.
1905. Sammet, Dr. G. Victor, 68, Northampton Street, Boston, Mass, U.S.A., Chemist.
O.M. Samuel, W. Cobden, 66, Croxted Road, West Dulwich, S.E., Analytical Chemist.
1896. Samuelson, Francis A. E., Sir B. Samuelson and Co., Ltd., Middlesbrough, Ironmaster.
1904. Sand, Dr. Henry J. S., University College, Nottingham, Lecturer and Demonstrator.
1906. Sanders, J. McConnell, c/o Direccion General de Aduanas, Palacio Nacional, Mexico, D. F., Analytical Chemist.
1902. Sanders, Warren W., c/o Larkin Soap Co., Buffalo, N.Y., U.S.A., Chemist.
1895. Sanderson, John, c/o B. S. Cohen, Ltd., 15, Clerkenwell Close, London, E.C., Chemist.
1898. Sanderson, T. C., Duboise Avenue, West New Brighton, N.Y., U.S.A., Chemical Engineer.

O.M. Sanford, P. Gerald, 20, Cullum Street, London, E.C., Public Analyst and Consulting Chemist.

1904. Sanger, Prof. Charles Robt., Harvard College, Cambridge, Mass., U.S.A., Professor of Chemistry.

1890. Saniter, E. H., Strafford Villa, Moorgate, Rotherham, Analytical Chemist.

1901. Sargent, Dr. Geo. W., Carpenter Steel Co., Reading, Pa., U.S.A., Chemist and Metallurgist.

1903. Saunders, Lewis E., c/o Norton Emery Wheel Co., Niagara Falls, N.Y., U.S.A., Electro-Chemical Engineer.

1896. Saunders, Walter M., 20, Dewey Street, Olneyville, R.I., U.S.A., Analytical Chemist.

1895. Savage, Arthur E., Charles Street, Elsternwick, Victoria, Australia, Metallurgist.

1895. Sawers, Wm. D., 1, Athole Gardens Place, Glasgow, Chemist.

1903. Sawin, Luther R., Mt. Kisco Laboratory, Mount Kisco, N.Y., U.S.A., Bacteriologist.

1901. Sawyer, Dr. Harris E., c/o Felton and Son, 524, East Second Street, South Boston, Mass., U.S.A., Chemist.

1898. Saxe, Sigmond, 107, Manhattan Avenue, New York City, U.S.A., Manufacturing Chemist.

1895. Sayer, Harry, 5, Orchard Road, High Barnet, Herts., Metallurgical Chemist.

1890. Sayers, Jos. J., Nobel Villa, Stevenston, Ayrshire, Explosives Chemist.

1895. Scales, F. Shillington, "Jersey," St. Barnabas Road, Cambridge.

1899. Schaak, Dr. Milton J., 108, Penn Street, Brooklyn, N.Y., U.S.A., Chemist.

O.M. Schack-Sommer, Dr. G., 48, Marlborough Mansions, Victoria Street, London, S.W., Sugar Refiner.

1899. Schaefer, Dr. L., Maywood, N.J., U.S.A., Manufacturing Chemist.

1903. Schanche, Herman G., 3401, Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemist.

1906. Scheffer, Heinrich, 7, Conyngham Road, Rusholme, Manchester, Chemical Apparatus Manufacturer.

1903. Scheidel, Dr. Aug., Union Club, Sydney, N.S.W., Australia, Managing Director.

1880. Schellhaas, Henry Alf., Thornhill, Beach Road, Hartford, Northwich, Mechanical Engineer.

1904. Schenck, Henry, 15, University Place, New York City, U.S.A.

1894. Schidrowitz, Dr. P., 57, Chancery Lane, London, W.C., Research Chemist.

1895. Schieffelin, Dr. W. Jay, 841, Southern Boulevard, New York City, U.S.A., Manufacturing Chemist.

1901. Schieren, G. Arthur, Dixie Tannery, Bristol, Tenn., U.S.A., Mechanical Engineer and Tanner.

1905. Schill, Dr. Emil, c/o G. Siegle Co., 79, Duane Street, New York City, U.S.A., Chemist.

1902. Schlegel, Jno. Wm., cor. Main and Toledo Avenues, Elmhurst, Long Island, N.Y., U.S.A., Chemist.

1893. Schleicher, Francis J., 38, West Tenth Street, Long Island City, N.Y., U.S.A., Technical Chemist.

1902. Schlesinger, Basil E., 92, Mount Vernon Street, Boston, Mass., U.S.A., Chemist.

1901. Schlichting, Emil, 1716, Chestnut Street, Philadelphia, Pa., U.S.A., Chemist.

1905. Schmidt, Herman B., 2523, Essex Place, W.W.H., Cincinnati, Ohio, U.S.A., Manufacturing Chemist.

1906. Schmidts, J., Cross Street, Burton-on-Trent, Works Manager.

1907. Schmitt, Charles A., The Carter's Ink Co., 172, Columbus Avenue, Boston, Mass., U.S.A., Chemist.

1906. Schneible, Joseph, 14th Floor, Rector Building, Chicago, Ill., U.S.A., Chemical Engineer.

1901. Schneider, Edw. J., c/o Union Carbide Co., Niagara Falls, N.Y., U.S.A., Chemist.

1905. Schneider, Dr. F. G., Continental Color and Chemical Co., 32, India Street, Boston, Mass., U.S.A., Technical Chemist.

1898. Schniewind, Dr. F., c/o United Coke and Gas Co., 17, Battery Place, New York City, U.S.A., Chemist.

1904. Schniewind, Heinrich, Jun., Susquehanna Silk Mills, 62, Greene Street, New York City, U.S.A., Vice-President and Treasurer.

1897. Schoder, Dr. Robt., 6, Brandreth Road, Balham, S.W., Chemist.

1904. Schoeller, Dr. Walter R., c/o D. C. Griffith & Co., Victoria Avenue, Bishopsgate Without, London, E.C., Analytical Chemist.

1902. Schofield, Jas. A., The University, Sydney, N.S.W., Australia, Lecturer in Chemistry.

O.M. Scholefield, H. E., Edge Hill Chemical Works, Liverpool, Chemical Manufacturer.

1898. Scholes, Geo. R., Dépôt Général de la Liebig's Extract of Meat Co., Ltd., Antwerp, Belgium, Analytical Chemist.

1906. Schramm, Quirin, Otto-Hilgenstock Coke Oven Co., Ltd., Tingley, near Wakefield, Chief Chemist.

1906. Schroeder, C. M. E., 221, Pearl Street, New York City, U.S.A., Analytical Chemist.

1895. Schroeder, E. August, c/o Church and Co., 36, Ash Street, Brooklyn, N.Y., U.S.A., Chemist.

1906. Schulten, Dr. C., 11, Clive Row, Calcutta, India, Analytical Chemist.

1904. Schultz, Carl R., 440, First Avenue, New York City, U.S.A., Mineral Water Manufacturer.

1901. Schultze, Wm., c/o General Chemical Co., Laurel Hill, Long Island, N.Y., U.S.A., Chemist.

1893. Schüpphaus, Dr. R. C., 175, Pearl Street, New York City, U.S.A., Consulting Chemist.

1893. Schwab, Dr. L. C., Sedanstrasse 53, Bernburg, Anhalt, Germany, Technical Chemist.

1902. Schwarz, Gustav A., Grasselli Chemical Co., 60, Wall Street, New York City, U.S.A., Manager.

1889. Schweich, Emile. *See* Mond, Emile S.

1903. Schweickert, Karl, 45, Hazelwood Avenue, Rahway, N.J., U.S.A., Chemist.

1894. Schweitzer, Dr. H., 128, Duane Street, New York City, U.S.A., Analytical Chemist.

1905. Schweizer, Alfred, 14, Rue de Calais, Paris, France.

1906. Schwerin, Lorenz R., c/o Casein Co. of America, Bainbridge, N.Y., U.S.A., Vice-President, Casein Co.

1906. Scott, Alex C., Davington House, Faversham, Kent, Assistant Manager (Cotton Powder Co.).
